ENCYCLOPÆDIA BRITANNICA.

NAVIGATION.

History. NAVIGATION is the art of conducting a ship from one port or place to another.

HISTORY.

The profane poets refer the invention of the art of navigation to their heathen deities, though historians ascribe it to the Æginetes, the Phœnicians, the Tyrians, and the ancient inhabitants of Britain. Scripture refers the origin of so useful an invention to God himself, who gave the first specimen of navigation in the ark built by Noah under his direction.

The earliest record of the practice of the art of navigation is that of the Egyptians, who at a very remote period are said to have established commercial relations with India. This traffic was carried on between the Arabian Gulf and the western coast of India, across the Indian Ocean. It would appear, however, that this intercourse was of no long duration, and that the Egyptians soon confined themselves to overland traffic with their neighbours, even excluding from all access to their country those foreigners who would have traded with them by the Mediterranean Sea.

The Phœnicians were the most distinguished of the early navigators; their commercial relations with other nations were the most widely spread; and their capital, Tyre, was for ages the centre of ancient commerce and the "mart of nations." The narrowness and poverty of the little slip of ground they possessed along the coast, and the convenience of two or three good ports, naturally drove an enterprising and industrious people, stimulated by a genius for commerce, to seek by sea those riches which were denied them by land. Accordingly, Lebanon and the other neighbouring mountains furnishing them with excellent wood for ship-building, they in a short time became masters of a numerous fleet; and constantly hazarding new navigations, and settling new trades, they soon arrived at an incredible pitch of opulence and populousness, insomuch as to be in a condition to send out colonies. The principal of these was Carthage, which, keeping up the Phœnician spirit of commerce, in time not only equalled Tyre itself, but vastly

surpassed it, sending its merchant fleets through the Straits of Gibraltar, along the western coasts of Africa and Europe, and even, if we may believe some authors, to America itself.

History.

At an early period of their history, although long subsequently to the rise of the Phœnician navigators, the Greeks learned and practised the art of navigating the adjacent seas, although they seem to have trusted almost entirely to the oar as the instrument of propulsion. The celebrated voyage of the Argonauts belongs to a very early period; and in later times the Corinthians and Corcyraeans disputed with Athens the empire of the Greek seas. At length Tyre, whose immense riches and power are represented in such lofty terms both by sacred and profane authors, was destroyed by Alexander the Great, upon which its navigation and commerce were transferred by the conqueror to Alexandria, a new city, admirably situated for these purposes, and intended to form the capital of the empire of Asia, of which Alexander then meditated the conquest. And thus arose the great navigation of the Egyptians, which was afterwards so much cultivated by the Ptolemies, that Tyre and Carthage were quite forgotten.

Egypt being reduced to a Roman province after the battle of Actium, its trade and navigation fell into the hands of Augustus, in whose time Alexandria was only inferior to Rome; and the magazines of the capital of the world were wholly supplied with merchandise from the commercial capital of Egypt.

At length Alexandria itself underwent the fate of Tyre and Carthage, being surprised by the Saracens, who, in spite of the Emperor Heraclius, overspread the northern coast of Africa. By them the merchants were expelled, and Alexandria was, until lately, in a languishing state; though it always had a considerable share of the commerce of the Christian merchants trading to the Levant. A fresh impulse, however, has been given of late years to the trade of Alexandria by its having become an important post in the overland route to India.

The fall of Rome and its empire drew along with it not only the overthrow of learning and the polite arts, but also that

History.

of navigation; the barbarians, into whose hands it fell, contenting themselves with the spoils of the industry of their predecessors. But no sooner were the braver amongst those nations well settled in their new provinces,—some in Gaul, as the Franks; others in Spain, as the Goths; and others in Italy, as the Lombards,—than they began to learn the advantages of navigation and commerce, and the methods of managing them, from the people they had subdued; and this with so much success, that in a little time some of them became able to give new lessons, and set on foot new institutions for its advantage. Thus it is to the Lombards that we usually ascribe the invention and use of banks, book-keeping, exchanges, rechanges, &c.

It does not appear which of the European people, after the settlement of their new masters, first betook themselves to navigation and commerce. Some think it began with the French, although the Italians seem to have the fairest title to this distinction, and are accordingly regarded as the restorers of navigation, as well as of the polite arts, which had been banished together from the time the empire was torn asunder. It is the people of Italy, then, and particularly those of Venice and Genoa, who have the merit of this restoration; and it is to their advantageous situation for navigation that they in great measure owe their glory. In the bottom of the Adriatic were a great number of marshy islands, only separated by narrow channels, but these well screened, and almost inaccessible, the residence of some fishermen, who here supported themselves by a little trade in fish and salt, which they found in some of these islands. Thither the Venetians, a people inhabiting that part of Italy which stretches along the coasts of the gulf, retired, when Alaric, King of the Goths, and afterwards Attila, King of the Huns, ravaged Italy.

These new islanders, little imagining that this was to be their fixed residence, did not think of composing any body politic; but each of the seventy-two islands of this little archipelago continued a long time under its separate master, and each formed a distinct commonwealth. When their commerce had become considerable enough to occasion jealousy to their neighbours, they began to think of uniting into a body; and it was this union, first begun in the sixth century, but not completed till the eighth, that laid the sure foundation of the future grandeur of the state of Venice. From the time of this union, their fleets of merchantmen were sent to all the ports of the Mediterranean; and at last to those of Egypt, particularly Cairo, a new city built by the Saracen princes, on the eastern bank of the Nile, where they traded for the spices and other products of the Indies. Thus they flourished and increased their commerce, their navigation, and their conquests, till the league of Cambray in 1508, when a number of jealous princes conspired to bring about their ruin. This was the more easily effected by the diminution of their East India commerce, of which the Portuguese had got one part and the French another.

Genoa, which had applied itself to navigation at the same time with Venice, and that with equal success, was a long time its dangerous rival, disputed with it the empire of the sea, and shared with it the trade of Egypt and other parts, both of the East and West. But jealousy soon broke out; and the two republics coming to an open rupture, there was almost continual war for three centuries. Towards the end of the fourteenth century, the battle of Chiozza ended the strife. The Genoese, who till then had usually the advantage, now lost all; and the Venetians, reduced almost to despair, secured to themselves, by one happy and unexpected blow, the foremost place in commerce and the sole empire of the sea.

About the same time that navigation was retrieved in the southern parts of Europe, a new society of merchants

was formed in the north, which not only carried commerce to the greatest perfection of which it was capable till the discovery of the East and West Indies, but also formed a new scheme of laws for its regulation, which still obtain under the name of Uses and Customs of the Sea.

This society is that famous league of the Hanse Towns, commonly supposed to have been instituted about the year 1164. (See HANSEATIC LEAGUE, and COMMERCE. For the present state of navigation in the various countries of the world, see under the name of each.)

We shall only add, that in examining the causes of commerce passing successively from the Venetians, Genoese, and Hanse Towns, to the Portuguese and Spaniards, and from these again to the English and Dutch, it may be established as a maxim, that the relation between commerce and navigation, or their union, is so intimate, that the fall of the one inevitably draws after it that of the other; and that they will always either flourish or decline together. Hence so many laws, ordinances, statutes, and edicts for its regulation; and hence particularly that celebrated act of navigation, which an eminent foreign author calls the *palladium or tutelar deity of the commerce of England*, which was long considered as the standing rule, not only of the British amongst themselves, but also as that of other nations with whom they trafficked.

The progress of political and commercial science, which gradually opened men's eyes to the great principle that all trade is most healthy and profitable when subjected to the fewest possible, and those only the most necessary, restrictions, resulted in the total repeal of these famous navigation laws in 1846, since which period trade with England has been free and open to all the world; but so far from British shipping and commerce being injured or diminished, they have been more prosperous since that repeal than they were at any former period, when most carefully fostered by protective laws.

The art of navigation has been exceedingly improved in modern times, both with regard to the form of the vessels themselves, and also with respect to the methods of working them. The use of rowers is now entirely superseded by the improvements made in the formation of the sails, rigging, &c.; by which means ships can not only sail much faster than formerly, but can tack in any direction with the greatest facility; and of late years the extensive and still growing employment of steam as the motive power, whether applied to paddle-wheels or screws, has further placed the mariner beyond the adverse retarding influence of calm and contrary winds, and has introduced an element of certainty and punctuality in commercial intercourse unknown at any previous period, and invaluable as it affects the interests of commerce. It is also very certain that the ancients were neither so well skilled in finding the latitudes, nor in steering their vessels in places of difficult navigation, as the moderns. But the greatest advantage which the moderns possess over the ancients consists in the mariner's compass, by which they are enabled to find their way with more facility in the midst of an immeasurable ocean, than the ancients could have done by creeping along the coast, and never going out of sight of land. Some people indeed contend that this is no new invention, but that the ancients were acquainted with it. They say, that it was impossible for Solomon to have sent ships to Ophir, Tarshish, and Parvaim, which last they imagine to have been Peru, without this useful instrument. They insist, that it was impossible for the ancients to be acquainted with the attractive virtue of the magnet, and to be ignorant of its polarity; nay, they affirm that this property of the magnet is plainly mentioned in the book of Job, where the loadstone is mentioned by the name of *topaz, or the stone that turns itself*. But it is certain that the Romans who conquered Judæa were ignorant of this instrument; and

History.

History. it is very improbable that such a useful invention, if it had once been commonly known to any nation, would have been forgotten, or perfectly concealed from such a prudent people as the Romans, who were so deeply interested in the discovery of it.

Amongst those who admit that the mariner's compass is a modern invention, it has been much disputed who was the inventor. Some attribute the honour of the discovery to Flavio Gioia of Amalfi in Campania, who lived about the beginning of the fourteenth century; whilst others contend that it came from the East, and was earlier known in Europe. But at whatever time it was invented, it is certain that the mariner's compass was not commonly used in navigation before the year 1420. In that year the science was considerably improved under the auspices of Henry, Duke of Visco, brother to the King of Portugal. In the year 1485, Roderick and Joseph, physicians to John II., King of Portugal, together with one Martin de Bohemia, a Portuguese native of the island of Fayal, and scholar of Regiomontanus, calculated tables of the sun's declination for the use of sailors, and recommended the astrolabe for taking observations at sea. Of the instructions of Martin the celebrated Christopher Columbus is said to have availed himself, and to have improved the Spaniards in the knowledge of the art; for the farther progress of which a lecture was afterwards founded at Seville by the Emperor Charles V.

The discovery of the variation is claimed both by Columbus and by Sebastian Cabot. The former certainly did observe the variation, without having heard of it from any other person, on the 14th of September 1492, and it is very probable that Cabot might have done the same. At that time it was found that there was no variation at the Azores, where some geographers have thought proper to place the first meridian, though it has since been observed that the variation alters in time. The use of the cross staff now began to be introduced amongst sailors. This ancient instrument is described by John Werner of Nuremberg, in his annotations on the first book of Ptolemy's *Geography*, printed in the year 1514. He recommends it for observing the distance between the moon and some star, in order thence to determine the longitude.

At this time the art of navigation was very imperfect, on account of the inaccuracies of the plane chart, which was the only one then known, and which, by its gross errors, must have greatly misled the mariner, especially in voyages far distant from the equator. Its precepts were probably at first only set down on the sea-charts, as is the custom at this day; but at length two Spanish treatises were published in the year 1545,—one by Pedro de Medina, and the other by Martin Cortes,—which contained a complete system of the art, as far as it was then known. These seem to have been the oldest writers who fully handled the art; for Medina, in his dedication to Philip, Prince of Spain, laments that multitudes of ships daily perished at sea, because there were neither teachers of the art, nor books by which it might be learned; and Cortes, in his dedication, boasts to the emperor that he was the first who had reduced navigation into a compendium, valuing himself much on what he had performed. Medina defended the plane chart; but he was opposed by Cortes, who showed its errors, and endeavoured to account for the variation of the compass by supposing the needle to be influenced by a magnetic pole (which he called the *point attractive*), different from that of the world, which notion has been farther prosecuted by others, and is now generally accepted as true in the scientific world. Medina's book was soon translated into Italian, French, and Flemish, and for a long time served as a guide to foreign navigators. Cortes, however, was the favourite author of the English nation, and was translated in the year 1561; whilst Medina's work

History. was entirely neglected, though translated also within a short time of the other. At that time the system of navigation consisted of an account of the Ptolemaic hypothesis, and the circles of the sphere; of the roundness of the earth, the longitudes, latitudes, climates, &c., and eclipses of the luminaries; a calendar; the method of finding the prime, epact, moon's age, and tides; a description of the compass, an account of its variation, for the discovery of which Cortes said that an instrument might easily be contrived; tables of the sun's declination for four years, in order to find the latitude from his meridian altitude; directions to find the same by certain stars; of the course of the sun and moon; the length of the days; of time and its divisions; the method of finding the hour of the day and night; and, lastly, a description of the sea chart, on which, in order to discover where the ship was, they made use of a small table, which showed, upon an alteration of one degree of the latitude, how many leagues were run in each rhumb, together with the departure from the meridian. Some other instruments were also described, especially by Cortes; such as one to find the place and declination of the sun, with the days and place of the moon; certain dials, the astrolabe, and cross staff; together with a complex machine to discover the hour and latitude at once.

About the same time proposals were made for finding the longitude by observations of the moon. In 1530 Gemma Frisius advised the keeping of time by means of small clocks or watches, which were then, as he says, newly invented. He also contrived a new sort of cross-staff, and an instrument called the *nautical quadrant*, which last was much praised by William Cunningham in his *Astronomical Glass*, printed in the year 1559.

In the year 1537, Pedro Nunez, or Nonius, published a book in the Portuguese language, to explain a difficulty in navigation proposed to him by the commander Don Martin Alphonso de Susa. In this he exposed the errors of the plane chart, and likewise gave the solution of several curious astronomical problems, amongst which was that of determining the latitude from two observations of the sun's altitude and the intermediate azimuth. He observed, that although the rhumbs are spiral lines, yet the direct course of a ship will always be in the arc of a great circle, whereby the angle with the meridians will continually change; and hence all that the steersman can here do for the preserving of the original rhumb, is to correct these deviations as soon as they appear sensible. But in reality the ship will thus describe a course without the rhumb line intended; and therefore his calculations for assigning the latitude, where any rhumb line crosses the several meridians, will be in some measure erroneous. He invented a method of dividing a quadrant by means of concentric circles, which, after having been much improved by Dr Halley, is used at present, and is called a *nonius*.

In the year 1577, William Bourne published a treatise in which, by considering the irregularities in the moon's motion, he showed the error of the sailors in finding her age by the epact, and also in determining the hour from observing on what point of the compass the sun and moon appeared. He advised, in sailing towards high latitudes, to keep the reckoning by the globe, as there the plane chart was most erroneous. He despaired of our ever being able to find the longitude, unless the variation of the compass should be occasioned by some such attractive point as Cortes had imagined, of which, however, he doubted; but as he had shown how to find the variation at all times, he recommended to keep an account of the observations, as useful for finding the place of the ship; and this advice was prosecuted at large by Simon Stevin, in a treatise published at Leyden in 1599, the substance of which was the same year printed at London in English by Edward Wright,

History. entitled the *Haven-finding Art*. In this ancient tract is also described the method by which our sailors estimate the rate of a ship in her course, by an instrument called the *log*. This was so named from the piece of wood or log which floats in the water, whilst the time is reckoned during which the line that is fastened to it is veering out. The inventor of this contrivance is not known; but it was first described in an account of an East India voyage published by Purchas in 1607, from which time it became famous, and was much taken notice of by almost all writers on navigation in every country. It still continues to be used as at first, although many attempts have been made to improve it, and contrivances proposed to supply its place, many of which have succeeded in quiet water, but proved useless in a stormy sea.

In the year 1581 Michael Coignet, a native of Antwerp, published a treatise, in which he animadverted on Medina. In this he showed, that as the rhumbs are spirals, making endless revolutions about the poles, numerous errors must arise from their being represented by straight lines on the sea charts; but although he hoped to find a remedy for these errors, he was of opinion that the proposals of Nonius were scarcely practicable, and therefore in a great measure useless. In treating of the sun's declination, he took notice of the gradual decrease in the obliquity of the ecliptic; he also described the cross staff with three transverse pieces, which he admitted were then in common use amongst the sailors. He likewise described some instruments of his own invention; but all of them are now laid aside, excepting perhaps his nocturnal. He constructed a sea table to be used by such as sailed beyond the sixtieth degree of latitude; and at the end of the book is delivered a method of sailing upon a parallel of latitude by means of a ring dial and a twenty-four hour glass. The same year the discovery of the dipping-needle was made by Robert Norman. In his publication on that subject he maintains, in opposition to Cortes, that the variation of the compass was caused by some point on the surface of the earth, and not in the heavens; and he also made considerable improvements on the construction of compasses themselves, showing especially the danger of not fixing, on account of the variation, the wire directly under the *fleur de lis*, as compasses made in different countries have it placed differently. To this performance of Norman's is prefixed a discourse on the variation of the magnetical needle, by William Burrough, in which he shows how to determine the variation in many different ways, and also points out many errors in the practice of navigation at that time, speaking in very severe terms concerning those who had published upon it.

During this time the Spaniards continued to publish treatises on the art. In 1585 an excellent *Compendium* was published by Roderico Zamorano, and contributed greatly towards the improvement of the art, particularly in the sea charts. Globes of an improved kind, and of a much larger size than those formerly used, were now constructed, and many improvements were made in other instruments; nevertheless, the plane chart continued still to be followed, though its errors were frequently complained of. Methods of removing these errors had indeed been sought after; and Gerard Mercator seems to have been the first who found the true method of effecting this, so as to answer the purposes of seamen. He represented the degrees both of latitude and longitude by parallel straight lines, but gradually augmented the space between the former as they approached the pole. Thus the rhumbs, which otherwise ought to have been curves, were now also extended into straight lines; and thus a straight line drawn between any two places marked upon the chart formed an angle with the meridians, expressing the rhumb leading from the one to the other. But although in 1569 Mercator published a universal map constructed in this manner, it does not appear that he was

History. acquainted with the principles upon which this proceeded; and it is now generally believed, that the true principles on which the construction of what is called *Mercator's Chart* depends, were first discovered by Edward Wright, an Englishman.

Wright supposed, but, according to the general opinion, without sufficient grounds, that this enlargement of the degrees of latitude was known and mentioned by Ptolemy, and that the same thing had also been spoken of by Cortes. The expressions of Ptolemy alluded to relate, indeed, to the proportion between the distances of the parallels and meridians; but instead of proposing any gradual widening between the parallels of latitude in a great circle, he speaks only of particular maps, and advises not to confine a system of such maps to one and the same scale, but to plan them out by a different measure, as occasion might require; with this precaution, however, that the degrees of longitude in each should bear some proportion to those of latitude, and this proportion was to be deduced from that which the magnitude of the respective parallels bore to a great circle of the sphere. He added, that, in particular maps, if this proportion be observed with regard to the middle parallel, the inconvenience will not be great, although the meridians should be straight lines parallel to each other. But here he is understood only to mean, that the maps should in some measure represent the figures of the countries for which they are drawn. In this sense Mercator, who drew maps for Ptolemy's tables, understood him; thinking it, however, an improvement not to regulate the meridians by one parallel, but by two, one distant from the northern, the other from the southern extremity of the map, by a fourth part of the whole depth; by which means, in his maps, although the meridians are straight lines, yet they are generally drawn inclining to each other towards the poles. With regard to Cortes, he speaks only of the number of degrees of latitude, and not of the extent of them; nay, he gives express directions that they should all be laid down by equal measurement in a scale of leagues adapted to the map.

For some time after the appearance of Mercator's map it was not rightly understood, and it was even thought to be entirely useless, if not detrimental. However, about the year 1592 its utility began to be perceived; and seven years afterwards Wright printed his famous treatise entitled *The Correction of certain Errors in Navigation*, where he fully explained the reason of extending the length of the parallels of latitude, and the use thereof to navigators. In 1610 a second edition of Wright's book was published, with improvements. An excellent method was proposed of determining the magnitude of the earth; and at the same time it was judiciously proposed to make our common measures in some proportion to a degree on its surface, that they might not depend on the uncertain length of a barleycorn. Amongst his other improvements may be mentioned the Table of Latitudes for Dividing the Meridian computed to Minutes, whereas it had been only divided to every tenth minute. He also published a description of an instrument which he calls the *sea ring*, by which the variation of the compass, the altitude of the sun, and the time of the day, may at once readily be determined in any place, provided the latitude is known. He also showed how to correct the errors arising from the eccentricity of the sun, in observing by the cross staff. In the years 1594, 1595, 1596, and 1597, he amended the tables of the declinations and places of the sun and stars from his own observations made with a six-feet quadrant, a sea quadrant to take altitudes by a forward or backward observation, and likewise with a contrivance for the ready finding of the latitude by the height of the pole-star, when not upon the meridian. To this edition was subjoined a translation of Zamorano's *Compendium*, above mentioned, in which he corrected some

History. mistakes in the original, adding a large table of the variation of the compass observed in different parts of the world, in order to show that it was not occasioned by any magnetical pole.

These improvements soon became known abroad. In 1608 a treatise, entitled *Hypomnemata Mathematica*, was published by Simon Stevin for the use of Prince Maurice. In the portion of the work relating to navigation, the author treated of sailing on a great circle, and showed how to draw the rhumbs on a globe mechanically; he also set down Wright's two tables of latitudes and of rhumbs, in order to describe these lines more accurately; and even pretended to have discovered an error in Wright's table. But Stevin's objections were fully answered by the author himself, who showed that they arose from the rude method of calculating made use of by the former.

In 1624 the learned Willebrordus Snellius, professor of mathematics at Leyden, published a treatise of navigation on Wright's plan, but somewhat obscurely; and as he did not particularly mention all the discoveries of Wright, the latter was thought by some to have taken the hint of all his discoveries from Snellius. But this supposition has been long ago refuted; and Wright's title to the honour of those discoveries remains unchallenged.

Having shown how to find the place of the ship upon his chart, Wright observed that the same might be performed more accurately by calculation; but considering, as he says, that the latitudes, and especially the courses at sea, could not be determined so precisely, he forbore setting down particular examples; as the mariner may be allowed to save himself this trouble, and only to mark out upon his chart the ship's way, after the manner then usually practised. However, in 1614, Raphe Handson, amongst the nautical questions which he subjoined to a translation of Pitiscus's *Trigonometry*, solved very distinctly every case of navigation, by applying arithmetical calculations to Wright's *Tables of Latitudes*, or of Meridional Parts, as it has since been called. Although the method discovered by Wright for finding the change of longitude by a ship sailing on a rhumb is the proper way of performing it, Handson also proposes two methods of approximation without the assistance of Wright's division of the meridian line. The first was computed by the arithmetical mean between the cosines of both latitudes; and the other by the same mean between the secants, as an alternative when Wright's book was not at hand; although this latter is wider of the truth than the former. By the same calculations also he showed how much each of these compends deviates from the truth, and also how widely the computations on the erroneous principles of the plane chart differ from them all. The method generally used by our sailors, however, is commonly called the *middle latitude*, which, although it errs more than that by the arithmetical mean between the two cosines, is preferred on account of its being less operative; yet in high latitudes it is more eligible to use that of the arithmetical mean between the logarithmic cosines, equivalent to the geometrical mean between the cosines themselves—a method since proposed by John Bassat. The computation by the middle latitude will always fall short of the true change of longitude, that by the geometrical mean will always exceed; but that by the arithmetical mean falls short in latitudes of about 45° , and exceeds in lesser latitudes. However, none of these methods will differ much from the truth when the change of latitude is sufficiently small.

About this period logarithms were invented by John Napier, Baron of Merchiston in Scotland, and proved of the utmost service to the art of navigation. From these Edmund Gunter constructed a table of logarithmic sines

and tangents to every minute of the quadrant, which he published in 1620. In this work he applied to navigation, and other branches of mathematics, his admirable ruler known by the name of Gunter's Scale,¹ on which are described lines of logarithms, of logarithmic sines and tangents, of meridional parts, &c.; and he greatly improved the sector for the same purposes. He also showed how to take a back observation by the cross staff, by which the error arising from the eccentricity of the eye is avoided. He likewise described another instrument, of his own invention, called the *cross bow*, for taking altitudes of the sun or stars, with some contrivances for more readily finding the latitude from the observation. The discoveries concerning logarithms were carried into France in 1624 by Edmund Wingate, who published two small tracts in that year at Paris. In one of these he taught the use of Gunter's scale; and in the other, that of the tables of artificial sines and tangents, as modelled according to Napier's last form, erroneously attributed by Wingate to Briggs.

Gunter's scale was projected into a circular arch by the Reverend William Oughtred in 1633; and its uses were fully shown in a pamphlet entitled *The Circles of Proportion*, where, in an appendix, several important points in navigation are well treated. It has also been made in the form of a sliding ruler.

The logarithmic tables were first applied to the different cases of sailing, by Thomas Addison, in his treatise entitled *Arithmetical Navigation*, printed in the year 1625. He also gave two traverse tables, with their uses; the one to quarter points of the compass, and the other to degrees. Henry Gellibrand published his discovery of the changes of the variation of the compass, in a small quarto pamphlet, entitled *A Discourse Mathematical on the Variation of the Magnetical Needle*, printed in 1635. This extraordinary phenomenon he found out by comparing the observations which had been made at different times near the same place by Burrough, Gunter, and himself, all persons of great skill and experience in these matters. This discovery was likewise soon known abroad; for Athanasius Kircher, in his treatise entitled *Magnes*, first printed at Rome in the year 1641, informs us that he had been told of it by John Greaves, and then gives a letter of the famous Marinus Mersennus, containing a very distinct account of the same.

As altitudes of the sun are taken on shipboard by observing his elevation above the visible horizon, to obtain from these the sun's true altitude with correctness, Wright observed it to be necessary that the dip of the visible horizon below the horizontal plane passing through the observer's eye should be brought into the account, which cannot be calculated without knowing the magnitude of the earth. Hence he was induced to propose different methods for finding this; but he complains that the most effectual was out of his power to execute, and therefore he contented himself with a rude attempt, in some measure sufficient for his purpose. The dimensions of the earth deduced by him corresponded very well with the usual divisions of the log-line; nevertheless, as he did not write an express treatise on navigation, but only for correcting such errors as prevailed in general practice, the log-line did not fall under his notice. Richard Norwood, however, put in execution the method recommended by Wright as the most perfect for measuring the dimensions of the earth, with the true length of the degrees of a great circle upon it; and in 1635 he actually measured the distance between London and York; from which measurement, and the summer solstitial altitudes of the sun observed on the meridian at both places, he found a degree on a great circle of the earth to contain 367,196 English feet, equal to 57,300 French

¹ See GUNTER'S SCALE.

History.

fathoms or toises; which is very exact, as appears from many measurements that have been made since that time. Of all this Norwood gave a full account in his treatise called the *Seaman's Practice*, published in 1657. He there showed the reason why Snellius had failed in his attempt; and he also pointed out various uses of his discovery, particularly for correcting the gross errors hitherto committed in the divisions of the log-line. But necessary amendments have been little attended to by sailors, whose obstinacy in adhering to established errors has been complained of by the best writers on navigation. This improvement, however, has at length made its way into practice; and few navigators of reputation now make use of the old measure of forty-two feet to a knot. In this treatise Norwood also describes his own excellent method of setting down and perfecting a sea reckoning, by using a traverse table, which method he had followed and taught for many years. He likewise shows how to rectify the course, by taking into consideration the variation of the compass; as also how to discover currents, and to make proper allowance on their account. This treatise, and another on Trigonometry, were continually reprinted, as the principal books for learning scientifically the art of navigation. What he had delivered, especially in the latter of them, concerning this subject, was abridged as a manual for sailors, in a very small work called an *Epitome*; which useful performance has gone through a great number of editions. No alterations were ever made in the *Seaman's Practice* till the twelfth edition in 1676, when the following paragraph was inserted in a smaller character:—"About the year 1672, Monsieur Picart has published an account in French concerning the measure of the earth, a brief of whereof may be seen in the *Philosophical Transactions*, No. 112, wherein he concludes one degree to contain 365,184 English feet, nearly agreeing with Mr Norwood's experiment;" and this advertisement is continued through the subsequent editions as late as the year 1732.

About the year 1645, Bond published, in Norwood's *Epitome*, a very great improvement of Wright's method, from a property in his meridian line, whereby the divisions are more scientifically assigned than the author himself was able to effect. It resulted from this theorem, that these divisions are analogous to the excesses of the logarithmic tangents of half the respective latitudes augmented by 45° above the logarithm of the radius. This he afterwards explained more fully in the third edition of Gunter's works, printed in 1653, where he observed that the logarithmic tangents from 45° upwards increase in the same manner as the secants do added together, if every half degree be accounted as a whole degree of Mercator's meridional line. His rule for computing the meridional parts belonging to any two latitudes, supposed to be on the same side of the equator, is to the following effect:—"Take the logarithmic tangent, rejecting the radius, of half each latitude, augmented by 45° ; divide the difference of those numbers by the logarithmic tangent of $45^\circ 30'$, the radius being likewise rejected, and the quotient will be the meridional parts required, expressed in degrees." This rule is the immediate consequence of the general theorem, that the degrees of latitude bear to one degree (or sixty minutes, which in Wright's table stand for the meridional parts of one degree) the same proportion as the logarithmic tangent of half any latitude augmented by 45° , and the radius neglected, to the like tangent of half a degree augmented by 45° , with the radius likewise rejected. But here there was still wanting the demonstration of this general theorem, which was at length supplied by James Gregory of Aberdeen, in his *Exercitationes Geometricæ*, printed at London in 1668; and afterwards more concisely demonstrated, together with a scientific determination of the divisor, by Dr Halley, in the *Philosophical*

History.

Transactions for 1695 (No. 219), from the consideration of the spirals into which the rhumbs are transformed in the stereographic projection of the sphere upon the plane of the equinoctial, and which is rendered still more simple by Roger Cotes, in his *Logometria*, first published in the *Philosophical Transactions* for 1714 (No. 348). It is, moreover, added in Gunter's book, that if $\frac{1}{2}$ of this division, which does not sensibly differ from the logarithmic tangent of $45^\circ 1' 30''$, with the radius subtracted from it, be used, the quotient will exhibit the meridional parts expressed in leagues; and this is the divisor set down in Norwood's *Epitome*. After the same manner, the meridional parts will be found in minutes, if the like logarithmic tangent of $45^\circ 1' 30''$, diminished by the radius, be taken; that is, the number used by others being 12633, when the logarithmic tables consist of eight places of figures besides the index.

In an edition of a book called the *Seaman's Kalendar*, Bond declared that he had discovered the longitude by having found out the true theory of the magnetic variation; and to gain credit to his assertion, he foretold, that at London in 1657 there would be no variation of the compass, and from that time it would gradually increase the other way; which happened accordingly. Again, in the *Philosophical Transactions* for 1668 (No. 40), he published a table of the variation for forty-nine years to come. Thus he acquired such reputation, that his treatise entitled *The Longitude Found*, was, in the year 1676, published by the special command of Charles II., and approved by many celebrated mathematicians. It was not long, however, before it met with opposition; and in the year 1678 another treatise, entitled *The Longitude not Found*, made its appearance; and as Bond's hypothesis did not answer its author's sanguine expectations, the solution of the difficulty was undertaken by Dr Halley. The result of his speculation was, that the magnetic needle is influenced by four poles; but this wonderful phenomenon seems hitherto to have eluded all our researches. (See MAGNETISM.) In 1700, however, Dr Halley published a general map, with curve lines expressing the paths where the magnetic needle had the same variation; which was received with universal applause. But as the positions of these curves vary from time to time, they should frequently be corrected by skilful persons, as was done in 1681 and 1700, by Mountain and Dodson. In the *Philosophical Transactions* for 1690, Dr Halley also gave a dissertation on the monsoons, containing many very useful observations for such as sail to places subject to these winds.

After the true principles of the art were settled by Wright, Bond, and Norwood, new improvements were daily made, and everything relative to it was settled with an accuracy not only unknown to former ages, but which would have been reckoned utterly impossible. The earth being found to be, not a perfect sphere, but a spheroid, with the shortest diameter passing through the poles, a tract was published in 1741 by the Reverend Dr Patrick Murdoch, wherein he accommodated Wright's sailing to such a figure; and the same year Colin Maclaurin, in the *Philosophical Transactions* (No. 461), gave a rule for determining the meridional parts of a spheroid; which speculation is farther treated of in his book of *Fluxions*, printed at Edinburgh in 1742, and in Delambre's *Astronomy* (t. iii., ch. xxxvi.).

Amongst the later discoveries in navigation, that of finding the longitude, both by lunar observations and by time-keepers, is the principal. It is owing chiefly to the rewards offered by the British Parliament that this has attained the present degree of perfection. We are indebted to Dr Maskelyne for putting the first of these methods in practice, and for other important improvements in navigation. The time-keepers constructed by Harrison for this express

Practice of purpose were found to answer so well that he obtained the parliamentary reward. These have been improved by Arnold, Earnshaw, and many others, so as now to be almost in common use.

The works which have latterly appeared on navigation are those on the longitude and navigation by Mackay, Inman, Riddle, Norie, Jeans, and others; and these contain every necessary requisite to form the practical navigator.

PRACTICE OF NAVIGATION.

BOOK I.

CONTAINING THE VARIOUS METHODS OF SAILING.

The art of navigation depends upon mathematical and astronomical principles. The problems in the various modes of sailing are resolved either by trigonometrical calculations, or by tables or rules formed by the assistance of plane and spherical trigonometry. By mathematics the necessary tables are constructed and rules investigated for performing the more difficult parts of navigation.

The places of the sun, moon, and planets, and fixed stars, are deduced from observation and calculation, and arranged in tables, the use of which is absolutely necessary in reducing observations taken at sea for the purpose of ascertaining the latitude and longitude of the ship and the variation of the compass. The investigation of the rules required for this purpose belongs properly to the science of ASTRONOMY, to which the reader is referred. A few tables are given at the end of this article, but as the other tables necessary for the practice of navigation are to be found in almost every treatise on this subject, it seems unnecessary to insert them in this place. The subject naturally divides itself under two heads:—*First*, The methods of conducting a ship from one port to another by help of rules, in which the log-line and compass are alone required, which is *Navigation* properly so called. *Second*, The method of ascertaining the ship's latitude and longitude, and variation of compass, by means of observations on the heavenly bodies; and the rules for that purpose deduced from astronomy, in order to correct the ship's place, and the courses derived from the former method, to which the name of *Nautical Astronomy* is generally applied. Although the reader is referred to the respective articles on the sciences on which navigation is founded in this work for complete information, we shall, nevertheless, endeavour to make our explanation of the several rules as complete as possible, even at the risk of repeating somewhat the substance of portions of our other articles.

CHAP. I.—PRELIMINARY PRINCIPLES.

SECT. I.—ON LATITUDE AND LONGITUDE; DEFINITION OF TERMS USED IN NAVIGATION; AND GENERAL EXPLANATIONS.

1. *Latitude and Longitude.*

The situation of a place, or any object on the earth's surface, is estimated by its distance from two imaginary lines on that surface intersecting each other at right angles. The one of these is called the *Equator*, and the other the *First Meridian*. The situation of the equator is fixed; but that of the first meridian is arbitrary, and therefore different nations assume different first meridians. In Great Britain we assume that to be the first meridian which passes through the Royal Observatory at Greenwich.

The equator is a great circle on the earth's surface, every point of which is equally distant from the two poles or the extremities of the imaginary axis about which the earth makes her diurnal rotation. It therefore divides the earth into two equal parts, called the *Northern* and the *Southern*

Hemispheres, according as the *North* or the *South Pole* lies within them.

The latitude of a place is its distance from the equator, reckoned on a meridian in degrees, minutes, and seconds, and decimal parts of seconds (if necessary), being either north or south, according as it is the Northern or Southern Hemisphere. Hence it appears that the latitudes of all places are comprised within the limits 0° and 90° N., and 0° and 90° S.

The first meridian, which is a great circle passing through the poles, also divides the earth into two equal portions, called the *Eastern* and *Western Hemispheres*, according as they lie to the *right* or *left* of the first meridian; the spectator being supposed to be looking towards the north.

The longitude of a place is the arc of the equator intercepted between the first meridian and the meridian of the given place reckoned in degrees, minutes, and seconds; and is either east or west as the place lies in the Eastern or Western Hemisphere respectively to the first meridian. The longitude of all places on the earth's surface is comprised within the limits of 0° and 180° E., and 0° and 180° W.

On the supposition that the earth is a sphere, the length of all arcs of great circles upon it subtending an angle of 1° at the centre are equal; hence 1° of latitude or longitude is equal to one geographical or nautical mile, of which a degree contains 60. Hence intervals of latitude and longitude, reduced to minutes and parts of minutes, also represent the same number of nautical miles and parts of a nautical mile.

In the practice of navigation, the latitude and longitude of the place which a ship leaves, are called the latitude and longitude *from*; and the latitude and longitude of the place at which it has arrived, are called the latitude and longitude *in*.

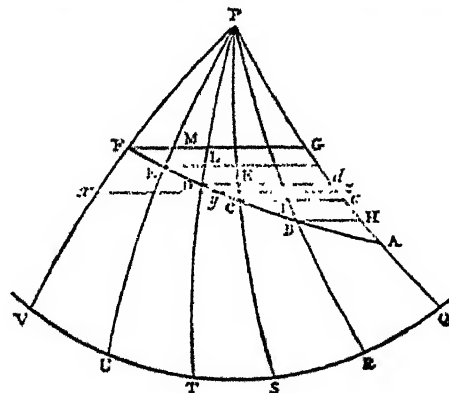

Fig. 1.

2. *Definitions of Terms used in Navigation, and Explanations.*

Let QR...V be a portion of the equator, P the pole, and PAQ, PBR, PCS.....PFV be meridians supposed very near to one another, passing through points A, B, C, D, E, F, the line AF being the path traced out by a vessel in passing from A to F, such that it makes equal angles with every meridian over which it passes. From B, C, D, &c., let BH, CI, DK, EL, &c., be drawn perpendicular to the

Preliminary Principles.

two meridians between which they respectively lie; or, in other words, be arcs of small circles or parallels of latitude through the points B, C, &c. These are consequently all parallel to one another, and to FG the whole arc of the parallel at F included between the extreme meridians PAQ and PFV.

The constant angle at which the line AF is inclined to the successive meridians, viz., BAP, CBP, DCP, &c., is called the *course*. Also, if the small circles or parallels at B, C, &c., be continued to the meridian PAQ, the portion of this meridian intercepted between any two consecutive parallels, as *cd*, will be equal to CK, the distance between the parallels through C and D; and so on for all. Hence the sum of these distances, AH + BI + CK + DI + EM = AG; which is called the *true difference of latitude*, or true diff. lat. from A to F.

The corresponding arcs of parallels at different latitudes intercepted between the same meridians are not equal, but gradually decrease from the equator to the poles. Hence the sum of the arcs BH + CI + DK + EL + FM is less than QV, the intercepted arc of the equator, but greater than FG, the arc of the highest parallel intercepted between PAQ and PFV.

BH + CI + DK + EL + FM is called the *departure*; the arc QV of the equator is the *difference of longitude*; and AF, the curve described by the vessel in passing from A to F, is called the *distance*.

In navigation, each of the triangles ABH, BCI, &c., is considered as a plane triangle; and as each of them is right-angled, and contains, besides, one constant angle, viz., the course, the other angle in each must also be constant; and all the triangles will be equiangular and similar. Hence we have

$$\begin{aligned} AH : BH : AB &:: AH : BH : AB \\ BI : CI : BC &:: AH : BH : AB \\ CK : DK : CD &:: AH : BH : AB \\ &\&c. \quad \&c. \quad \&c. \\ EM : FM : EF &:: AH : BH : AB. \end{aligned}$$

And since, when any number of quantities are in continued proportion, as the first consequent is to its antecedent, so are all the consequents to all the antecedents; we have

$$AH + BI + CK + \&c. : BH + CI + DK + \&c. : AB + BC + CD + \&c. \\ :: AH : BH : AB.$$

But AH + BI + CK + &c. = AG the true diff. lat.

BH + CI + DK + &c. = the departure.

AB + BC + CD + &c. = AF the distance.

Hence the true difference of latitude, departure, and distance, may be considered as the sides of a right-angled triangle, similar to each of the small triangles; the angle of which, therefore, between the true difference of latitude and distance, is the course.

Take AB (fig. 2) = the true diff. lat. Draw BC at right angles to it = departure. Join AC. Then AC is the distance, and BAC is the course.

From this it appears, that when any two of the four quantities, true difference of latitude, departure, distance, and course are given, the remaining two can be found by solving the right-angled triangle ABC.

1. Given course (BAC) and distance (AC), to find true difference of latitude (AB), and departure (BC).

$$\begin{aligned} AB &= AC \cos BAC \\ BC &= AC \sin BAC, \end{aligned}$$

$$\begin{aligned} \text{i.e., true diff. lat. (in miles)} &= \text{dist.} \times \cos \text{course} \quad . \quad (i.) \\ \text{and departure} &= \text{dist.} \times \sin \text{course} \quad . \quad (ii.) \end{aligned}$$

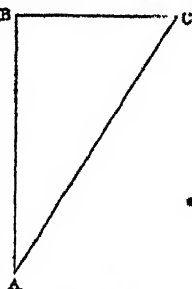

Fig. 2.

Or in logarithms,

$\log. \text{ true diff. lat.} = \log. \text{ dist.} + L \cos \text{ course} - 10,$
where L means tabular logarithm, i.e., logarithm increased by 10; and $\log. \text{ dep.} = \log. \text{ dist.} + L \sin \text{ course} - 10.$

Preliminary Principles.

2. Given course (BAC) and true difference of latitude (AB), to find distance and departure.

$$AC = AB \times \sec BAC$$

$$BC = AB \times \tan BAC;$$

$$\text{or dist.} = \text{true diff. lat.} \times \sec \text{ course} \quad . \quad . \quad . \quad (iii.)$$

$$\text{dep.} = \text{true diff. lat.} \times \tan \text{ course} \quad . \quad . \quad . \quad (iv.)$$

3. Given course and departure, to find distance and true difference of latitude.

$$AC = BC \times \csc BAC$$

$$AB = BC \times \cot BAC;$$

$$\text{or dist.} = \text{dep.} \times \csc \text{ course} \quad . \quad . \quad . \quad (v.)$$

$$\text{and true diff. lat.} = \text{dep.} \times \cot \text{ course} \quad . \quad . \quad . \quad (vi.)$$

4. Given distance and true difference of latitude, to find course and departure.

$$\cos BAC = \frac{AB}{AC};$$

$$\text{or cosine course} = \frac{\text{true diff. lat.}}{\text{dist.}} \quad (vii.)$$

And the course having been found, we get

$$\text{dep.} = \text{dist.} \times \sin \text{ course by (ii.)}$$

5. Given the distance and departure, to find the course and true difference of latitude.

$$\sin BAC = \frac{BC}{AC};$$

$$\text{or sin course} = \frac{\text{dep.}}{\text{distance}} \quad (viii.)$$

And then we have

$$\text{true diff. lat.} = \text{dist.} \times \cos \text{ course.}$$

6. Given the true difference of latitude and course, to find the course and distance.

$$\tan BAC = \frac{BC}{AB};$$

$$\text{or tan course} = \frac{\text{dep.}}{\text{true diff. lat.}} \quad (ix.)$$

And having found the course, we have

$$\text{dist.} = \text{true diff. lat.} \times \sec \text{ course by (iii.)}$$

$$\text{or dist.} = \text{dep.} \times \csc \text{ course by (v.)}$$

Length of Arc of 1° of Parallels of Latitude.

We have already stated that the lengths of the parallels of latitude diminish as the latitude increases. In fact, it decreases in the ratio of cosine latitude to unity.

Let EQ be the equator, PCP the polar diameter of the earth passing through C, and LML any parallel of latitude. Let the angle ECL, or the latitude, be l , and let LM and EF be the arcs of the parallel and of the equator intercepted between the meridians PEP' and PFP'. Then angle ECF = angle LOM, because they both measure the angle between the planes of the two meridians. Hence

$$\text{arc LM} : \text{arc EF} :: OL : CE :: OL : CL, \text{ because } CE = CL;$$

$$\text{or arc LM} = \text{arc EF} \times \frac{OL}{CL} = \text{arc EF} \times \sin OCL.$$

$$= \text{arc EF} \times \cos LCE = \text{arc EF} \times \cos l.$$

Hence if FE be the length of an arc 1° of longitude at the equator, or 60 miles, LM the length of an arc 1° of longitude in latitude $l = 60 \times \cos l$.

Preliminary principles.

Middle Latitude.

The departure is less than VQ (fig. 1), the intercepted arc of the equator, or than the intercepted arc of the parallel through A; but it is greater than FG. But since the arc of the parallel gradually decreases from A to F, there is some point intermediate in position between A and F (y), the intercepted arc of the parallel of which will be exactly equal to the departure. The exact determination of this point is not very easy. Various methods have been proposed to determine this latitude nearly, with as little trouble as possible: first, by taking the arithmetical mean of the two latitudes for that of the mean latitude; secondly, by using the arithmetical mean of the cosines of the latitudes; thirdly, by using the geometrical mean of these cosines; and, lastly, by employing the latitude deduced from the mean of the meridional parts of the two latitudes. The first of these methods is the one usually employed. It has the merit of great simplicity; and as all the rules in navigation are approximate only, it may perhaps be depended on as much as any of these. Hence y may be considered as the middle point between A and F; and $\text{dep.} = xyz$.

But $xyz = VQ \cos \text{lat. of } y$;

or $\text{dep.} = \text{diff. long.} \times \cos y$, where y is the arithmetical mean of the latitudes of A and F = $\frac{1}{2}(l + l')$, if

$l = \text{latitude of A,}$

$l' = \text{latitude of F.}$

This is commonly called the *middle latitude*. Hence we have $\text{dep.} = \text{diff. long.} \times \cos \text{middle latitude.}$

By equation (1.) we have

$\text{true diff. lat.} = \text{dist.} \times \cos \text{course.}$

Whence it appears that if the middle latitude be considered as a course, and the departure as a true difference of longitude, the corresponding distance will be the difference of longitude. And conversely, treating the middle latitude as a course, and the difference of longitude as a distance, the corresponding true difference of latitude will be the departure.

Mercator's Chart—Meridional Parts.

The chart used at sea for tracing the ship's track exhibits the surface of the earth on a plane, in which the meridians are parallel, and consequently the distance between them throughout their length equal to the equatorial distance, instead of gradually decreasing as the latitude increases. In other words, FG is increased so as to become equal to VQ. Now, in order that on this chart all points may occupy the same relative position with respect to each other that the points corresponding to them do on the surface of the globe, the distance AF and the distance AG must be increased in the same proportion that BII + CI + DK + &c., i.e., the departure has been increased.

The distance AG so increased is called the *meridional difference of latitude*, or mer. diff. lat.; and the chart constructed on this principle is called Mercator's Chart. If for any latitude the meridional difference of latitude between this point and the equator be expressed in miles or minutes, the number of miles so expressed is called the *meridional parts* for that latitude. A table of meridional parts for every minute of latitude from 0° up to 90° , is given in every collection of nautical tables.

Construction of Table of Meridional Parts.

This table may be constructed approximately, by dividing the whole meridian from 0° to 90° into intervals of $1'$, and supposing the increase of the arc of the parallel of latitude, and consequently that of the arc of latitude, to take place at the end of the successive minutes.

Now we have seen that an arc of any parallel = corresponding arc of equator $\times \cos \text{lat.}$; and since the arcs of the successive parallels have all become equal to the correspond-

VOL. XVI.

ing arc of the equator, they have all been increased in the ratio of $\sec \text{lat.}$ to 1.

Hence, if the length of $1'$ of the meridian be 1, and a, b, c, d , the corresponding increased lengths between 0 and $1'$, between $1'$ and $2'$, $2'$ and $3'$, &c.,

$$a = 1 \times \sec 1'$$

$$b = 1 \times \sec 2'$$

$$c = 1 \times \sec 3'$$

$$d = 1 \times \sec 4'$$

$$\&c. \quad \&c.$$

And $a + b + c, \&c. = \sec 1' + \sec 2' + \sec 3' + \&c.$; or the meridional parts in any arc of the meridian is equal to the sum of the secants of all the successive angles, differing by $1'$, from $1'$ up to the given latitude.

The true investigation is as follows:—Let m = the circular measure of the angle subtended at the centre by the meridional parts in the arc between the latitudes 0 and l ; and let l become $l + \delta l$, and let δm be the corresponding increase of m . Then δm is proportional to the secant of $l + \delta l$;

$$\text{or } \frac{\delta m}{\delta l} = \sec (l + \delta l).$$

And ultimately taking the limit

$$\frac{dm}{dl} = \sec l;$$

$$\therefore m = \int_0^l \sec l \, dl = \int_0^l \frac{1}{\cos l} \, dl$$

$$= \int_0^l \frac{\cos^2 \frac{l}{2} - \sin^2 \frac{l}{2}}{\cos^2 \frac{l}{2} - \sin^2 \frac{l}{2}} \, dl = \int_0^l \frac{\left(1 + \tan^2 \frac{l}{2}\right) dl}{1 - \tan^2 \frac{l}{2}}$$

$$= 2 \int_0^l \frac{d \cdot \tan \frac{l}{2}}{1 - \tan^2 \frac{l}{2}} = \log_e \frac{1 + \tan \frac{l}{2}}{1 - \tan \frac{l}{2}}$$

$$= \log_e \left(\frac{\cos \left(45 - \frac{l}{2}\right)}{\cos 45 + \frac{l}{2}} \right)$$

$$\text{Let } 45 - \frac{l}{2} = \frac{l_1}{2}, \text{ or } 90 - l = l_1;$$

$$45 + \frac{l}{2} = 90 - \frac{l_1}{2};$$

$$\text{and } m = \log_e \frac{\cos \frac{l_1}{2}}{\sin \frac{l_1}{2}} = \log_e \cot \frac{l_1}{2}$$

$$= 2.3025851 \log_{10} \cot \frac{1}{2} l_1.$$

$$\text{Now } m = \frac{\text{arc}}{\text{radius}} = \frac{\text{arc (in minutes)}}{\text{radius (in miles)}} = \frac{\text{meridional parts for lat. } l}{57.29577 \times 60}$$

\therefore meridional parts for lat. l

$$= 57.29577 \times 60 \times 2.3025851 \times \log_{10} \cot \frac{1}{2} l_1.$$

In logarithms—

$$\log \text{ mer. parts for lat. } l = 3.8984895 + \log_{10} (\text{L cot } \frac{1}{2} \text{ colat.} - 10).$$

Whence we deduce the following

Rule for Finding the Meridional Parts.

Diminish the tabular logarithm of the cotangent of one-half the colatitude by 10. Find the logarithm of the remainder, and add to it the constant logarithm 3.8984895. The result is the logarithm of the meridional parts for the given latitude.

Preliminary principles.

Preliminary principles.

Ex.—Required the meridional parts for latitude 65° and $65^{\circ} 20'$.

$$\begin{aligned} L \cot 12^{\circ} 30' - 10 &= 0.6512448 \\ \text{Log. } 0.6512448 &= \overline{1}^{\circ} 8157403 \\ \text{Constant log.} &= 3.8984895 \\ &= 3.7142298 \\ \therefore \text{Meridional parts,} &= 5178.80 \\ \\ L \cot 12^{\circ} 20' - 10 &= 0.6602609 \\ \text{Log. } 0.6602609 &= \overline{1}^{\circ} 8197155 \\ \text{Constant log.} &= 3.8984895 \\ &= 3.7182050 \\ \therefore \text{Meridional parts,} &= 5226.43 \end{aligned}$$

Relations between Meridional Difference of Latitude and Difference of Longitude, Course, &c.

It appears that on Mercator's chart the difference of longitude, meridional difference of latitude, and increased distance, form the sides of a right-angled triangle, and are proportional to the departure, true difference of latitude, and distance, in the triangle ABC. The two triangles are therefore similar.

If, then, in AB produced (fig. 4) AB' be taken equal to mer. difference of latitude, and B'C' be drawn parallel to BC, meeting AC produced in C'; the sides of the triangle AB'C' will be the meridional difference of latitude, difference of longitude, and increased distance.

Hence, in equations (i.), (ii.), (iii.), (iv.), (v.), (vi.), (vii.), and (viii.), we may substitute meridional difference of latitude for true difference of latitude, difference of longitude for departure, and increased distance for distance; and the equations will still hold.

The relation principally required is that which connects the meridional difference of latitude, difference of longitude, and course;

$$\text{or, diff. long.} = \text{mer. diff. lat.} \times \tan \text{course.}$$

Parallel Sailing.

When the course is 90° , or the ship sails in a parallel of latitude, the equations (i.), &c., give no result when applied to find the distance.

In this case we must apply the formula, arc of parallel = corresponding arc of equator $\times \cos \text{lat.}$ Here the arc of the parallel corresponds to the distance, and the arc of equator is difference of longitude, and we have for parallel sailing

$$\text{dist.} = \text{diff. long.} \times \cos \text{lat.},$$

from which, any two of the quantities being given, the third may be found. Also, if d and d' be distances corresponding to the same difference of longitude in parallels l and l' ,

$$\text{we have } d = \text{diff. long.} \cos l;$$

$$d' = \text{diff. long.} \cos l';$$

$$\therefore \text{or } d = d' \cdot \frac{\cos l}{\cos l'};$$

which enables us to find the distance on one parallel corresponding to a given distance on another, the difference of longitude being the same.

Middle-Latitude Sailing.

Since departure = diff. of longitude $\times \cos \text{mid. latitude}$, if in equations (ii.), (iv.), (vi.), (viii.), we substitute this value for departure, we shall obtain the following equations:—

$$\begin{aligned} \text{diff. long.} \times \cos \text{mid. lat.} &= \text{dist.} \times \sin \text{course} & \text{(xi.)} \\ \text{diff. long.} \times \cos \text{mid. lat.} &= \text{true diff. lat.} \times \tan \text{course} & \text{(xii.)} \\ \text{true diff. lat.} &= \text{diff. long.} \times \cos \text{mid. lat.} \times \cot \text{course} & \text{(xiii.)} \\ \sin \text{course} &= \text{diff. long.} \times \cos \text{mid. lat.} \div \text{dist.} & \text{(xiv.)} \end{aligned}$$

from which all the rules for middle-latitude sailing may be derived.

Traverse Tables.

A table in which the true difference of latitude and departure, corresponding to certain distances for every course, expressed in points and degrees, are laid down, is called a *traverse table*. It is very useful to enable the seaman to solve the several problems which occur in navigation by simple inspection. It must of course be calculated on some of the principles laid down in this chapter.

It is evident that as this table contains the relations of the sides and angles of a right-angled triangle, the solution of any right-angled triangle, whose sides represent any other quantities, will be given by it, by making the requisite changes.

Thus, the course remaining the same, if, for difference of latitude we look out in the table the meridional difference of latitude, the corresponding departure will be the difference of longitude; also, the difference of longitude can be found from the departure by these tables, by looking out the middle latitude as a course, and the departure as a true difference of latitude; then the corresponding distance is the difference of longitude.

SECT. II.—LONGITUDE AND LATITUDE.

PROB. I.—Given latitude from, and latitude in; to find the true difference of latitude.

Rule.—Under latitude in, with its proper name, i.e., N. or S., place latitude from. Subtract the greater from the less, if of the same name, and reduce to minutes. The result is the true difference of latitude required, and is of the same or different name with latitude in, according as latitude in is greater or less than latitude from. If they are of different names, add and affect with the name of latitude in.

Ex. 1.—A vessel sails from the Lizard, Lat. $49^{\circ} 58' \text{ N.}$, to Cape St Vincent, Lat. $37^{\circ} 3' \text{ N.}$; what is the true diff. of latitude?

$$\begin{aligned} \text{Latitude in} &= 37^{\circ} 3' \text{ N.} \\ \text{Latitude from} &= 49^{\circ} 58' \text{ N.} \end{aligned}$$

$$\text{True diff. latitude} = 12^{\circ} 55' \text{ S.} = 775 \text{ miles S.}$$

Ex. 2.—A vessel sails from New York, Lat. $40^{\circ} 42' \text{ N.}$, to Liverpool, Lat. $53^{\circ} 25' \text{ N.}$; find the true diff. of latitude.

$$\begin{aligned} \text{Latitude in} &= 53^{\circ} 25' \text{ N.} \\ \text{Latitude from} &= 40^{\circ} 42' \text{ N.} \end{aligned}$$

$$\text{True diff. latitude} = 12^{\circ} 43' \text{ N.} = 763 \text{ miles N.}$$

Ex. 3.—A ship sailed from Funchal, Lat. $32^{\circ} 38' \text{ N.}$, to the Cape of Good Hope, Lat. $34^{\circ} 29' \text{ S.}$; what is the true diff. of latitude?

$$\begin{aligned} \text{Latitude in} &= 34^{\circ} 29' \text{ S.} \\ \text{Latitude from} &= 32^{\circ} 38' \text{ N.} \end{aligned}$$

$$\text{True diff. latitude} = 67^{\circ} 7' \text{ S.} = 4027 \text{ miles S.}$$

PROB. 2.—Given the latitude from, and true difference of latitude; to find latitude in.

Rule.—If the latitude from and true difference be of the same name, add them (the true difference of latitude being turned, if necessary, into degrees and minutes); the sum is the latitude in of the same name. If of unlike names, under latitude from place the true difference of latitude, subtract the less from the greater; the result, with the name of the greater, is the latitude in.

Ex. 1.—A ship sailed from the Lizard, $49^{\circ} 58' \text{ N.}$, and made good, in a northerly direction, 207 miles; what is the latitude in?

$$\begin{aligned} \text{Latitude from} &= 49^{\circ} 58' \text{ N.} \\ \text{True diff. latitude} &= 3^{\circ} 27' \text{ N.} \end{aligned}$$

$$\text{Latitude in} = 53^{\circ} 25' \text{ N.}$$

Ex. 2.—A ship in Lat. $57^{\circ} 18' \text{ N.}$ sailed due S. 3759 miles; what is the latitude in?

$$\begin{aligned} \text{Latitude from} &= 57^{\circ} 18' \text{ N.} \\ \text{True diff. latitude} &= 63^{\circ} 9' \text{ S.} \end{aligned}$$

$$\text{Latitude in} = 8^{\circ} 51' \text{ S.}$$

Preliminary principles.

Preliminary principles.

PROB. 3.—To find the meridional difference of latitude; having given latitude from, and latitude in. Take the meridional parts for the two latitudes from the table for meridional parts; subtract if the names be alike, and add if the names be unlike. The result is the meridional difference of latitude, and is N. or S. according as the latitude in is N. or S. of latitude from.

Ex. 1.—Required the meridional diff. of latitude in sailing from Cape Finisterre, Lat. $42^{\circ} 52' N.$, to Port Praya, in the island of Santiago, Lat. $14^{\circ} 54' N.$

Latitude in.....	$14^{\circ} 54' N.$	Mer. parts.....	904 N.
Latitude from.....	$42^{\circ} 52' N.$	Mer. parts.....	2852 N.
		Mer. diff. lat....	1948 S.

Ex. 2.—To find the meridional diff. of latitude in sailing from Lat. $5^{\circ} 35' N.$ to $8^{\circ} 17' S.$

Latitude in.....	$8^{\circ} 17' S.$	Mer. parts.....	499 S.
Latitude from.....	$5^{\circ} 35' N.$	Mer. parts.....	335 N.
		Mer. diff. lat....	834 S.

PROB. 4.—To find the difference of longitude; having given longitude in, and longitude from.

Rule.—Under longitude in place longitude from; subtract, if of like name; reduce the result to minutes, and call it E. or W., according as longitude in is E. or W. of longitude from. Add, if of unlike names, and attach the name E. or W., according as the longitude in is E. or W. of longitude from. If the longitude found by this rule exceed 180° it must be subtracted from 360° , and affected with the contrary name.

Ex. 1.—A ship sails from Liverpool, Long. $2^{\circ} 59' W.$, to New York, Long. $73^{\circ} 59' W.$; required the diff. of longitude.

Longitude in.....	$73^{\circ} 59' W.$
Longitude from.....	$2^{\circ} 59' W.$
Diff. Longitude.....	$71^{\circ} 0' W.$ = 4260 miles W.

Ex. 2.—A ship sails from Maskelyne's Isles, in Long. $167^{\circ} 59' E.$, to Olinda, in Long. $35^{\circ} 54' W.$; find the diff. of longitude.

Longitude in.....	$35^{\circ} 54' W.$
Longitude from.....	$167^{\circ} 59' E.$
	$203^{\circ} 53' W.$
	$360^{\circ} 0'$
Diff. longitude.....	$156^{\circ} 7' E.$ = 9367 miles E.

PROB. 5.—To find the longitude in; having given longitude from, and difference of longitude.

Rule.—Under longitude from place difference of longitude. If of like names, add, and the result is the longitude in of the same name as the longitude from; if of unlike names, subtract the less from the greater. The result, with the name of the greater, is the longitude in.

Ex. 1.—A ship from Long. $9^{\circ} 54' E.$ sailed westerly till the difference of longitude was 1398 miles; what is the longitude in?

Longitude from.....	$9^{\circ} 54' E.$
Diff. longitude.....	$23^{\circ} 18' W.$
Longitude in.....	$13^{\circ} 24' W.$

Ex. 2.—The longitude sailed from is $25^{\circ} 9' W.$, and diff. of longitude $112^{\circ} 6' W.$; find longitude in.

Longitude from.....	$25^{\circ} 9' W.$
Diff. longitude.....	$18^{\circ} 46' W.$
Longitude in.....	$43^{\circ} 55' W.$

SECT. III.—OF MEASURING A SHIP'S RUN IN A GIVEN TIME.

The method commonly used at sea to find the distance sailed in a given time is by means of a log-line and half-minute glass. (A description of these is given under the articles LOG, and LOG-LINE, which see.)

The interval between two consecutive knots on the line—also technically called a *knot*—is supposed to be the same fraction of a nautical mile (6080 feet) that half a minute is

of an hour. Hence the proper length of a knot is $\frac{6080}{120}$ = 51 feet nearly. But although the line and glass be at any time perfectly adjusted to each other, yet as the line shrinks after being wet, and as the weather has a considerable effect on the glass, it will be necessary to examine them from time to time; and the distance given by them must be corrected accordingly. The distance sailed, therefore, may be affected by an error in the glass or in the line, or in both. The true distance may, however, be found as follows:—

PROB. 1.—The distance sailed by the log, and the seconds run by the glass, being given; to find the true distance run, the line being supposed right.

Let the number of seconds in which the glass runs out be n , and let d and d' be the true distance and distance by log respectively. Then evidently the longer the time the glass is running, the less is the distance by log compared with the true distance, and conversely. Hence we have the proportion—

$$d : d' :: 30'' : n'';$$

or true dist. : dist. by log :: $30''$: number of seconds the glass is running;

$$\text{or } d = \frac{d' \times 30}{n}.$$

Rule.—Multiply the distance given by log by 30, and divide by the number of seconds the glass is running; the result is the true distance run.

Ex. 1.—The hourly rate of sailing by the log is 9 knots, and the glass is found to run out in $35''$; required the true rate of sailing.

$$\begin{array}{r} 9 \\ 30 \\ \hline 35 \end{array} 270 (7 \cdot 7 = \text{true rate of sailing}.)$$

Ex. 2.—The distance sailed by the log is 73 miles, and the glass runs out in $26''$; required the true distance.

$$\begin{array}{r} 73 \\ 30 \\ \hline 26 \end{array} 2190 (84 \cdot 2 = \text{the true distance}.)$$

PROB. 2.—Given the distance sailed by the log, and the measured interval between two adjacent knots on the line; to find the true distance, the glass running exactly $30''$.

Here evidently the true distance is greater or less than the distance by log, as the measured interval is greater or less than 51 feet.

Let a be the measured interval between the knots in feet, and d and d' the true, and measure distances as before.

$$\text{Then } 51 : a :: d : d',$$

or 51 feet : measured distance in feet :: distance by log : true distance

$$\therefore \text{True distance} = \text{distance by log} + \frac{\text{measured distance} - 51}{51}$$

Rule.—Multiply the distance given by log by the measured length of a knot, and divide by 51; the quotient is the true distance.

Ex. 1.—The hourly rate of sailing by the log is 5 knots, and the interval between knot and knot measures 53 feet; required the true rate of sailing.

$$\begin{array}{r} 53 \\ 51 \\ \hline 51 \end{array} 265 (5 \cdot 19 = \text{true rate of sailing}.)$$

Ex. 2.—The distance sailed is 85 miles, by a log line which measures 42 feet to a knot; required the true distance run.

$$\begin{array}{r} 85 \\ 42 \\ \hline 170 \\ 51 \end{array} 3570 (70 = \text{true distance run}.)$$

PROB. 3.—Given the length of a knot, the number of seconds run by the glass in half a minute, and the distance

Preliminary principles.

sailed by the log. To find the true distance we must evidently compound the ratios given in problems 1 and 2 and we have

$$n \times 51 : 30 \times a :: d' : d;$$

$$\text{or } d = d' \times \frac{30a}{51n} = \frac{d' \cdot 10a}{17n}.$$

Rule.—Multiply the distance given by the log by 10 times the measured distance between the knots, and divide by 17 times the number of seconds the glass is running.

Ex.—The distance sailed by the log is 169 miles, the measured length of a knot is 42 feet, and the glass runs out in 33"; required the true distance.

Distance by the log.....	169
10 times length of a knot	420
	3180
17 times number of seconds	630
run by the glass	561)66780(119.037 = true distance.

SECT. IV.—ON COURSES AND CORRECTIONS OF COURSES.

Mariner's Compass.

A ship is enabled to keep her course at sea by means of an instrument called the mariner's compass. It consists of a magnetic steel bar attached to the under side of a card, divided into points and quarter points, and supported by a fine pin, on which it turns freely within a box covered with glass. By reason of the directive property of the magnet, the north point, which is commonly denoted by a *fleur de lis*, is readily known. The circumference of the card is generally divided into thirty-two points, which, in the best compasses, are again subdivided into half points and quarters. These are reckoned sufficient for nautical purposes. On the inside of the box is drawn a dark vertical line called lubber's point. This point, or rather line, and the pin on which the card turns, are in the same line or plane with the keel of the ship; and hence the point on the circumference of the card opposite to lubber's point shows the angle which the ship's course makes with the magnetic meridian, called the course of the ship.

The annexed diagram (fig. 5) gives a general view of

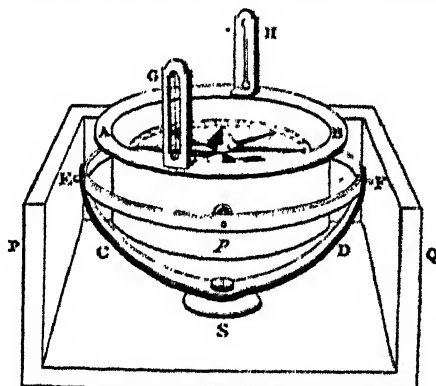

FIG. 5.

the compass. (For a full explanation of its magnetic properties, see MAGNETISM.) The names of the points, and the angles which they form with the meridian, are given in fig. 6, and as thus represented the instrument is called the steering compass.

The azimuth compass is the same instrument more nicely made. The circumference of the card is divided into degrees and parts by a vernier, and is fitted up with sight-vanes to take amplitudes and azimuths, for the purpose of determining the variation of the compass by observation. The variation is then applied to the magnetic course shown by the steering compass, whence the true course, with respect to the meridian, becomes known.

Besides the variation, the needle is also affected by the dip, which is likewise fully explained in the article MAGNETISM, as well as Mr Barlow's method of correcting the

Preliminary principles.

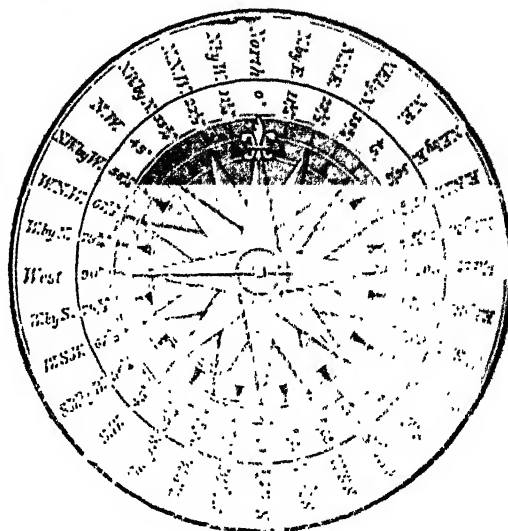

FIG. 6.

effects of local attraction, arising from the effects of the iron, guns, &c., in the vessel itself.

The compass course generally differs from the true course on account of three causes:—1. The variation of the compass; 2. The deviation of the compass; 3. The leeway. We shall now explain how these errors are to be applied.

1. *The Variation of the Compass.*—This is fully explained under the article MAGNETISM, which see. The mode of ascertaining its amount will be given hereafter.

PROB. I.—To find the true course, having given compass course.

Rule 1.—Allow easterly variation to the right, and allow westerly variation to the left.

Ex. 1. The compass course is W.N.W., and variation 3½ pts. W.; find the true course.

	Pts.	qrs.
Compass course	6	0 left of N.
Variation	3	1 left of N.
True course.....	9	1 left of N., or W. by S ¼ N.

Ex. 2.—The compass course is S.W. ¼ W., and variation 2½ E.; find the course.

	Pts.	qrs.
Compass course	4	3 right of S.
Variation	2	2 right of S.
True course.....	7	1 right of S., or W. by S ¼ W.

Ex. 3.—The compass course is N.W., the variation is 3½ E.; required the true course.

	Pts.	qrs.
Compass course.....	4	0 left of N.
Variation.....	3	1 right of N.
True course.....	0	3 left of N., or N ¼ W.

PROB. II.—Given the true course, to find the compass course.

Rule 2.—Allow easterly variation to the left, and westerly to the right.

Ex. 1.—The true course is N.N.E. ¼ E., and variation 1½ W.; find the compass course.

	Pts.	qrs.
True course	2	2 right of N.
Variation	1	2 right of N.
Compass course ...	4	0 right of N., or N.E.

Ex. 2.—The true course is N ¼ E., the variation 3½ E.; required the compass course.

Preliminary Principles.

	Pts.	qrs.
True course	0	3 right of N.
Variation	3	1 left of N.
Compass course	2	2 left of N., or N.N.W. $\frac{1}{2}$ W.

2. *The Deviation of the Compass.*—This error arises from the effects of local attraction, and varies with every different position of the ship's head. Several methods are employed in order to ascertain its amount. That most commonly adopted is to place a compass on shore, out of reach of the ship's attraction, and to take the bearing of the ship's compass, or some other object in the same direction with it; while at the same time the bearing of the compass on shore is taken on board. If now 180° be added to the bearing of the shore compass, so as to bring it round to the opposite point, the difference between this augmented bearing and the bearing at the ship's compass will be the amount of deviation for that position of the ship's head.

Suppose the ship's head is N., and that the reading off at the shore compass is S. 17° 15' W., and that the reading off at the ship's compass is N. 20° E. Adding 180° to the bearing of the shore compass, we get S. 197° 15' W., or N. 17° 15' E.; and subtracting this from the bearing of the ship's compass, N. 20° E., we get the deviation equal to 2° 45' E., when the ship's head is N. The ship is now turned round, so that the head points successively to every point of the compass, and the deviation for each position found as before.

A table is then made, showing the deviation for every point of the compass. The deviation so found is treated exactly as the *variation*,—i.e., in correcting the compass course to find the true course, easterly deviation is allowed to the right, and westerly deviation to the left; and conversely, to find the compass course from the true course, easterly deviation is allowed to the left, and westerly deviation to the right. Hence it appears, that when both variation and deviation are given, we may consider the latter as a correction of the former—to be added to it if of the same name, and to be subtracted from it if of the opposite name.

Ex. 1.—The compass course is S.W. $\frac{1}{4}$ W., variation 1 $\frac{1}{2}$ E., and deviation $\frac{1}{2}$ W.; what is the true course?

	Pts.	qrs.
Compass course	4	3 right of S.
Variation	1	3 right
Deviation	2	left
	1	1 right.
True course	6	0 right of S., or W.S.W.

Ex. 2.—The compass course is W. $\frac{1}{2}$ N., the variation 2 $\frac{1}{2}$ W., and deviation $\frac{1}{2}$ W.; what is the true course?

	Pts.	qrs.
Compass course	7	2 left of N.
Variation	2	2 left
Deviation	0	3 left
	3	1 left.
True course	10	3 left of N., or S.W. by W. $\frac{1}{4}$ W.

Ex. 3.—The true course is N.N.W. $\frac{1}{4}$ W., variation 1 $\frac{1}{2}$ E., and deviation $\frac{1}{2}$ W.; required the compass course.

	Pts.	qrs.
True course	2	3 left of N.
Variation	1	3 left.
Deviation	0	1 right.
	1	2 left.
Compass course	4	1 left of N., or N.W. $\frac{1}{4}$ W.

The following table is taken from the monthly examination-papers at the Royal Naval College, Portsmouth, and will serve as a specimen of the tables which ought to be made for all ships:—

Deviation of the Compass of H.M.S. Vesuvius for different positions of the Ship's Head.

Preliminary Principles.

Direction of Ship's Head.	Deviation of Compass.	Direction of Ship's Head.	Deviation of Compass.
N.	2° 45' E.	S.	3° 0' W.
N. by E.	4 57	S. by W.	4 20
N.N.E.	7 30	S.S.W.	5 0
N.E. by N.	9 0	S.W. by S.	6 7
N.E.	10 0	S.W.	7 0
N.E. by E.	10 55	S.W. by W.	7 27
E.N.E.	10 40	W.S.W.	7 50
E. by N.	9 55	W. by S.	8 20
E.	8 50	W.	8 50
E. by S.	7 15	W. by N.	8 10
E.S.E.	5 35	W.N.W.	6 50
S.E. by E.	3 40	N.W. by W.	5 40
S.E.	1 50	N.W.	4 50
S.E. by S.	0 20 E.	N.W. by N.	3 20
S.S.E.	0 56 W.	N.N.W.	1 40 W.
S. by E.	2 20	N. by W.	1 10 E.

3. *Leeway.*—The effect of the action of the wind upon the sails and hull of a ship is sometimes to produce a motion of the ship in a direction at right angles to that of the head or apparent course, as well as in this latter direction. The true course, therefore, is not that given by the compass, but that which is due to the composition of the two velocities of the ship,—viz., that in the direction of its head, and that at right angles to this direction. To obtain the true course from the compass course, therefore, we must add or subtract the angle of leeway, which is the angle between the compass course and the true course.

If the wind be on the right of a person on board ship who is looking towards the head, the real course is then evidently to the *left* of the direction of the ship's head,—i.e., of the apparent course. If the wind be on his left hand, the true course is to the right. In the former case the ship is said to be on the *starboard tack*, and in the latter on the *port tack*. Whence is derived the rule for obtaining the true course from the compass course.

Rule.—If the ship is on the starboard tack, allow leeway to the left; if on the port tack, allow leeway to the right. Conversely, to obtain the compass course from the true course on the starboard tack, allow leeway to the right; if on the port tack, allow it to the left.

There are many circumstances which prevent laying down accurate rules for the allowance of leeway. The construction of different vessels, their trim with regard to the nature and quantity of cargo, the position and area of sail set, the velocity of the ship and the swell of the sea, are all susceptible of great variation, and very much affect the leeway.

The following rules are usually given for the purpose:—

1. When a ship is close-hauled under all sail, the water smooth, and with a light breeze, *allow no leeway.*
2. When the top-gallant sails are handed, *allow one point.*
3. Under close-reefed topsails *allow two points.*
4. When one topsail is handed, *allow two points and a half.*
5. When both topsails are handed, *allow three points.*
6. When the fore-course is handed, *allow four points.*
7. When under mainsail only, *allow five points.*
8. Under balanced mizen, *allow six points.*
9. Under bare poles, *allow seven points.*

These rules, however, are not much to be depended upon. A very good method of estimating the leeway is to observe the bearing of the ship's wake as frequently as may be judged necessary, which may be conveniently enough done by drawing a small semicircle on the taffarel, with its diameter at right angles to the ship's length, and dividing its circumference into points and quarters. The angle contained between the semi-diameter which points right aft,

Plane
Sailing.

and that which points in the direction of the wake, is the leeway. But the best and most rational way of finding the leeway is to have a compass or semicircle on the taffarel, as before described, with a low crutch or swivel in its centre; after heaving the log, the line may be slipped into the crutch just before it is drawn in, and the angle it makes on the limb with the line drawn right aft, will show the leeway very accurately.

Ex. 1.—A ship's apparent course is S.S.W. $\frac{1}{2}$ W., leeway $2\frac{1}{2}$ points, the wind being S.E. $\frac{1}{2}$ E.; required the true course. In this case the wind is on the left of the vessel, or it is on the port tack, and leeway must be allowed to the right.

	Pts.	qrs.
Apparent course.....	2	3 right of S.
Leeway	2	2 right of S.
True course.....	5	1 right of S., or S.W. by W. $\frac{1}{2}$ W.

Ex. 2.—The apparent course is N.N.W., leeway $1\frac{1}{2}$ points, and wind E.N.E. Here the vessel is on the starboard tack.

	Pts.	qrs.
Apparent course.....	2	0 left of N.
Leeway	1	2 left of N.
True course.....	3	2 left of N., or N.W. by N. $\frac{1}{2}$ W.

Ex. 3.—The true course of a ship is S.E. $\frac{1}{2}$ S., leeway $2\frac{1}{2}$ points, and wind N.N.E.; required the compass course. Here the ship is on the port tack.

	Pts.	qrs.
True course	3	2 left of S.
Leeway	2	2 right of S.
Compass course.....	1	0 left of S., or S. by E.

CHAP. II.—ON PLANE SAILING.

Plane sailing is the art of navigating a ship upon principles deduced from the notion of the earth's being an extended plane. On this supposition, the meridians are considered parallel lines. The parallels of latitude are at right angles to the meridians; the lengths of the degrees on the meridians, equator, and parallels of latitude are everywhere equal; and the degrees of longitude are reckoned on the parallels of latitude as well as on the equator; and consequently the departure and difference of longitude are equal. In fact, in the right-angled triangle ABC (fig. 7), where AB is the true difference of latitude, BC the course, AC the distance, and AB the departure, which is assumed equal to the difference of longitude; all the problems in sailing are solved by the relations of the sides and angles of the single right-angled triangle ABC. Except, however, for a small portion of the earth's surface near the equator, the departure cannot be assumed equal to the difference of longitude without very considerable error; and the longitude in cannot be at all depended on when found by this method. If, however, the departure be an element, this method is correct.

In fig. 7, A is the place from which the ship sails; AB the meridian, and equal to the true difference of latitude; BC perpendicular to the meridian, and equal to the departure. It is always possible and easy to construct a right-angled triangle when two parts, of which one is a side, beside the right angle, are given. Consequently problems in navigation may always be solved by construction, with the aid of the rule and compasses. In making constructions for this purpose, it is only necessary to attend to the following convention:—Let the upper part of the paper or plan on which the drawing is to be made represent the *north*; then the lower part will be *south*, the right-hand side *east*, and the

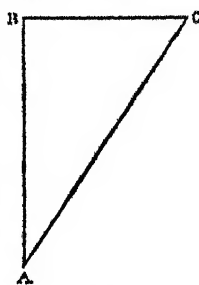

Fig. 7.

left-hand side *west*. This convention we have already tacitly assumed in treating of the corrections of the courses.

Plane
Sailing.

To make a Construction.

A north and south line is to be drawn, to represent the meridian of the place *from* which the ship sailed; and the upper or lower end of this line is to be marked as the position of the place, according as the course is southerly or northerly. From this point as centre, with the chord of 60° (on the rule), an arc of a circle is to be described from the meridian, towards the right or left, according as the course is easterly or westerly; and the course, taken from the line of chords if given in degrees, but from the line of rhumbs if expressed in points of the compass, is to be laid on this arc, beginning from the meridian. A straight line drawn through this point and the point sailed from is the direction of the distance, which, if given, must be laid down on this line, beginning at the point sailed from. A straight line is to be drawn from the extremity of the distance perpendicular to the meridian; and hence the true difference of latitude and the departure will be found.

If the true difference of latitude be given, it is to be laid down on the meridian, beginning at the point from which the ship sailed; and a straight line drawn through the extremity of the difference of latitude, perpendicular to the meridian, to meet the distance laid down, will limit the figure, and enable us to find the parts required.

If the departure be given, it is to be laid off on a parallel, and the line drawn through its extremity will limit the distance.

If the distance and true difference of latitude be given, through the extremity of the true difference of latitude draw a straight line perpendicular to the meridian; extend a pair of compasses to the given distance, place one of its points at the place from which the ship sailed, and let the other point be in the perpendicular line first drawn; join this point with the point *from*, and the triangle is determined, and the course and departure found.

If the departure and distance are given, with the point *from* as centre and the distance as radius, describe an arc of a circle. Let the departure be laid off on a parallel, so that one point is in the meridian and the other in the circle just described. Join this latter point with the point *from*, and the triangle is formed. The general mode of solving problems in plane sailing has already been given in chap. i, sect. 2. The following examples will show how the formulæ are to be applied:—

Obs. It is to be distinctly understood that the above method cannot be applied to obtain the difference of longitude without very sensible error.

Ex. 1.—A ship from St Helena, in Lat. $15^\circ 55'$ S. sailed S.W. by S. 158 miles; required the latitude in, and departure.

By Construction.—Draw the meridian AB (fig. 8), and with the chord of 60° describe the arc mn, and make it equal to the rhumb of three points; and through A draw AC equal to 158 miles; from C draw CB perpendicular to AB; then AB applied to the scale from which AC was taken will be found to measure 131.4, and BC 87.8.

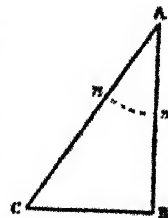

Fig. 8.

By Calculation.—To find the true difference of latitude.

Log. cosine of course.....	3 pts.	= 9.91935
Log. distance	158 m.	= 2.19866
		- 10

Log. true diff. lat.....	= 2.11851
Hence, true diff. lat.....	= 131.4 S.

To find departure.

Log. sin course	3 pts.	= 9.74474

---------------------	------	-----------

Plane
Sailing.

By Inspection.—In the traverse table, the difference of latitude answering to the course 3 points, and distance 158 miles, in a distance column, is 131.4, and departure 87.8.

By Gunter's Scale.—The extent from 8 points to 5 points, the complement of the course on the line of sine rhumbs (marked S. R.) will reach from the distance 158 to 131.4, the difference of latitude on the line of numbers; and the extent from 8 points to 3 points on sine rhumbs will reach from 158 to 87.8, the departure on numbers.¹

Latitude St Helena.....	15° 55' S.
Diff. latitude	2 11 S.
Latitude in.....	18 6 S.

Ex. 2.—A ship from St George's, in Lat. 38° 45' N., sailed S.E.½S., and the latitude by observation was 35° 7' N.; required the distance run, and departure.

Latitude St George's	38° 45' N.
Latitude in	35 7 N.
Diff. latitude.....	3 38=218 miles S.

By Construction.—Draw the portion of the meridian AB (fig. 9) equal to 218 miles; from the centre A, with the chord of 60°, describe the arc mn, which make equal to the rhumb of 3½ points; through A draw the line AC, and from B draw BC perpendicular to AB, and let it be produced till it meets AC in C. Then the distance AC being applied to the scale will measure 282 miles, and the departure BC 179 miles.

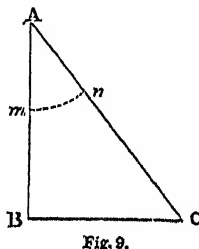

Fig. 9.

By Calculation.—To find the distance.

L sec of the course	3½ pts. = 10.11181
Log. true diff. latitude	218 m. = 2.33846
	-10
Log. distance	= 2.45027
Or distance	= 282

To find departure.

L tan of the course	3½ pts. = 9.91417
Log. true diff. latitude	218 m. = 2.33846
	-10
Log. departure	= 2.25263
Or departure	= 178.9

By Inspection.—Find the given difference of latitude 218 miles in latitude column, under the course of 3½ points; opposite to which, in distance column, is 282 miles; in departure column 178.9 m.; the distance and departure required.

By Gunter's Scale.—Extend the compass from 4½ points, the complement of the course, to 8 points on sine rhumbs; that extent will reach from the difference of latitude 218 miles to the distance 282 miles on numbers; and the extent from 4 points to the course 3½ points on the line of tangent rhumbs (marked T. R.) will reach from 218 miles to 178.9, the departure on numbers.

Ex. 3.—A ship from Palma, in Lat. 28° 37' N., sailed N.W. by W., and made 192 miles of departure; required the distance run, and the latitude come to.

By Construction.—Make the departure BC (fig. 10) equal to 192 miles, draw BA perpendicular to BC, and from the centre C, with the chord of 60°, describe the arc mn, which make equal to the rhumb of 3 points, the complement of the course; draw a line through Cn, which produce till it meet BA in A. Then the distance AC being measured, will be equal to 230.9, and the difference of latitude AB will be 128.3 miles.

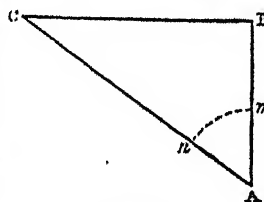

Fig. 10

By Calculation.—To find the distance.

L cos of course	5 pts. = 10.08015
Log. departure	192 m. = 2.28330
	-10
Log. distance.....	230.9 = 2.36345

To find the true difference of latitude.

L cot of course.....	5 pts = 9.82489
Log. departure.....	192 m. = 2.28330
	-10
Log. true diff. latitude	128.3 = 2.10819

By Inspection.—Find the departure 192 miles in its proper column above the given course 5 points; and opposite thereto is the distance 231 miles, and difference of latitude 128.3, in their respective columns.

By Gunter's Scale.—The extent from 5 points to 8 points on the line of sine rhumbs, being laid from the departure 192 on numbers, will reach to the distance 231 on the same line; and the extent from 5 points to 4 points on the line of tangent rhumbs will reach from the departure 192, to the difference of latitude 128.3 on numbers.

Latitude of Palma	28° 37' N.
Diff. latitude.....	2 8 N.
Latitude in	30 45 N.

Ex. 4.—A ship from a place in Lat. 43° 13' N., sails between the north and east 285 miles, and is then by observation found to be in Lat. 46° 31' N.; required the course and departure.

Latitude sailed from	43° 13' N.
Latitude by observation.....	46 31 N.
Diff. of latitude.....	3 18=198 miles.

By Construction.—Draw the portion of the meridian AB (fig. 11) equal to 198 miles; from B draw BC perpendicular to AB; then take the distance 285 miles from the scale, and with one foot of the compass in A describe an arc intersecting BC in C, and join AC. With the chord of 60° describe the arc mn, the portion of which contained between the distance and difference of latitude, applied to the line of chords, will measure 46°, the course; and the departure BC being measured on the line of equal parts, will be found equal to 205 miles.

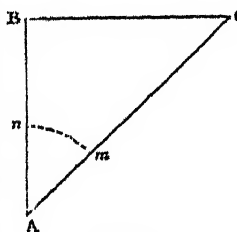

Fig. 11.

By Calculation.—To find the course.

Log. true diff. latitude	(198) + 10 = 12.29660
Log. distance.....	285 = 2.45484
	-
L cos course	46° = 9.84176
Or course is.....	N. 46° 0' E.

To find the departure.

L sin course	46° = 9.85693
Log. distance.....	285 = 2.45484
	-10
Log. departure	205 = 2.31177

By Inspection.—Find the given distance in the table in its proper column; and if the difference of latitude answering thereto is the same as that given, namely, 198, then the departure will be found in its proper column, and the course at the top or bottom of the page, according as the difference of latitude is found in a column marked lat. at top or bottom. If the difference of latitude thus found does not agree with that given, turn over till the nearest thereto is found to answer to the given distance. This is in the page marked 46 degrees at the bottom, which is the course, and the corresponding departure is 205 miles.

By Gunter's Scale.—The extent from the distance 285 to the difference of latitude 198 on numbers, will reach from 90° to 44°, the complement of the course on sines; and the extent from 90° to the course 46° on the line of sines being laid from the distance 285, will reach to the departure 205 on the line of numbers.

Ex. 5.—A ship from Fort-Royal, in the island of Grenada, in Lat. 12° 9' N., sailed 260 miles between the south and west, and made 190 miles of departure; required the course and latitude come to.

¹ For the method of resolving the various problems in navigation by the Sliding Gunter, the reader is referred to Dr Mackay's Treatise on the Description and Use of that instrument.

Plane
Sailing.

By Construction.—Draw BC perpendicular to AB, and equal to the given departure 190 miles; then from the centre C, with the distance 260 miles, sweep an arc intersecting AB in A, and join AC. Now describe an arc from the centre A with the chord of 60°, and the portion *mn* of this arc, contained between the distance and difference of latitude, measured on the line of chords, will be 47°, the course; and the difference of latitude AB, applied to the scale of equal parts, measures 177½ miles.

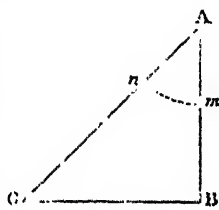

Fig. 12.

By Calculation.—To find the course.

Log. departure.....	190 + 10 =	12-27875
Log. distance.....	260 =	2-41497
L sin course.....	46° 57' =	9-86378
Or course is.....		S. 46° 57' W.

To find the true difference of latitude.

L cos course.....	46° 57' =	9-83419
Log. distance.....	260 =	2-41497
		-10
Log. true diff. latitude.....	177.3 =	2-24916

By Inspection.—Seek in the traverse table until the nearest to the given departure is found in the same line with the given distance 260. This is found to be in the page marked 47° at the bottom, which is the course; and the corresponding difference of latitude is 177.3.

By Gunter's Scale.—The extent of the compass, from the distance 260 to the departure 190 on the line of numbers, will reach from 90° to 47°, the course on the line of sines; and the extent from 90° to 43°, the complement of the course on sines, will reach from the distance 260 to the difference of latitude 177½ on the line of numbers.

Latitude Fort-Royal.....	12° 9' N.
Difference of latitude.....	177 = 2 57 S.
Latitude in.....	9 12 N.

Ex. 6.—A ship from a port in Lat. 7° 56' S. sailed between the south and east till her departure was 132 miles, and was then, by observation, found to be in Lat. 12° 3' S.; required the course and distance.

Latitude sailed from.....	7° 56' S.
Latitude in, by observation.....	12 3 S.
Difference of latitude.....	4 7 = 247

By Construction.—Draw the portion of the meridian AB equal to the difference of latitude 247 miles; from B draw BC perpendicular to AB, and equal to the given departure 132 miles, and join AC; then with the chord of 60° describe an arc from the centre A; and the portion *mn* of this arc, being applied to the line of chords, will measure about 28°, and the distance AC, measured on the line of equal parts, will be 280 miles.

Fig. 13.

By Calculation.—To find the course.

Log. departure.....	132 + 10 =	12-12057
Log. true diff. latitude.....	247 =	2-39270
L tan course.....	28° 7' =	9-72787
Or course is.....		S. 28° 7' E.

To find the distance.

L sec course.....	28° 7' =	10-05451
Log. true diff. latitude.....	247 =	2-39270
		-10
Log. distance.....	280 =	2-44724

By Inspection.—Seek in the table till the given difference of latitude and departure, or the nearest thereto, are found together in their respective columns, which will be under 28°, the required course; and the distance answering thereto is 280 miles.

By Gunter's Scale.—The extent from the given difference of latitude 247 to the departure 132 on the line of numbers, will reach from 45° to 28°, the course on the line of tangents; and the extent from 62°, the complement of the course, to 90° on the sines, will reach from the difference of latitude 247 to the distance 280 on numbers.

The six problems whose solutions are illustrated above

are all that occur in the solution of the right-angled triangle, whose sides represent the true difference of latitude, departure, and distance, and one of whose angles is the course.

Mercator's
Sailing.

CHAP. III.—ON MERCATOR'S SAILING.

We have already explained the principle of Mercator's Chart, and have shown that in every problem of navigation there is a second right-angled triangle similar to that whose solutions formed the subject of investigation in chapter ii.; and the sides of which, corresponding to the true difference of latitude and departure, are the meridional difference of latitude and difference of longitude.

We have already given a rule for finding the meridional parts for any given latitude, on the supposition that the earth is a perfect sphere. If the earth's oblateness be taken into account, and the compression, *i.e.*, the ratio of the difference of the equatorial and polar semi-diameters to the equatorial semi-diameter, be taken as $\frac{1}{298}$, which it is very nearly, the meridional parts for latitude *l* will be given by the formula—

$$\text{Mer. parts} = 7915.705 \log. \tan. \left(45^\circ + \frac{l}{2} \right) - 22.88 \sin l - 0.0508 \sin 3l - \&c.$$

Let AD (fig. 14) be the meridian, BAC the course, AB the true difference of latitude, AD the meridional difference of latitude; then

DE is the diff. long., and
ED = DA × tan BAC; or,
diff. long. = mer. diff. lat. × tan course;
or log. diff. long. = log. mer. diff. lat. +
L tan course - 10.

Also, by similar triangles, ADE and ABC, we have

$$\begin{aligned} DE : BC :: DA : BA, \text{ or, } & \\ DE = BC \times DA & \\ BA & \end{aligned}$$

$$\therefore \text{diff. long.} = \text{dep.} \times \text{mer. diff. lat.} \div \text{true diff. lat.}; \text{ or,}$$

$$\log. \text{diff. long.} = \log. \text{dep.} + \log. \text{mer. diff. lat.} - \log. \text{true diff. lat.}$$

Whence, from the departure and true and meridional differences of latitude, the difference of longitude may be found. The following examples will illustrate the mode of using these formulæ:—

Ex. 1. A ship sails from Cape Finisterre, Lat. 42° 52' N., Long. 9° 17' W., to Port Praya, in the island of Santiago, Lat. 14° 54' N., and Long. 23° 29' W.; required the course and distance.

Lat. from.....	42° 52' N.	Mer. parts... 2452
Lat. in.....	14 54 N.	Mer. parts... 904
Diff. of lat.....	27 58 S.	Mer. diff. lat. 1948 S.
		1078 S.
Long. from.....	9° 17' W.	
Long. in.....	23 29 W.	
Diff. long.....	14 12 =	852 W.

By Construction.—Draw the straight line AD (fig. 15), to represent the meridian of Cape Finisterre, upon which lay off AB, AD, equal to 1078 and 1948, the true and meridional differences of latitude. From D draw DE perpendicular to AD, and equal to the difference of longitude 852; join AE, and draw BC parallel to DE; then the distance AC will measure 1831 miles, and the course BAC 23° 37'.

Fig. 14.

By Calculation.—To find the course.

Log. diff. long.....	852 + 10 =	12-93044
Log. mer. diff. lat.....	1948 =	3-28939
L tan course.....	23° 37' =	9-44086
Or course is.....		S. 23° 37' W.

Ex. 2.—A ship from Cape Henlopen in Virginia, in Lat. 38° 47' N., Long. 75° 4' W., sailed 267 miles N.E. by N.; required the ship's present place.

By Construction.—With the course, and distance sailed, construct the triangle ABC (fig. 16), and the difference of latitude AB being measured, is 222 miles; hence the latitude in is 42° 29' N., and the meridional difference of latitude 293. Make AD equal to 293, and draw DE perpendicular to AD, and meeting AC produced in E; then the difference of longitude DE being applied to the scale of equal parts, will measure 196; longitude in is therefore 71° 48' W.

CHAP. IV.—ON TRAVERSE SAILING, OR COMPOUND COURSES.

It is the first business of the navigator, when he is about to conduct a ship from one port to another, to calculate beforehand the course on which the vessel is to be steered, and the distance she must run on that course. If the sea is perfectly free from obstruction between the two ports, one course and one distance will suffice for this purpose. It very seldom happens, however, that the sea is free from obstruction; but rocks or shoals, islands or some part or a mainland, intervenes, and a change of course is thus rendered necessary. In this case, the course and distance or the vessel, supposing the navigation unobstructed, having been taken from the chart, the mariner will determine how many changes of course are necessary, and will proceed to calculate the several courses and distances which shall be equivalent to the one course and distance on which the vessel would sail if unobstructed. This calculation, it must be remarked, is very different from that of the course and distance actually made good on a given day, when, by reason of variation of winds and other causes, the course requires to be altered; although naturally the modes of making these calculations are similar. In the former case, however, the distances to be dealt with are very much greater, and the changes of course less frequent, than in the latter.

The investigations of this chapter are intended to guide the navigator in making his preliminary calculation; the mode of correcting the course and calculating the distance run in each day will form the subject of a subsequent investigation.

If a ship sail on two or more courses in a given time, the irregular track she describes is called a traverse; and to resolve a traverse is the method of reducing these several courses and distances run into a single course and distance.

RULE 1.—Make a table sufficiently large to contain the several courses, &c. Divide this table into six columns; the courses are to be put in the first, and the corresponding distances in the second column; the third and fourth columns are to contain the differences of latitude, and the two last the departures.

NAVIGATION.

Traverse
Sailing, or
Compound
Courses.

The several courses and their corresponding distances being properly arranged in the table, find the true difference of latitude and departure answering to each in the traverse table, remembering that the true difference of latitude is to be put into a N. or S. column according as the course is in a northern or southern direction, and that the departure is to be put in E. or W. column according as the course is easterly or westerly. Add together these several quantities in each of the columns, and set the sum down at the bottom. The difference between the sums in the N. and S. columns will be the true difference of latitude made good, of the same name with the greater; and the difference between the sums of the E. and W. columns is the departure made good, of the same name with the greater sum.

Look in the traverse table for a true difference of latitude and departure agreeing as nearly as possible with those above; then the distance will be found on the same line, and the course at the top or bottom of the page, according as the true difference of latitude is greater or less than the departure, since in the former case the course is less than 45° or 4 points, and in the latter case greater.

Having found the latitude, find also the meridional difference of latitude; and to the course and meridional difference of latitude in a latitude column, the corresponding departure will be the difference of longitude, which, applied to the longitude from, will give the longitude in.

It is also easy to resolve a traverse by construction; and we now show how this may be done, although it is scarcely ever practised at sea.

Describe a circle with the chord of 60° as radius, and in it draw two diameters at right angles to each other, at whose extremities are to be marked the initials of the cardinal points, N. being uppermost.

Lay off each course on the circumference, reckoned from its proper meridian; and from the centre to each point draw lines, which are to be marked with the proper number of the course.

On the first radius lay off the first distance from the centre, and through its extremity, and parallel to the second radius, draw the second distance of its proper length; through the extremity of the second distance, and parallel to the third radius, draw the third distance of the proper length; and so on until all the distances are drawn.

A line drawn from the extremity of the last distance to the centre of the circle will represent the distance made good; and a line drawn from the same point perpendicular to the meridian, produced if necessary, will represent the departure; and the portion of the meridian intercepted between the centre and departure will be the difference of latitude made good.

To construct for the difference of longitude we must find by the table the meridional difference of latitude, and lay it off on the meridian, and then complete the triangle similar to that whose sides represent the true difference of latitude; distance and departure as usual.

Ex. 1.—A ship from Fayal, in Lat. $38^\circ 32' N.$, and Long. $28^\circ 36' W.$, sailed as follows:—E.S.E., 163 miles; S.W. $\frac{1}{2}$ W., 110 miles; S.E. $\frac{1}{2}$ S., 180 miles; and N. by E. 68 miles: required the latitude and longitude in, the course, and distance made good.

Course.	Dist.	Diff. of Lat.		Departure.	
		N.	S.	E.	W.
E.S.E.	163	...	62.4	150.6	...
S.W. $\frac{1}{2}$ W.	110	...	69.8	...	85.0
S.E. $\frac{1}{2}$ E.	180	...	144.5	107.2	...
N. by E.	68	66.7	...	13.3	...
		66.7	176.7	271.1	85.0
			66.7	85.0	
S. $41\frac{1}{2}^\circ$ E.	281		210.0	186.1	

Latitude from $38^\circ 32' N.$ Mer. parts..... 2509
True diff. latitude..... $3^\circ 30' S.$
Latitude in $35^\circ 2' N.$ Mer. parts..... 2247
Mer. diff. lat... 262

Now to course $41\frac{1}{2}^\circ$, and opposite 131, half the meridional difference of latitude in latitude column, stands 115 in a departure column, which doubled gives 230 for difference of longitude.

Longitude from..... $28^\circ 36' W.$
Diff. longitude $3^\circ 50' E.$
Longitude in..... $24^\circ 46' W.$

By Construction.—With chord of 60° describe the circle NESW (fig. 23), the centre of which represents the place the ship sailed from. Draw two diameters NS, EW, at right angles to each other, the one representing the meridian, and the other the parallel of latitude of the place sailed from. Take each course from the line of rhumbs, lay it off on the W

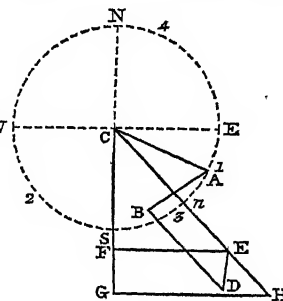

FIG. 23.

and draw DE parallel to C4, and equal to 68 miles. Now CE being joined, will represent the distance made good, which, applied to the scale, will measure 281 miles. The arc Sn, which represents the course, being measured on the line of chords, will be found equal to $41\frac{1}{2}^\circ$. From E draw EF perpendicular to CS produced; then CF will be the difference of latitude, and FE the departure made good, which, applied to the scale, will be found to measure 210 and 186 miles respectively. On CF produced lay off to the scale CG equal to 262, the meridional difference of latitude; and through G draw GH parallel to FE, meeting CE produced in H. Then GH is the difference of longitude; and, when applied to the scale, will be found to measure 230 miles.

Although the above method is that usually employed at sea to find the difference of longitude, yet, as it has been already observed, it is not to be depended on, especially in high latitudes, long distances, and a considerable variation in the courses; in which case the following method becomes necessary:—

RULE 2.—Complete the traverse table as before, to which annex five columns. Now, with the latitude from, and the several differences of latitude, find the successive latitudes, which are to be placed in the first of the annexed columns; in the second, the meridional parts corresponding to each latitude are to be put; and in the third, the meridional differences of latitude.

Then to each course, and corresponding meridional difference of latitude, find the difference of longitude by *Ex. 4*, chap. iii., which place in the fourth or fifth columns, according as the course is easterly or westerly; and the difference between the sums of these columns will be the difference of longitude made good upon the whole, of the same name with the greater.

Remarks.

1. When the course is north or south, there is no difference of longitude.
2. When the course is east or west, the difference of longitude cannot be found by Mercator's Sailing; in this case the following rule is to be used:—

To the nearest degree to the given latitude taken as a course, find the distance answering to the departure in a latitude column; this distance will be the difference of longitude.

Ex. 2.—A ship from Lat. $78^\circ 15' N.$, Long. $28^\circ 14' E.$, sailed the following courses and distances, viz.:—W.N.W. 154 miles, S.W. 96, N.W. $\frac{1}{2}$ W. 89, N. by E. 110, N.W. $\frac{1}{2}$ N. 56, S. by E. $\frac{1}{2}$ E. 78. The latitude in is required, and the longitude, by both methods; the bearing and distance of Hacluit's headland, in Lat. $79^\circ 55' N.$, Long. $11^\circ 55' E.$, is also required.

S. by E.¾E.....	78	...	73.4	26.3	...	81 35	8970	294	...	218.0
						80 22	8504	466	166.7	...
		268.2	141.3	47.8	312.4				290.3	1639.3
		141.3			47.8					290.3
		126.9			264.6					1349.0

By Rule I.					
Lat. from	78° 15' N.	Mer. parts.....	7817		
Diff. lat.	2 7 N.				
Lat. in.....	80 22 N.	Mer. parts.....	8504		
Mer. diff. lat.			687		
Log. mer. diff. lat.		687	= 2.83696		
Log. dep.		264.6	= 2.42256		
			5.25952		
Log. true diff. lat.		126.2	= 2.10346		
Log. diff. long.		143.2	= 3.15608		
		23° 52' W.			
Long. from	28 14 E.				
Long. in.....	4 22 E.				

The error of this method, in above example, is therefore 1° 23'.

Long. from 28° 14' E.
 Diff. long. 22 29 W.
 Long. in..... 5 45 E.

To find the bearing and distance of Hacluit's headland—

Lat. H. H. = 79° 55' N. M. P. 8347 Long. 11° 55' E.
 Lat. ship = 80 22 N. M. P. 8504 Long. 5 45 E.
 Diff. lat. = 0 27 S. M. D. L. 157 Diff. long. 6 10 E.
 370

Now, opposite to 78.5, half the meridional difference of latitude, and 185.0, half the difference of longitude, stands the course 67°; and opposite to the difference of latitude 27, the distance is 69 miles. Hence Hacluit's headland bears S. 67° E., distant 69 miles.

CHAP. V.—OF PARALLEL SAILING.

When the course is 8 points or 90° from the meridian, —i.e., due E. or W.,—the true difference of latitude becomes = 0, and the rules we have investigated in chaps. iii. and iv. fail to give any result. In this case the ship sails on a parallel of latitude. We have already proved in chap. i., that, neglecting the earth's oblateness, the arc of a parallel, in any given latitude, intercepted between two meridians, is equal to the corresponding arc of the equator, in other words, the difference of longitude, multiplied by the cosine of the latitude.

Whence we derive these three formulæ for parallel sailing:—

$$\begin{aligned} \text{Distance} &= \text{diff. longitude} \times \cos \text{latitude}; \\ \cos \text{latitude} &= \frac{\text{distance}}{\text{diff. longitude}}; \\ \text{Diff. longitude} &= \frac{\text{distance}}{\cos \text{latitude}}. \end{aligned}$$

Problems in parallel sailing may be solved by construction; for it is evident that we have only to construct a right-angled triangle whose hypotenuse is the difference of longitude, one of the sides the distance, and the angle between this side and the hypotenuse the latitude. Also it is evident, that in a traverse table, if we consider the latitude a course, and the difference of longitude a distance, the distance will be a true difference of latitude.

Ex. 1.—Required the number of miles contained in a degree of longitude in latitude 55° 58'.

By Construction.—Draw the indefinite right line AB (fig. 24); make the angle BAC equal to the given latitude 55° 58', and AC equal to the number of miles contained in a degree of longitude at the equator, namely, 60; from C draw CB perpendicular to AB; and AB being measured on the line of equal parts, will be found equal to 33.5, the miles required.

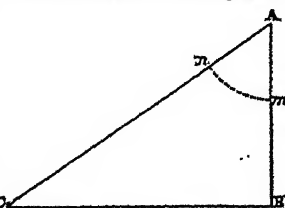

Fig. 24.

By calculation.—

$$\begin{aligned} L \cos \text{lat.} &= 55^\circ 58' = 9.7479360 \\ \text{Log. miles in a degree} &= 60 = 1.7781513 \\ &= 10 \\ \text{Log. miles in a deg. in lat. } 55^\circ 58' &= 1.5260873 \end{aligned}$$

By Inspection.—To 56°, the nearest degree to the given latitude, and distance 60 miles, the corresponding difference of latitude is 33.6, which is the miles required.

By Gunter's Scale.—The extent from 90° to 34°, the complement of the given latitude on the line of sines, will reach from 60 to 33.6 on the line of numbers.

There are two lines on the other side of the scale, with respect to Gunter's line, adapted to this particular purpose, one of which is entitled *chords*, and contains the several degrees of latitude; the other, marked M. L., signifying *miles of longitude*, is the *line of longitudes*, and shows the number of miles in a degree of longitude in each parallel. The use of these lines is therefore obvious.

Ex. 2.—Required the compass course and distance from A to B.

Given lat. A = 17° 30' S. Long. A = 9° 12' E.
 lat. B = 17 30 S. Long. B = 10 42 E.

Variation 1½ E., and deviation as in the table on p. 13.
 The true course is due E.

$$\begin{aligned} \text{Also, long. A} &= 19^\circ 12' \text{ E.} \\ \text{long. B} &= 10 42 \text{ E.} \\ \text{Diff. long.} &= 1 30 = 90 \text{ E.} \end{aligned}$$

$$\begin{aligned} \text{Log. diff. long.} &= 90 = 1.954243 \\ L \cos \text{lat.} &= 17^\circ 30' = 9.979419 \\ &= 10 \\ \text{Log. dist.} &= 85.8 \text{ m.} = 1.933662 \end{aligned}$$

Ex. 4.—A ship from Cape Finisterre, Lat. $42^{\circ} 52' N.$, Long. $9^{\circ} 17' W.$, sailed due W. 342 miles; required the longitude in.

By Construction.—Draw the straight line AB (fig. 25), equal to the given distance 342 miles, and make the angle BAC equal to $42^{\circ} 52'$, the given latitude; from B draw BC perpendicular to AB, meeting AC in C; then AC applied to the scale will measure 466½, the difference of longitude required.

By Calculation.—

L cosec lat.....	$42^{\circ} 52'$	$= 10.13493$
Log. distance.....	342	$= 2.53403$
	-10	
Log. diff. long. 466.6		$= 2.66896$
Long. Cape Finisterre.....	$9^{\circ} 17' W.$	
Diff. longitude	7 47 W.	
Longitude in.....	17 4 W.	

Ex. 5.—A ship sailed due E. 358 miles, and was found by observation to have differed her longitude $8^{\circ} 42'$; required the parallel of latitude.

By Construction.—Make the line AB (fig. 26) equal to the given distance; to which let BC be drawn perpendicular, with an extent equal to 522', the difference of longitude; describe an arc from the centre A, cutting BC in C; then the angle BAC, being measured by means of the line of chords, will be found equal to $46\frac{1}{2}^{\circ}$, the required latitude.

By Calculation.—

Log. dist.	$358+10=12.55388$
Log. diff. long. 512	$= 2.71767$
L cos lat....	$46^{\circ} 42' = 9.83621$

Ex. 6.—From two ports in Lat. $33^{\circ} 58' N.$, distance 348 miles, two ships sail directly N. till they are in Lat. $48^{\circ} 23' N.$; required their distance.

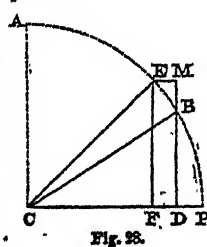

By Construction.—Draw the lines CB, CE (fig. 27), making angles with CP equal to the complements of the given latitudes, namely, $56^{\circ} 2'$ and $41^{\circ} 37'$ respectively. Make BD equal to the given distance 348 miles, and perpendicular to CP. Now from the centre C, with the radius CB, describe an arc intersecting CE in E; then EF drawn from the point E, perpendicular to CP, will represent the distance required; which being applied to the scale, will measure 278½ miles.

By Calculation, as under:—

Log. given distance	348 miles	$= 2.54158$
L cos lat. in.....	$48^{\circ} 23'$	$= 9.82226$
		12.36384
L cos lat. from	$33^{\circ} 58'$	$= 9.91874$
Log. distance required.....	278.6 miles	$= 2.44510$

Ex. 7.—Two ships, in Lat. $56^{\circ} 0' N.$, distant 180 miles, sail due S.; and having come to the same parallel, are now 232 miles distant. The latitude of that parallel is required.

By Construction.—Make DB (fig. 28) equal to the first distance 180 miles, DM equal to the second 232, and the angle DBC equal to the given latitude 56° . From the centre C, with the radius CB, describe the arc BE; and through M draw ME parallel to CD, intersecting the arc BE in E. Join EC, and draw EF perpendicular to CD; then the angle FEC will be the latitude required; which, being measured, will be found equal to $43^{\circ} 58'$.

By Calculation, as under:—

L cos lat. from.....	$56^{\circ} 0'$	$= 9.74756$
Log. distance on required parallel 232 miles		$= 2.36549$
		12.11305
Log. distance on known parallel... 180		$= 2.25527$
L cos latitude in	$43^{\circ} 53'$	$= 9.85778$

CHAP. VI.—OF MIDDLE-LATITUDE SAILING.

It has been already explained in chap. ii. that the departure is greater than the intercepted arc of the parallel of the higher latitude, and less than that of the parallel of the lower of two places between which a ship sails; but that there is an intermediate parallel, the arc of which is exactly equal to the departure. This parallel is supposed to pass through the middle point between the extreme latitudes; and hence the latitude of this point is called the middle latitude. The relations between course, distance, departure, and true difference of latitude are to be found as in chap. iii.; and the relation between the departure and difference of longitude is given by the above considerations, viz.,—

Departure = diff. long. \times cos mid. latitude.

But departure = true diff. lat. \times tan course.

Hence we get

True diff. lat. \times tan course = diff. long. \times cos mid. lat. (A.)
also departure = distance \times sin course.

Whence also

Distance \times sin course = diff. long. \times cos mid. lat. (B.)

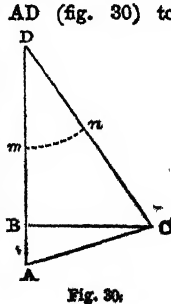

If ABC (fig. 29) be the triangle for plane sailing, where AB is the true difference of latitude, AC the distance, BAC the course, and BC the departure; at C make BCD equal to the middle latitude, and produce CD to meet AB produced in D; then CD is evidently the true difference of longitude, and all the problems may be resolved and constructed by the two triangles which have a common side, —viz., the departure BC.

Also problems in middle-latitude sailing may be solved by the traverse table; for the relations between middle latitude, difference of longitude, and departure, are the same as those between course, distance, and true difference of latitude, and may therefore be found at once by inspection from the table.

Ex. 1.—Required the compass course and distance from the Island of May, in Lat. $56^{\circ} 12' N.$ and Long. $2^{\circ} 37' W.$, to the Naze of Norway, in Lat. $57^{\circ} 50' N.$, and Long. $7^{\circ} 27' E.$; variation $2\frac{1}{4} W.$

Latitude Isle of May	$56^{\circ} 12' N.$	$56^{\circ} 12'$
Latitude Naze of Norway	$57^{\circ} 50' N.$	$57^{\circ} 50'$
Difference of latitude.....	$1\ 38=98' N.$	114 2
Middle latitude		$57^{\circ} 1$
Longitude Isle of May.....	$2^{\circ} 37' W.$	
Longitude Naze of Norway.....	$7^{\circ} 27' E.$	
Difference of longitude.....	10	$4=604' E.$

By Construction.—Draw the right line AD (fig. 30) to represent the meridian of the May; with the chord of 60° describe the arc mn , upon which lay off the chord of $32^{\circ} 59'$, the complement of the middle latitude from m to n . From D through n draw the line DC equal to $604'$, the difference of longitude; and from O draw OB perpendicular to AD; make BA, equal to $98'$, the difference of latitude, and join AO; which, applied to the scale, will measure 343 miles, the distance sought; and the angle A being measured by means of the line of chords, will be found equal to $73^{\circ} 24'$, the required course.

Ex. 4.—A ship from Lat. 26° 30' N., and Long. 45° 30' W., sailed N.E. & N. till her departure is 216 miles; required the distance run, and latitude and longitude come to. D

By Construction.—With the course and departure construct the triangle ABC (fig. 33); and the distance and difference of latitude being measured will be found equal to 340 and 263 respectively. Hence the latitude in is 30° 53', and middle latitude 28° 42'. Now make the angle BCD equal to the middle latitude, and the difference of longitude DC applied to the scale will measure 246'.

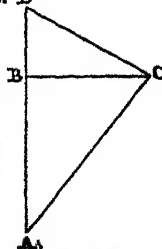

Fig. 33.

By Calculation.—To find the distance.

L cosec course	31 pts. =	10.19764
Log. departure	216 miles =	2.33445
		-10

Log. distance	340.5 =	2.53109
---------------------	---------	---------

To find the true difference of latitude.

L cot course	31 pts. =	10.08583
Log. departure	216 miles =	2.33445
		-10

CHAP. VII.—OF OBLIQUE SAILING.

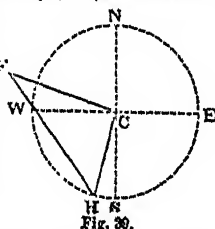

Oblique sailing is the application of oblique-angled plane triangles to the solution of problems at sea. This sailing

Oblique
Sailing.

will be found particularly useful in going along shore, and in surveying coasts and harbours.

Ex. 1.—At 11 A.M. the Girdle Ness bore W.N.W., and at 2 P.M. it bore N.W. by N.; the course during the interval S. by W. five knots an hour; required the distance of the ship from the Ness at each station.

By Construction.—Describe the circle NESW (fig. 39), and draw the diameters NS, EW at right angles to each other. From the centre C, which represents the first station, draw the W.N.W. line CF; and from the same point draw CH, S. by W., and equal to 15 miles, the distance sailed. From H draw HF in a N.W. by N. direction, and the point F will represent the Girdle Ness. Then the distances CF, HF will measure 19.1 and 26.5 miles respectively.

By Calculation.—In the triangle FCH are given the distance CH 15 miles, the angle FCH equal to 9 points, the interval between the S. by W. and W.N.W. points, and the angle CHF equal to 4 points, being the supplement of the angle contained between the S. by W. and N.W. by N. points. Hence CFH is 3 points; to find the distances CF, HF.

To find the distance CF.

Log. CH.....	15 m.	=	1.17609
L sin CHF.....	4 pts.	=	9.84948
			4.02557
L sin CFH.....	3 pts.	=	9.74474
Log. CF.....	19.07 m.	=	1.28083

To find the distance FH.

Log. CH.....	15 m.	=	1.17609
L sin FCH.....	9 pts.	=	9.99157
	= L sin 7 "		11.16766
L sin CFH.....	3 pts.	=	9.74474
Log. FH.....	26.48 m.	=	1.42292

Ex. 2.—Running up Channel E. by S. per compass at the rate of 5 knots an hour. At 11 A.M. the Eddystone Lighthouse bore N. by E. $\frac{1}{2}$ E., and the Start Point N.E. by E. $\frac{1}{2}$ E.; and at 4 P.M. the Eddystone bore N.W. by N., and the Start N. $\frac{1}{2}$ E.; required the distance and bearing of the Start from the Eddystone, the variation being $2\frac{1}{2}$ points W.

By Construction.—Let the point C (fig. 40) represent the first station, from which draw the N. by E. $\frac{1}{2}$ E. line CA, the N.E. by E. $\frac{1}{2}$ E. line CB, and the E. by S. line CD, which make equal to 25 miles, the distance run in the elapsed time. Then from D draw the N.W. by N. line DA, intersecting CA in A, which represents the Eddystone; and from the same point draw the N. $\frac{1}{2}$ E. line DB, cutting CB in B, which therefore represents the Start. Now the distance AB applied to the scale will measure 22.9, and the bearing per compass BAF will measure $73\frac{1}{2}^\circ$.

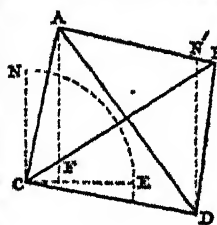

Fig. 40.

By Calculation.

The angle ACD = ACE + ECD = NCE - NCA + ECD	
	= $8 - 1\frac{1}{2} + 1$ pt. = $7\frac{1}{2}$ pts.
BCD = NCE - NCB + ECD = $8 - 5\frac{1}{2} + 1$ pt. = $3\frac{1}{2}$ pts.	
ACB = ACD - BCD.....	= 4 pts.
ADC = N'DC - N'DA.....	= 7 - 3 pts. = 4 pts.
N'DB.....	= $\frac{1}{2}$ pts.
and CDB = N'DC + N'DB.....	= $7\frac{1}{2}$ pts.
Also, CAD = 16 pts. - ACB - ADC	
	= $16 - 7\frac{1}{2} - 4$ pts. = $4\frac{1}{2}$ pts.
and CBD = 16 - BCD - CDB.....	= $16 - 3\frac{1}{2} - 7\frac{1}{2}$ = $4\frac{1}{2}$ pts.

To find AC.

Log. CD.....	25 m.	=	1.39794
L sin ADC.....	4 pts.	=	9.84948
			11.24742
L sin CAD.....	$4\frac{1}{2}$ pts.	=	9.86979
Log. AC.....	23.86 m.	=	1.37763

To find BC.

Log. CD.....	25 m.	=	1.39794
L sin BDC.....	$7\frac{1}{2}$ pts.	=	9.99948
			11.39742
L sin CBD.....	$4\frac{1}{2}$ pts.	=	9.88818
Log. BC.....	32.30 m.	=	1.50924

To find BAC.

BC - AC.....		=	8.44
BC + AC.....		=	56.16
Log. (BC - AC).....	8.44 m.	=	0.92634
L cot $\frac{1}{2}$ ACB.....	2 pts.	=	10.38278
			11.30912
Log. (BC + AC).....	56.16	=	1.74943
L tan $\frac{1}{2}$ (BAC - ABC).....	$19^\circ 56'$	=	1.55969
$\frac{1}{2}$ (BAC + ABC) =	67 30		
\therefore BAC =	87 26		
ABC =	47 34		

Hence BAF = BAC - CAF
 = $87^\circ 26' - 1\frac{1}{2}$ pts.
 = $87^\circ 26' - 14^\circ 4'$
 = $73^\circ 22' = 73\frac{1}{2}^\circ$ nearly.

To find AB, or the distance.

Log. BC.....	32.30 m.	=	1.50924
L sin ACB.....	4 pts.	=	9.84948
			11.35972
L sin CAB.....	$87^\circ 26'$	=	9.99956
Log. AB.....	22.9 m.	=	1.36016

Many other examples might be given. These and all other cases which can occur in practice are to be resolved by plane trigonometry, from calculating the triangles which the data of the given case afford.

CHAP. VIII.—OF WINDWARD SAILING.

Windward sailing is when a ship by reason of a contrary wind is obliged to sail on different tacks in order to gain her intended port; and the object of this sailing is to find the proper course and distance to be run on each tack.

Ex.—The wind at N.W., a ship bound to a port 64 miles to the windward proposes to reach it on three boards,—two on the starboard and one on the larboard tack, and each within 5 points of the wind; required the course and distance of each tack.

By Construction.—Draw the N.W. line CA (fig. 41) equal to 64 miles; from C draw CB W. by S., and from A draw AD parallel thereto and in an opposite direction. Bisect AC in E, and draw BED parallel to the N. by E. rhumb, meeting CB, AD in the points B and D. Then CB = AD applied to the scale will measure $36\frac{1}{2}$ miles, and BD = 2CB = $72\frac{1}{2}$ miles.

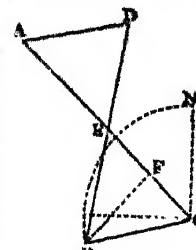

Fig. 41.

CHAP. IX.—OF CURRENT SAILING.

The computations in the preceding chapters have been performed upon the assumption that the water has no motion. This may no doubt answer tolerably well in those places where the ebbings and flowings are regular, as then the effect of the tide will be nearly counterbalanced. But in places where there is a constant current or setting of the sea towards the same point, an allowance for the change of the ship's place arising therefrom must be made. And the method of resolving these problems in which the effect of a current or heave of the sea is taken into consideration is called *current sailing*.

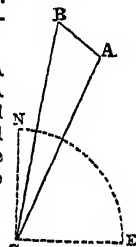

Current
Sailing.

In a calm, it is evident a ship will be carried in the direction and with the velocity of the current. Hence if a ship sails in the direction of the current, her rate will be augmented by the rate of the current; but if sailing directly against it, the distance made good will be equal to the difference between the ship's rate as given by the log and that of the current. And the absolute motion of the ship will be ahead if her rate exceeds that of the current; but if less, the ship will make sternway. If the ship's course be oblique to the current, the distance made good in a given time will be represented by the third side of a triangle, whereof the distance given by the log, and the drift of the current in the same time, are the other sides; and the true course will be the angle contained between the meridian and the line actually described by the ship.

It is evident from the above observations that we may consider the direction of the current in the light of a separate course; and by multiplying the rate of the current per hour by the number of hours it has been running, and treating this as a distance, we may estimate the ship's real place by any of the rules for compound courses.

Ex. 1.—A ship sailed N.N.E. at the rate of 8 knots an hour during 18 hours, in a current setting N.W. by W. $2\frac{1}{2}$ miles an hour; required the course and distance made good.

By Construction.—Draw the N.N.E., line CA (fig. 42) equal to $18 \times 8 = 144$ miles; and from A draw AB parallel to the N.W. by W. rhumb, and equal to $18 \times 2\frac{1}{2} = 45$ miles; now BC being joined will be the distance, and NCB the course. The first of these will measure 159 miles, and the second $6^\circ 23'$.

By Calculation.—

The angle CAB..... = 9 pts.
CA..... = 144 m.
AB..... = 45 m.
CA + AB..... = 189 m.
CA - AB..... = 99 m.
Log. (CA - AB)..... 99 m. = 1.995635
L cot $\frac{1}{2}$ CAB..... $4\frac{1}{2}$ pts. = 9.914173
11.909808
Log. CA + CB 185 m. = -2.276462
L tan $\frac{1}{2}$ (ABC - ACB) $23^\circ 15'$ = 9.633346
 $\frac{1}{2}$ (ABC + ACB) = 39 22
 \therefore ACB = $16^\circ 7'$ and ABC = 62 37
NCA = 22 30
 \therefore NCB the course..... = 6 23
Log. AB..... 45 m. = 1.653212
L sin CAB 9 pts. = 9.991574
11.644786
L sin ACB..... $16^\circ 7'$ = -9.443410
Log. BC..... 159 m. = 2.201376

Or,

For first course we have course N.N.E., or 2 points.
And distance.....144 Whence, from traverse table,
True diff. latitude.....133.0 N. Departure.....55.1 E.

For second course we have course N.W. by W., or 5 points.
And distance.....45 And from traverse table,
True diff. latitude.....25 N. Departure.....37.4 W.

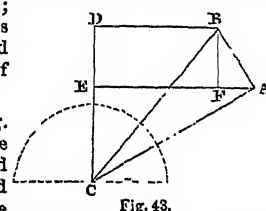

For last course—

True diff. latitude..... 158 N.
Departure..... 17.7 W.
Log. departure 17.7 + 10 = 11.24797
Log. true diff. latitude 158 = -2.19866
L tan course N. $6^\circ 23'$ E. = 9.04931
L sec course..... $6^\circ 23' - 10 =$.00271
Log true diff. latitude 158 m. = 2.19866
Log. distance 159 = 2.20137

Ex. 2.—A ship from Lat. $35^\circ 20'$ N. sailed 24 hours in a

current setting N.W. by N., and by account is in latitude $38^\circ 42'$ N., having made 44 miles of easting; but the latitude by observation is $38^\circ 58'$ N.; required the course and distance made good, and the drift of the current.

By Construction.—Make CE (fig. 43) equal to 22 miles, the difference of latitude by dead reckoning, and EA = 44 miles, the departure, and join CA; make CD = 38 miles, the difference of latitude by observation. Draw the parallel of latitude DB, and from A draw the N.W. by N. line AB, intersecting DB in B, and AB will be the drift of the current in 24 hours; CB being joined, will be the distance made good, and the angle DCB the true course. Now AB and CB applied to the scale will measure 19.2 and 50.5 respectively, and the angle DCB will be $41\frac{1}{4}^\circ$.

By Calculation.—

ABF..... = 3 pts.
BF = CD - CE..... = 16 miles.

To find AB.

Log. BF 16 m. = 1.20412
L sec ABF..... 3 pts. -10 = 0.08015
Log. AB..... 19.2 m. = 1.28427
Or drift of current..... 19.2 miles.

To find AF.

Log. BF 16 m. = 1.20412
L tan ABF..... 3 pts. -10 = 9.82489
Log. AF 10.7 m. = 1.02901
Hence BD = AE - AF = 44 - 10.7 = 33.4.

To find the course.

Log. BD 33.4 + 10 = 11.52244
Log. CD..... 38 = 1.57978
L tan course N. $41^\circ 14'$ E. = 9.94266

To find the distance.

Log. sec course..... $41^\circ 14'$ E. -10 = 0.12376
Log. CD..... 38 = 1.57978
Log. distance..... 50.5 m. = 1.70354

By Traverse Table.—Taking the current course first, true difference of latitude 16, and course N.W. by N., we find in the traverse table the corresponding distance 19.3, and departure 10.7.

Again, for second course, we have true difference of latitude 38, and departure 44 - 10.7 = 33.3 E.

Points.	Course	Distance.	Diff of Latitude.		Departure.	
			N.	S.	E.	W.
3	N.W. by N.	19.3	16	10.7
N. 41° E.	...	51	38	...	33.3	...

Whence the course and distance are found as above.

Or, from the traverse table to nearest degree and minute, we find in the columns of distance and angle, opposite to difference of latitude 38.5, and departure 35.5—distance 51, and angle 41° .

CHAP. X.—OF THE DAY'S WORK AND SHIP'S JOURNAL.

The most usual application of the principles laid down in the preceding chapters, is to ascertain from the several courses and distances run by a ship in the interval between the noons of two successive days, the ship's place at the noon of the latter day,—i.e., its latitude and longitude; its latitude and longitude being given for the noon of the preceding day. This constitutes a day's work; and the ship's place deduced therefrom is called her place by *account* or *dead reckoning*. The day aboard ship, like the astronomical day, commences at noon; and the ship's position is always calculated at every noon. In the Royal Navy, the log is hove once in every hour; but in most trading-vessels only once in every two hours. A record of the knots, and tenths of knots, run every hour or every two hours, the course, the direction of the wind, the leeway, and everything which affects the ship's place, is kept in the journal, which, for this purpose, is usually divided into six or seven columns. The first column on the left hand contains the hours

Day's
Work and
Ship's
Journal.

Ship's
Journal.

from noon to noon; the second and third, the knots and tenths of knots sailed every hour, or every two hours; the fourth contains the courses steered; the fifth, the direction of the wind; and the sixth, when there are seven columns, contains the leeway; and the last contains general remarks, including phenomena, variation, &c., &c.

The mode of forming a table showing the deviation of the compass for the several positions of the ship's head, has already been given.

The courses steered, as entered in the log-book, must be corrected for variation, deviation, and leeway. The setting and drift of current, and the heave of the sea, are to be marked down. These are to be corrected for variation only. In the day's work, it is usual to treat a current as an independent course and distance. If the ship does not sail from a place whose latitude and longitude are known (which rarely happens), the bearing of some known place is to be observed, and its distance found, which is usually done by estimation. The ship is then supposed to have taken her departure from this place, in a course exactly opposite to the observed bearing, and to have run the estimated distance on it. If there be any reason to suspect the correctness of the estimated distance, it will be easy to obtain the true distance as follows:—Let the bearing be observed of the place from which the departure is to be taken; and the ship having run a certain distance on a direct course, the bearing of the same place is again to be observed. We shall then have a triangle, all of whose angles are known from the observed bearings, and one of its sides, viz., the distance the ship has sailed. The other two sides, viz., the distance of the ship from the place of departure at each of the observations, can be immediately found, as in problem 1 on "Oblique Sailing." The distances for each course may be obtained by adding together the hourly distances. The courses being thus corrected, and the distances found, the latitude and longitude may be found by any of the methods explained in chap. iv. As the differences of latitude are not usually great, the traverse table may generally be made use of for finding the latitude in; and having found the middle latitude, the longitude may be obtained by the middle latitude method.

The following example will enable the reader to apply the directions we have just given:—

Ex.—September 12, 1857, at noon, a point of land in Lat. $64^{\circ} 20'$ S., and Long. $69^{\circ} 40'$ E., bore by compass S.E., distant 15 miles (ship's head being E.), afterwards sailed as by the following log-account; and the latitude and longitude in, on September 13, at noon.

In this example the true differences of latitude and departures are taken by inspection from the traverse table.

When a ship is bound for a distant port, the bearing and distance of the port must be found. This may be done by calculation or by a chart. If islands, capes, or headlands intervene, it will be necessary to find the several courses and distances between each successively. The true course between the places must be reduced to the compass course

Day's
Work and
Ship's
Journal.

Sea Charts. by making the requisite allowances for variation and deviation, as already explained.

In hard blowing weather, with a contrary wind and a high sea, it is impossible to gain any advantage by sailing. In such cases, therefore, the object is to avoid as much as possible being driven back. With this intention it is usual to lie to under no more sail than is sufficient to prevent the violent rolling to which the vessel would be otherwise subjected, to the endangering of her masts and straining her timbers, &c. When a ship is brought to, the tiller or wheel is put down over to the leeward, which brings her head round to the wind. The wind having then little power over the sails, the ship loses her way through the water; and the action of the water on the rudder ceasing, her head falls off from the wind, the sail which she has set fills, and gives her fresh way through the water, which, acting on the rudder, brings her head again to the wind. Thus the ship has a kind of oscillating motion, coming up to the wind and falling off from it again alternately. The middle point between those upon which she comes up and falls off is taken for her apparent course; and the leeway, variation, and deviation are to be allowed from this to find the true course.

It is generally found that the latitude by account does not agree with that by observation. On considering the imperfections of the common log-line, and the uncertainty with regard to variation, an exact agreement of latitudes cannot be expected. When the difference of longitude is to be found by dead reckoning, and the latitudes by account and observation disagree, several writers on navigation have proposed to apply a conjectural correction to the departure or difference of longitude. Thus, if the course is near the meridian, the error is wholly attributed to the distance, and the departure is to be increased or diminished accordingly; if near the parallel, the course only is supposed to be erroneous; and if the course is towards the middle of the quadrant, the course and distance are both assumed to be in error. This last correction will, according to different authors, place the ship upon opposite sides of her meridian by account. As these corrections, therefore, are no better than guessing, they should be absolutely rejected.

If the latitudes do not agree, the navigator should examine his log-line and half-minute glass, and correct the distance accordingly. He is then to consider if the variation and leeway have been properly ascertained; if not, the courses are to be again corrected, and no other alteration whatever is to be made in them. He is next to observe if the ship's place has been affected by a current or heave of the sea, and to allow for them according to the best of his judgment. By applying these corrections, the latitudes will generally be found to agree tolerably well; and the longitude may be corrected in the same way.

It will be proper for the navigator to determine the longitude of the ship by observation as often as possible, and the reckoning is to be carried forward in the usual manner from the last good observation; yet it will perhaps be very satisfactory to keep a separate account of the longitude by dead reckoning. The modes of finding the latitude and longitude of a ship by observation, and the variation of the compass, will be given in the next book.

CHAP. XI.—OF SEA CHARTS.

The charts usually employed in the practice of navigation are the *Plane* and *Mercator's charts*. The former of these is adapted to represent a portion of the earth's surface near the equator, where the change in the lengths of corresponding arcs of the parallel is very small; and the other for all portions of the earth's surface. (For a particular description of these, see the articles *CHART* and *GEOGRAPHY*.) We shall here only describe their use.

Use of the Plane Chart.

Sea Charts.

PROB. I.—To find the latitude and longitude of a place on the chart.

Rule.—Take the least distance of the given place from the nearest parallel of latitude; this distance applied to the graduated meridian from the extremity of the parallel will give the latitude of the place. In the same way the longitude is found by taking the least distance from the nearest meridian, and applying it to the graduated parallel.

Thus the distance between Bonavista and the parallel of 15° being laid from that parallel on the graduated meridian, will reach to $16^{\circ} 5'$, the latitude required.

PROB. II.—To find the course and distance between two given places on the chart.

Rule.—Lay a ruler over the given places; if a parallel ruler be used, keeping the edge of one ruler passing through the places fixed, move the other until it passes through the centre of one of the compasses on the chart; the point of the compass through which this edge passes will show the course.

Or, generally, let a line on the edge of another ruler be placed so as to be parallel to the first ruler, and to pass through the centre of a compass; it will cut the circumference in a point which will determine the course.

The interval between the places being applied to the scale will give the distance.

Thus the course from Palmas to St Vincent will be found to be about S.S.W. $\frac{1}{4}$ W., and the distance $13\frac{1}{2}^{\circ}$ or 795 miles.

PROB. III.—The course and distance sailed from a known place being given, to find the ship's place on the chart.

Rule.—Lay a ruler over the given place parallel to another ruler laid over one of the compasses, with one edge passing through the centre, and the other the point on the circumference which shows the course, and lay off on it the distance taken from the scale; it will give the point representing the ship's present place.

Thus, supposing a ship has sailed S.W. by W. 160 miles from Cape Palmas; then by proceeding as above, it will be found that she is in Lat. $2^{\circ} 57' N$.

The reader will have no difficulty in solving various other problems by means of this chart, being, in fact, only the construction of the various problems in plane sailing on this chart.

Use of Mercator's Chart.

The method of finding the latitude and longitude of a place, and the course or bearing between two given places, is the same as in the plane chart, which see.

PROB. I.—To find the distance between two given places on the chart.

CASE 1.—When the given places are under the same meridian.

Rule.—The difference or sum of their latitudes, according as they are on the same or on opposite sides of the equator, will be the distance required.

CASE 2.—When the given places are under the same parallel.

Rule.—If that parallel be the equator, the difference or sum of their longitudes, according as they are on the same or on opposite sides of the first meridian, is the distance; otherwise take the distance between the places, lay it off upwards and downwards from the given parallel, and the intercepted degrees will be the distance between the places.

Or take an equal extent of a few degrees on the meridian on each side of the parallel; and the number of extents and parts of an extent contained between the places, multiplied by the length of an extent, will give the required distance.

Observation Instruments.

CASE 3.—When the given places differ both in latitude and longitude.

Rule.—Find the difference of latitude between the given places, and take it from the equator or graduated parallel; then lay a ruler over the places, and move one point of the compass opened to the difference of latitude just found along the edge of the ruler till the other just touches a parallel; then the distance from the point of the compass on the ruler to the point of intersection of the ruler and the parallel, applied to the equator, will give the distance between the places in degrees and parts of a degree, which, multiplied by 60, will give it in miles.

PROB. II.—Given the latitude and longitude in; to find the ship's place by the chart.

Rule.—Lay a ruler over the given latitude, and lay off the given longitude from the first meridian by the edge of the ruler, and the ship's present place will be obtained.

PROB. III.—Given the course sailed from the given place, and the latitude in; to find the ship's present place on the chart.

Rule.—Lay a ruler over the place sailed from, in the direction of the given course; its intersection with the parallel of latitude in, will give the ship's present place.

PROB. IV.—Given the latitude and longitude of the place left, and the course and distance sailed; to find the ship's present place on the chart.

Rule.—Lay a ruler over the given place, in the direction of the given course, take the distance sailed from the equator, and put one point of the compass opened to this distance at the intersection of the ruler with any parallel, and the other point will reach to a certain place by the edge of the ruler. This point being kept fixed, draw in the other point of the compass until it just touch the above parallel when swept round; apply this extent to the equator, and it will give the difference of latitude. Hence the latitude in is known; and the intersection of the edge of the ruler with the parallel of this latitude will give the ship's present place.

The above problems sufficiently illustrate the use of Mercator's Chart. The reader will have no difficulty in solving other problems by means of it.

BOOK II.

CONTAINING THE METHODS OF FINDING THE LATITUDE AND LONGITUDE OF THE SHIP AT SEA, THE VARIATION OF THE COMPASS, AND TIME OF HIGH WATER.

CHAP. I.—DESCRIPTION AND USE OF INSTRUMENTS USED IN OBSERVATIONS.

SECT. I.—OF HADLEY'S SEXTANT AND QUADRANT.

The principal difference between these instruments is in the extent of the angle which can be observed by them; and in the more elaborate and careful workmanship of the latter of the two. Indeed the quadrant is only available for taking observations which determine the latitude. The distances of the moon from the sun or other heavenly body, which are frequently used for the determination of the longitude, can only be observed by the help of the sextant.

Allowing for these differences, the principle on which the quadrant and sextant are constructed is the same. In the Royal Navy sextants are almost exclusively in use, although quadrants are still employed for the observation of altitudes in many trading vessels. The sextant, therefore, will first be described, and afterwards those points in which the quadrant differs from the sextant will be explained.

The reader is supposed to be aware of the ordinary laws with regard to the propagation and reflection of light, viz.,—

that in the same medium, light is propagated in straight lines, the smallest conceivable quantity of which that can be stopped or propagated alone is called a ray; and that when a ray of light is incident on a plane reflecting surface, it is bent or reflected after incidence in such manner, that the incident and reflected rays and the straight line perpendicular to the mirror at the point of incidence (called the normal to the surface) lie all in one plane; and that the incident and reflected rays make equal angles with the normal or the surface.

Observation Instruments.

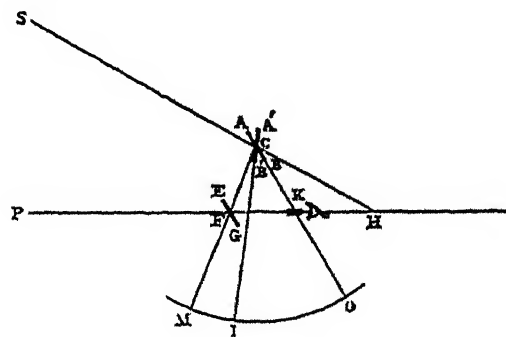

Fig. 44.

Let MO (fig. 44) be an arc of a circle, CO and CM two radii, and CI be a moveable radius carrying a plane mirror, silvered through its whole extent, firmly fixed to it; EFG another mirror, the lower part of which FG only is silvered, while the upper part EF is unsilvered, so that a ray reflected from the lower portion FG in direction FH , and a direct ray PFH through the unsilvered part EF , may be seen together by an eye at K . This mirror is fixed to the radius CM in such a manner that when the moveable radius occupies the position ACO , the two mirrors ACB and EFG are both perpendicular to the plane of the instrument, and parallel to one another.

Let now S and P be two distant objects whose angular distance is required to be found. Let the instrument be placed so that its plane passes through S and P , and that a ray from P , passing through the unsilvered glass EF , may be seen directly by an eye at K ; and while in this position let the bar be moved round C , CI carrying the mirror with it until a ray from S , falling on ACB , is reflected in the direction CF , and again reflected by FG in the direction FH ; so that to the eye at K the images of the two objects S and P are seen together, or coincide.

Produce SA to meet PFH in H ; then SHP is the angle through which the ray SA has been deflected, and is also the angular distance between S and P . Let $A'B'$ be the new position of the mirror AB ; then ACA' is the angle through which the mirror has turned, and consequently also the angle through which CI has moved.

Now angle of deflection

$$\begin{aligned} SHP &= SCF - CFH \\ &= 180^\circ - 2 FCB' - (180^\circ - 2 EFC) \end{aligned}$$

because by law of reflection,

$$SCA' = FCB'; \text{ and therefore}$$

$$SCF = 180^\circ - SCA' - FCB' = 180^\circ - 2 FCB',$$

and $EFC = GFH$; and therefore

$$\begin{aligned} CFH &= 180^\circ - EFC - GFH \\ &= 180^\circ - 2 EFC; \end{aligned}$$

$$\therefore SHP = 2 EFC - 2 FCB'.$$

But $EFC = FCB$, because EFG is parallel to ACB ;

$$\text{or } SHP = 2 FCB - 2 FCB' = 2 ACA'$$

= twice the angle through which CI has moved.

Hence if the arc OM be divided into degrees, and each degree marked as two degrees, the reading off of the arc OI will be the angle between the distant objects S and P .

Observation Instruments. An instrument constructed on this principle, whose circular arc or limb is a sixth part of a circle, and therefore capable of measuring angles up to 120° , is called a sextant; if the limb contain only an eighth part of a circle, it is a quadrant, and can only measure angles up to 90° .

The Sextant.

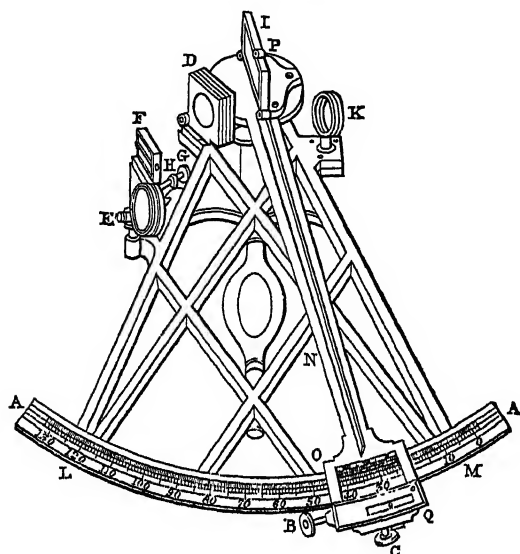

Fig. 45.

- (1.) PLM (fig. 45) is the frame of the sextant.
- (2.) AA the graduated arc or limb.
- (3.) N the index, carrying the vernier OQ.
- (4.) I the index-glass.
- (5.) F the horizon-glass.
- (6.) D the coloured or dark glasses between the index-glass and horizon-glass.
- (7.) E the coloured glasses behind the horizon-glass.
- (8.) K the tube or collar in which the telescope is inserted.

The frame of the sextant. The frame of the sextant consists of an arc AA, firmly attached to the two radii LP, MP, which are bound together by braces, as shown in the figure, to prevent warping and liability to bend.

The index. The index N is a flat bar of brass, and turns on the centre of the sextant; at the lower end of the index there is an oblong opening; to one side of this opening the vernier scale is attached to subdivide the divisions of the arc; at the end of the index there is a piece of brass which bends under the arc, carrying a spring to make the vernier scale lie close to the divisions. It is furnished with a finger-screw C, by which the index is fixed in any position to the limb of the instrument. There is also an adjusting-screw B attached to the index, capable of moving it with greater accuracy than the hand; this screw does not act until the index is fixed by the finger-screw C. Care must be taken not to force the adjusting-screw when it arrives at either extremity of its adjustment. When any considerable movement is required to be given to the index, the screw C at the back of the sextant must be set free; but where the index is brought nearly to the divisions required, this back screw should be tightened, and then the index gradually moved by the adjusting-screw.

The index-glass. Upon the index, and near its axis of motion, is fixed a plane speculum or mirror of glass I, quicksilvered. It is set in a brass frame, which is firmly fixed by a strong cock to the centre plate of the index, with its face perpendicular to the plane of the instrument. This mirror being fixed to the index, moves along with it, and has its direction changed by the motion thereof. As has already been observed, this glass

is to receive the rays from the sun or other object, and reflect them upon the horizon-glass. It is furnished with screws at its back, the object of which is to replace it in a perpendicular position, if by any accident it has been deranged.

To the radius PL is attached a small speculum F, whose surface is parallel to the index-glass when zero on the horizon-glass index coincides with zero on the limb. The under part only of this speculum is silvered, the upper half being left transparent, and the back part of the frame cut away, that nothing may impede the sight through the unsilvered part of the glass. The edge of the foil of this glass is nearly parallel to the plane of the instrument, and ought to be very sharp, and without a flaw. It is set in a brass frame, which turns on axes and pivots which move in an exterior frame; the holes in which the pivots move may be tightened by four screws in the exterior frame. G is a screw by which the horizon-glass may be set perpendicular to the plane of the instrument. Should this screw become loose, or move too easy, it may be easily tightened by turning the capstan-headed screw H which is on one side of the socket through which the stem of the finger-screw passes; this screw G is in some instruments under the glass, in others behind it, and in others at the side.

There are four coloured glasses at D, tinged red and green, each of which is set on a separate frame that turns on a centre. They are used to defend the eye from the brightness of the solar image and the glare of the moon, and may be used separately or together as occasion may require. There are three more such glasses placed behind the horizon-glass at E, to weaken the rays of the sun or moon when viewed directly through the horizon-glass. The paler glass is sometimes used in observing altitudes at sea to take off the strong glare of the horizon.

The sextant is furnished with a plane tube K; and in order to render objects distinct, it has two telescopes—one Galileo's telescope, representing the objects erect in their natural position; the longer one, an astronomical telescope, shews them inverted. It has a large field of view; and has parallel wires placed in the principal focus, where a true image of the object viewed by it is seen; thus rendering the position of the image more exact and more easy to be read off, and is that which should be used in taking observations at sea when great accuracy is required. A little use will soon accustom the observer to the inverted position, and to manage the instrument with ease. By a telescope the contact of the images is more perfectly distinguished; and by the place of the images in the field of view, it is easy to perceive whether the sextant is held in the proper position for observation. By sliding the tube that contains the eye-glasses in the inside of the other tube, the object is suited to different eyes, and made to appear perfectly distinct and well-defined.

The telescopes are to be screwed into a circular ring at K; this ring rests on two points against an exterior ring, and is held to it by two screws; by turning one of these screws, and tightening the other, the axis of the telescope may be set parallel to the plane of the sextant. The exterior ring is fixed on a triangular brass stem which slides in a socket, and, by means of a screw at the back of the sextant, may be raised or lowered so as to move the centre of the telescope to that part of the horizon-glass which shall be deemed most fit for observation. Tinged glasses are provided to screw on the eye-end of either of the telescopes or the plane tube.

The limb of the sextant is divided from right to left into 120 primary divisions, which are to be considered as degrees; the degree is subdivided in some cases into two equal parts, each of which is $30'$; in others into three equal parts, each of which is $20'$; and in others again into six equal parts, each of which is $10'$. If the zero of the index stand exactly at one of the divisions of the limb, the

Observation Instruments. reading off in that case is immediately known. If, however, the zero of the index do not stand exactly at one of the divisions, but distant from it by a small space, the value of this space is known by means of the divisions of the vernier-plate to the left of 0.

Reading off divisions on the limb, and the vernier. The vernier contains a space equal to nineteen divisions of the limb, and is divided into twenty equal parts; hence the difference between a division on the vernier and a division on the limb is one-twentieth of a division of the limb, or $1'$, if the interval between divisions on the limb is equal to $20'$. Or supposing the limb divided into intervals of $10'$, and that fifty-nine divisions of the limb correspond to sixty divisions of the vernier; it is then evident that the difference between a division of the instrument and of the vernier is $\frac{1}{60}$ th part of $10'$, i.e., $10''$. This is the most usual kind of division.

To find the actual reading off in any particular case, we must observe which division of the vernier coincides with a division of the limb; the number denoting this, multiplied by the value of the difference between a division of the limb and of the vernier, will give the additional reading. Suppose, for instance, the nearest division of the limb to the zero of the vernier to be $25^\circ 30'$, and the eighth division of the vernier to be coincident with a division of the limb, the additional angle will be $80''$ or $1' 20''$, and the reading off will be $25^\circ 31' 20''$.

Adjustments of the sextant. The adjustments of the sextant are to set the mirrors perpendicular to the plane of the instrument, and parallel to one another when the index is at zero; and to set the axis of the telescope parallel to the plane of the instrument.

Adjustment 1.—To set the index-glass perpendicular to the plane of the sextant.

Set the index towards the middle of the limb, and hold the sextant so that its plane is nearly parallel to the horizon; then look into the index-glass, and if the portion of the limb seen by reflection appears in the same plane with the limb seen directly, the speculum is perpendicular to the plane of the instrument. If they do not appear in the same plane, i.e., if the image be seen above or below the arc itself, its position must be gradually and carefully changed by means of the screws at its back until the error is rectified.

Adjustment 2.—To set the horizon-glass perpendicular to the plane of the instrument.

Place the instrument horizontal, and direct the sight to a distant well-defined object, as the sun, so as to view it directly; then move the index until the image of the object seen by reflection is on the field of view, and move the index backwards and forwards so as to make the image pass over the object. If it pass exactly over the object, the fixed mirror is perpendicular to the plane of the instrument; if not, move the screw G until their exact coincidence takes place.

Adjustment 3.—To set the horizon-glass parallel to the index-glass when the zero of the index or vernier-plate coincides with the zero of the graduations of the limb.

Set 0 on the index exactly to 0 on the limb, and fix it in that position by the screw on the under side of it; hold the sextant with its plane vertical, and direct the sight to a well-defined part of the horizon; then if the horizon seen on the silvered part coincides with that seen through the transparent part, the horizon-glass is adjusted; but if the horizons do not coincide, the position of the glass must be altered by moving a screw placed near the fixed reflector, which gives it a motion about an axis perpendicular to the plane of the instrument.

This adjustment is seldom made, as turning the adjusting-screw too often renders this part of the instrument very apt to get out of order. It is usual, therefore, to determine the error in the reading called the *Index Error*.

To do this, direct the sight to the horizon, and move the index until the reflected horizon coincides with that seen

by direct vision; then the difference between 0 on the limb and 0 on the vernier-plate will be the *index error*, which is to be added when 0 of the vernier is to the right of 0 on the limb; otherwise subtracted.

Observation Instruments.

A more accurate method than the above is to measure the sun's apparent diameter twice with the index placed alternately on the right and on the left of the zero point of the graduated limb. Half the difference of these two measures will be the index error, which must be added to, or subtracted from, all observations, according as the diameter measured with the index to the left of 0 is less or greater than the diameter measured with the index to the right of the beginning of the divisions. Care must be taken to measure the sun's horizontal diameter, as the vertical diameter is often affected with refraction. This must be done by keeping the plane of the instrument at right-angles to the vertical diameter of the sun.

For example, on January 2, 1857, the sun's diameter, measured with the index first to the right and secondly to the left of the zero point of division, was $33'$ and $32' 20''$ respectively, and the index error obtained by taking the semidifference is $-20''$.

Adjustment 4.—To set the axis of the telescope parallel to the plane of the instrument.

Turn the eye-end of the telescope until the two wires are parallel to the plane of the instrument; and let two distant objects, or two stars of the first magnitude, be selected, whose distance is not less than 90° or 100° ; make the contact of these as perfect as possible at the wire nearest the plane of the instrument; fix the index in this position; move the sextant until the objects are seen at the other wire, and if the same points are in contact, the axis of the telescope is parallel to the plane of the sextant. If, however, the objects are apparently separated, or overlap one another, correct half the error by the screws in the circular part of the supporter, one of which is above, and the other between the telescope and sextant; turn the adjusting-screw at the end of the index till the limbs are in contact; then bring the objects to the wire next the instrument, and if the limbs are in contact, the axis of the telescope is adjusted; if not, proceed as at the other wire, and continue till no error remains. In practice, this adjustment is usually made by means of the sun and moon. The mode of bringing the limbs of the sun and moon into contact will be explained when the use of the sextant is treated of. It is sometimes necessary to know the angular distance between the wires of the telescope; to find which, place the wires perpendicular to the plane of the sextant, hold the instrument vertical, direct the sight to the horizon, and move the sextant in its own plane till the horizon and upper wire coincide; keep the sextant in this position, and move the index till the reflected horizon is covered by the lower wire, and the difference of readings off in these two positions will be the angular distance between the wires. Other and better methods will readily occur to the observer on land.

The Quadrant.

It has been already observed, that this instrument differs from a sextant in the extent of the divided limb and in its rougher manufacture. It is only calculated for observing altitudes. Fig. 46 represents a quadrant of the common construction.

The frame, index, index-glass, and F the fore horizon-glass, are much the same as in the sextant. There is, besides, another horizon-glass G, called the *back* horizon-glass attached to the same radius as F. Instead of a tube or telescope, the quadrant is furnished with vanes or sights H and I. There are but three coloured glasses, two of which are red and the other green. They are fixed at K, as shown in the figure, when the fore horizon-glass is used.

Observation Instruments. If the back horizon-glass be used, they are transferred to N. The back horizon-glass is silvered at both ends, but has a

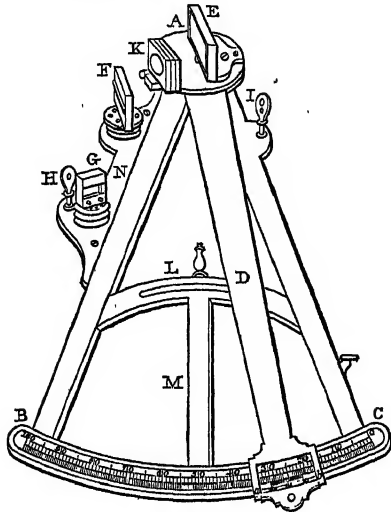

Fig. 46.

transparent slit in the middle through which the horizon may be seen. Each of the horizon-glasses is set in a brass frame, to which there is an axis passing through the wood-work, and is fitted to a lever on the under side of the quadrant, by which the glass may be turned a few degrees on its axis, in order to set it parallel or perpendicular, according as it is the fore or back horizon-glass, to the index-glass. The lever has a contrivance to turn it slowly, and a button to fix it. To set the glasses perpendicular to the plane of the instrument, there are two sunk screws, one before and the other behind each glass; these screws pass through the plate on which the frame is fixed into another plate; so that by loosening one and tightening the other of these screws, the direction of the frame, with its mirror, may be altered, and set perpendicular to the plane of the instrument.

The sight-vanes H and I are perforated pieces of brass, designed to direct the sight parallel to the plane of the quadrant. The vane I has two holes, one exactly at the height of the silvered part of the horizon-glass, the other a little higher, to direct the sight to the middle of the transparent part of the mirror.

The limb is divided into ninety primary divisions, which are considered as degrees, and each degree subdivided into three equal parts, which are therefore of 20' each. The vernier-plate is generally so divided as to enable the observer to read off accurately to minutes.

These consist in setting the mirrors perpendicular to the plane of the instrument, and the fore horizon-glass parallel, and the back horizon-glass perpendicular to the index-glass, when the zero of the index or vernier-plate coincides with zero of the graduations on the limb.

The adjustments for the index-glass and fore horizon-glass are performed nearly in the same way as for the sextant. The index error, however, must be ascertained by bringing the horizon by reflection into the same line with the horizon seen directly. The method by taking the distance of two stars of the first magnitude, or the sun and moon, is inapplicable here.

The back horizon-glass is so seldom used, that for its adjustments and the mode of taking observations with it, the reader is referred to Norie's *Navigation*, and other works in which this subject is treated.

The altitude of an object may be determined by either instrument, and is the reading off on the limb, with the proper index error applied, when by reflection that object appears to be in contact with the horizon. The distance between the sun and moon, or other heavenly bodies, may

be observed by the sextant when the limbs of the bodies whose distance is required appear to be in contact. If the quadrant be used for taking the altitude of the sun, when it is so bright that its image may be seen in the transparent part of the fore horizon-glass, the eye is to be applied to the upper hole in the sight-vane, otherwise to the lower hole; and in this case the quadrant is to be held so that the sun be bisected by the line of separation of the silvered and transparent parts of the glass. The moon is to be kept as nearly as possible in the same position, and the image of the star is to be observed on the silvered part of the glass adjacent to the line of separation of the two parts.

With the quadrant two different methods of taking observations may be employed. In the first, the observer faces the sun, and looks to that part of the horizon which is immediately under the sun, and the observation is therefore called the *fore observation*. In the other method, the observer's back is towards the sun, and he looks to the part of the horizon opposite to that which is under the sun; and this is consequently called the *back observation*. It is not to be employed except when the horizon under the sun is obscured, or rendered indistinct by fog or other impediment.

In all cases of taking altitudes, it must be considered that it is necessary to be quite sure that the distance of the sun or other body from the horizon is the least possible, otherwise it would not be the altitude that is observed. Consequently, after the instrument has been placed as nearly as possible in a vertical position, and a contact made, a motion about the line of sight of the sun must be communicated to the instrument, so as to keep the image always in the same part of the silvered mirror, the plane of the instrument being inclined. In this way we keep the angular distance of the sun from the line through the eye by which it is viewed the same, and the sun's image describes a small circle, whose angular radius is this distance. The horizon being fixed and viewed directly, will always occupy the same position. If, then, on giving this vibratory motion to the instrument, the arc described by the sun touches the horizon, the angular distance observed is the altitude. If it should cut the horizon, so that a portion of the sun's image goes below it, the index must be moved back until this arc simply touches the horizon. In the back observation with the quadrant, and in observing with the sextant furnished with the inverting telescope, the images are inverted, and the arc described by the sun's image lies below the horizon, to which line it is convex.

The motion must be given round the axis passing through the observer's eye and the sun. To do this, a motion about the axis of vision must be given to the instrument, and at the same time the observer must turn himself about upon his heel; for the motion about the line of sight of the sun may be resolved into these two motions; and the observer has no means of giving the requisite motion directly by one movement. When the sun is near the horizon, the line from the eye to the sun will not be far removed from the axis of vision, and the principal motion of the instrument will be performed on this axis; while that part of the motion made about the vertical axis will be small. On the contrary, if the sun be near the zenith, the line from the eye to the sun is nearly vertical and perpendicular to the axis of vision; hence the motion about the vertical axis is the greatest, and that about the axis of vision very trifling. In intermediate positions of the sun the motions of the instrument about these two axes will be more equally divided. When the distance between the moon and sun, a planet or a star, is to be observed, the sextant must be so held that its plane may pass through the eye of the observer and both objects; and the reflected image of the brighter of the two is to be brought into contact with the other seen directly. To effect this, therefore, it is evident that when the brighter object is to the right of the other, the face of the sextant

Observation Instruments.

Adjustments of Hadley's sextant.

Use of Hadley's sextant and quadrant.

Observation Instruments. must be held upwards, and if to the left, downwards. When the face of the sextant is held upwards, the instrument should be supported with the right hand, and the index moved with the left hand. But when the face of the sextant is from the observer, it should be held with the left hand, and the motion of the index regulated with the right hand. Sometimes a sitting posture will be found convenient for the observer, particularly when the reflected object is to the right of the direct one. In this case the instrument is supported by the right hand; the elbow may rest on the right knee; the right leg at the same time resting on the left knee. If the sextant be provided with a ball and socket, and a staff, one of whose ends is attached thereto, and the other rests in a belt fastened round the observer's body, the greater part of the weight of the instrument will be supported by his body. In all cases where the sextant is used, when the contact is nearly made, the index should be fixed by the under screw, and the remaining small motion given by the adjusting screw.

Causes of error in the use of sextant or quadrant. Error may arise from two kinds of causes: one inherent in the construction of the instrument—as defect of parallelism or perfect planeness in the fore and back surfaces of the mirrors, as also of the coloured glasses, and of the true circular form of the arc, and true centring, for which no remedy can be provided; and the other arising from the bending and elasticity of the index or moveable radius.

The parallelism of the two surfaces of the mirrors may be tested by viewing through them obliquely a distant distinct object. If the image is perfect and well defined, the surfaces are parallel; otherwise not.

To ascertain whether the surfaces of the mirrors are plane, observe the angle between two distant objects which are nearly of the same altitude, the image of the left-hand object being brought into contact with the right-hand object viewed directly; then move the instrument in its own plane so as to bring the image of the right-hand object into contact with the left-hand object viewed directly. If they continue in contact, the surfaces are plane; otherwise not.

To test the form of the dark glasses, measure the sun's diameter to the right and to the left of the zero point with different combinations of the glasses. If the sum of the diameters so measured be nearly equal to four times the semidiameter given in the *Nautical Almanac*, the form of the glasses is satisfactory. For the true centering of the arc, and its truly circular form and correct graduation, the navigator must trust entirely to the skill of the maker.

By reason of the bending and elasticity of the index, and the resistance it meets with in turning round the centre, its extremity, on being pushed round the arc, will sensibly advance before the index-glass begins to move, and may be seen to recoil when the force acting on it is removed. Mr Hadley, in order to remedy this defect, which he seems to have apprehended, gave special directions that the index be made broad at the end next the centre, and the centre or axis itself have as easy a motion as is consistent with steadiness; that is, an entire freedom from looseness or *shake*, as the workmen term it. By strictly complying with these directions, the error in question may indeed be greatly diminished, so as to be nearly insensible, when the index is made strong, and the proper medium between the two extremes of a shake at the centre on the one hand, and too much stiffness there on the other, is nicely hit; but it cannot be entirely corrected, for to more or less of bending the index will always be subject, and some degree of resistance will remain at the centre, unless the friction there could be totally removed, which is impossible.

Of the reality of the error to which he is liable from this cause, the observer, if he is provided with an instrument furnished with an adjusting screw for the index, may thus satisfy himself:—After finishing the observation, lay the instrument on a table, and note the angle; then cautiously

loosen the screw which fastens the index, and it will immediately, if the instrument is not remarkably well constructed, be seen to start from its former situation, more or less according to the perfection of the joint and strength of the index. This starting, which is due to the index recoiling after being released from the confined state it was in during the observation, will sometimes amount to several minutes; and its direction will be opposite to that in which the index was moved by the screw at the time of finishing the observation. But how far it affects the truth of the observation depends on the manner in which the index was moved in setting it to 0, for adjusting the instrument, or in finishing the observations necessary for finding the index error.

The easiest and best rule to avoid these errors seems to be this:—In all observations made by Hadley's quadrant or sextant, let the observer take notice constantly to finish his observations by moving the index in the same direction which was used in setting it to 0 for adjusting, or in the observations necessary for finding the index error. If this rule is observed, the error arising from the spring of the index will be obviated. For as the index was bent the same way, and in the same degree, in adjusting as in observing, the truth of the observations will not be affected by this bending.

Observation Instruments.

To Observe the Sun's Altitude at Sea.

Turn down one of the dark glasses before the horizon-glass (if the instrument be the quadrant, the fore horizon-glass is to be used) according to the sun's brightness; direct the sight to that part of the horizon which is under the sun, and move the index until the coloured image of the sun appears in the horizon-glass. Then give the instrument a slow vibratory motion about the axis of vision, as already described; move the index until the upper or lower limb of the sun is nearly in contact with the horizon at the lowest or highest part of the arc (according as the image is seen erect or inverted) described by this motion; and complete the contact by the tangent-screw, if the sextant be used—if not, by moving the index. The reading off of the limb will be the altitude of the sun.

To Observe the Moon's Altitude at Sea.

Turn down the green glass, and observe the moon in the silvered part of the horizon-glass, the eye being directed towards the horizon; move the index gradually, and proceed as already described in the case of the sun, until the enlightened limb is in contact with the horizon at the lowest or highest point of the arc described by the vibratory motion. The reading off will be the altitude of the moon's observed limb. If the lower limb be observed, the moon's semidiameter must be added; and if the upper limb be observed, it must be subtracted from the observed altitude, in order to obtain the altitude of the moon's centre. If the observation is made in the day-time, the coloured glass is not to be used.

To Observe the Altitude of a Star or Planet.

Put the index to zero; then direct the sight to the star so as to see it through the unsilvered part of the horizon-glass; turn the instrument a little to the left, and the image of the star will be seen in the silvered part of the glass. Now move the index, and the image will be seen to descend; continue to move the index gradually, until the star is in contact with the horizon at the lowest point of the arc described by the vibratory motion; in the case of the sextant, clamping the index when the contact is nearly made, and completing it with the adjusting or tangent screw.

Observation Instruments.

To find the Altitude of the Sun on Shore with an Artificial Horizon.

A flat dish, containing a small quantity of mercury, is generally used for this purpose. The surface of the mercury is horizontal, and is a good reflector of the sun's rays. Let the observer so stand that he may receive on his eye rays from the sun which have been reflected from the surface of the mercury. He will then, according to the principles of optics, see the reflected image of the sun as much below the surface of the mercury as the sun is above it. If, then, he looks at the image through the unsilvered part of the horizon-glass, instead of at the horizon, and brings the image of the sun reflected at the index-glass and horizon-glass into contact with this, it is evident that the angle observed will be double of the sun's altitude. The details of this process are the same as have been already explained. Having read off the angle when the contact has been made, it must be corrected for the index error; and the result, divided by 2, will be the apparent altitude of that limb of the sun which has been observed.

To Observe the Distance between the Moon and any Celestial Object with the Sextant.

1. *Between the Sun and Moon.*—Put the telescope in its place, and the wires parallel to the plane of the instrument; and if the sun is very bright, raise the plate before the silvered part of the speculum; direct the telescope to the transparent part of the horizon-glass, or to the line of separation of the silvered and transparent parts, according to the brightness of the sun; and turn down one of the coloured glasses. Then hold the sextant so that its plane produced may pass through the sun and moon, having its face upwards or downwards, according as the sun is to the right or left of the moon; direct the sight through the telescope to the moon, and move the index till the limb of the sun is nearly in contact with the illuminated limb of the moon; now clamp the index, and, by a gentle motion of the instrument, make the image of the sun move alternately to one side and the other of the moon; and when in that position, where the limbs are nearest each other, make the contact of the limbs perfect by the tangent-screw; this being effected, read off the degrees and parts of a degree shown by the index on the limb, using the magnifying-glass; and thus the angular distance between the nearest limbs of the sun and moon is obtained.

2. *Distance between the Moon and a Planet or Star.*—Direct the middle of the field of the telescope to the line of separation of the silvered and transparent parts of the horizon-glass; if the moon is very bright, turn down the lightest-coloured glass, and hold the sextant so that its plane may be parallel to that passing through the eye of the observer and both objects; its face being upwards if the moon is to the right of the star, but downwards if it be to the left. Now direct the sight through the telescope to the star, and move the index till the moon appears by the reflection to be nearly in contact with the star; clamp the index, and turn the adjusting or tangent screw till the coincidence of the star and the enlightened limb of the moon is perfect; and the reading off of the limb at the index will be the observed distance between the moon's enlightened limb and the star.

The contact of the limbs must always be observed in the middle, between the parallel wires.

It is sometimes difficult for those not much accustomed to observations of this kind, to find the reflected image in the horizon-glass; it will perhaps, in this case, be found more convenient to look directly to the object, and, by moving the index, to make its image coincide with that seen directly.

VOL. XVI.

SECT. II.—OF THE CORRECTIONS TO BE APPLIED TO OBSERVED ALTITUDES AND DISTANCES.

Observation Instruments.

1. Parallax.

In order that the place of a heavenly body may be fixed in space, it is necessary to suppose that all observations are taken from one point. This point is the centre of the earth. Consequently the places of the sun, moon, and planets, whose distances from the earth are measurable, as observed, must be reduced to what they would be if seen from the centre. The correction for this object is called parallax. The fixed stars are at so great a distance from the earth that they have no sensible parallax, and this correction is not to be applied to them.

Let C (fig. 47) be the centre of the earth, P the place of the observer on its surface, and Z his zenith; and let S be a heavenly body whose position is observed. Then ZPS is the observed zenith distance, or complement of the observed altitude, and ZCS the true zenith distance, —i.e., the zenith distance as observed at the earth's centre.

Then clearly the angle ZPS is greater than the angle ZCS by the angle PSC, which is also in the plane of the vertical circle through S. It is evident from the figure that a heavenly body is depressed by parallax; and the observed altitude is less than the true altitude by a certain amount depending on the altitude, which is called the correction of parallax.

The correction of parallax, therefore, must always be applied with the positive sign. Its amount may be easily found; for, let $\angle ZPS = z'$, and $ZCS = z$, and PSC the parallax = p ; then, in triangle PSC,

$$\sin PSC = \frac{PC}{SC} \sin SPC = \frac{PC}{SC} \sin SPZ.$$

Let $PC = r$, the radius of the earth, and $SC = R$, the distance of the heavenly body from C; also PSC is always very small, and $\sin PSC = PSC = p$ very nearly.

$$\text{Hence } p = \frac{r}{R} \sin z'.$$

r and R being invariable, p is greatest when $z' = 90^\circ$, or when S is in the horizon. Let P be the value of p in this position; then

$$P = \frac{r}{R},$$

$$\text{and } p = P \sin z' = P \cos a',$$

if a' be the observed altitude.

This will illustrate the principle on which tables of correction for parallax for different heavenly bodies, as sun, moon, &c., for different angles of altitude, are calculated.

2. Refraction.

Refraction is a correction to be applied in consequence of the rays from every heavenly body being bent or refracted as they pass through the successive layers of the earth's atmosphere, in consequence of which they describe curvilinear paths, having their convexity turned towards the zenith of the observer. The tangent to this curve at the eye of the observer is the direction in which he sees the object, and is evidently, from what has been said, bent towards the zenith. Hence the effect of refraction is to raise the heavenly bodies in the heavens above their true

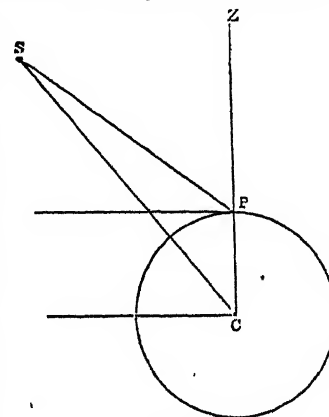

Fig. 47.

Observation Instruments. places; and the correction must therefore be applied to the observed altitudes of all bodies with a negative sign.

The law which this correction follows is very complex; it is very great when the body is near the horizon, and vanishes when it is in the zenith. The best position of heavenly bodies for observation, so far as this correction is concerned, is near the zenith.

A table of this correction for every 5' of altitude is calculated, and is to be found in all nautical tables.

3. Correction for Semidiameter.

When the sun or moon, or a planet, is observed, the altitude of one of the limbs is the observed altitude, the altitude of the centre must be obtained by adding or subtracting the semidiameter of the observed body according as the lower or upper limb is observed. The semidiameters of the sun and moon are continually changing; and tables are given in the *Nautical Almanac* of their values at noon of every day at Greenwich, and in the case of the moon at midnight also. Their values at any intermediate hour may be calculated from these, as will be more fully shown hereafter.

This correction is not to be applied when a fixed star is the object observed.

4. Correction for Dip.

The altitude is supposed to be observed from the true horizon—i.e., from a horizontal plane through the place of the observer. This, however, is never the case, for the observer's eye must then be on the earth's surface. It is, in fact, always elevated above it, and the apparent horizon is depressed in consequence below the true horizon.

The nature of this correction will be easily seen from

fig. 48. B the place of observation at a distance $AB = d$ feet above the surface, BH' touching the surface at H' ; then BH' is the plane of the sensible horizon; S a heavenly body to be observed. Draw Bh parallel to AH , the true horizon of A, and let BH' and AH intersect in J. Then, since AB is very small compared with BS and AS , the $\angle ABS$ may be considered as equal to HAS . Also let R = earth's radius, CA or CH' . Hence observed altitude of S

$$= H'BS = \angle BS + \angle BH'$$

$$= \angle BS + \angle JBS = \angle BS + \angle ACH'.$$

Or true altitude = observed altitude - $\angle ACH'$.

$$\text{Now } \tan \angle ACH' = \frac{BH'}{CH'} = \frac{\sqrt{(2R+d)d}}{R}$$

$$= \sqrt{\frac{2d}{R}} \text{ nearly, because } \frac{d^2}{R^2} \text{ may be neglected in comparison of } \frac{d}{R}.$$

$$\text{Also } \angle ACH' = \tan \angle ACH' \text{ nearly;}$$

$$\therefore \angle ACH' = \sqrt{\frac{2d}{R}}$$

$$\text{Now } R \text{ in feet} = 6120 \times 3958.$$

Hence $\angle ACH'$ in seconds

$$= 57.29577 \times 60 \times 60 \times \sqrt{\frac{2d}{6120 \times 3958}}$$

Hence, putting $d = 1, 2, 3, \&c.$, feet respectively, we can find the dip when the eye is 1, 2, 3, $\&c.$, feet respectively above the surface.

Whence tables for the dip at different elevations may be calculated.

5. Index Error.

This error has already been explained.

It will be observed that all observed altitudes are affected with *refraction* and *dip*, of which the first is always subtractive, and the second is subtractive in all observations, except when the back horizon-glass of the quadrant is made use of, when it is additive.

Parallax and semidiameter affect only those bodies whose distance from the earth is not very great, and which have a sensible diameter, as the sun and moon; but no fixed stars. Parallax is always additive; and the semidiameter is to be added or subtracted according as the lower or upper limb of the heavenly body is observed.

CHAP. II.—PRELIMINARY PROBLEMS IN NAUTICAL ASTRONOMY, AND USE OF NAUTICAL ALMANAC AND TABLES.

SECT. I.—OF TIME.

A day is the interval between two successive transits of a heavenly body over the meridian, and derives its name from the body whose motion is observed; and of whatever denomination it be, it is divided into 24 hours, each hour into 60 minutes, and each minute into 60 seconds. The interval between two successive transits of the sun is a solar day; of the moon, a lunar day; of a fixed star, a sidereal day. The earth's revolution about her axis is performed always in the same time; hence if all the heavenly bodies retained the same position with regard to one another, all days of whatever name would be of the same length. The sun (or, more strictly speaking, the earth), the moon, and planets are always varying their position with respect to one another and the fixed stars; and they move with velocities not only different from each other, but variable in different parts of their own orbits. The length of the day, therefore, determined by these bodies is variable. In order to obtain a definite and uniform measure of time, the *mean solar day*, which is the average of all the apparent solar days in the year, is employed. An imaginary body, called the *mean sun*, is supposed to describe the equator uniformly with the true sun's average or mean daily motion, and the interval between two successive transits of this imaginary sun is a *mean solar day*.

Clocks and chronometers are adapted to mean solar time; so that a complete revolution through twenty-four hours of the hour-hand of one of these instruments would exactly correspond with the revolution of the earth about her axis with regard to the mean sun. Time reckoned in mean solar days and parts of mean solar days is called *mean solar time*.

The true sun sometimes passes the meridian before and sometimes after the mean sun; the difference in time of the transits of the true and mean suns is called the *equation of time*, and is sometimes to be added and sometimes to be subtracted from the one of these times to obtain the other, as is pointed out in the *Nautical Almanac*.

As the earth revolves about her axis from E. to W., different meridians successively come under the mean sun; and since, after the lapse of twenty-four mean solar hours,

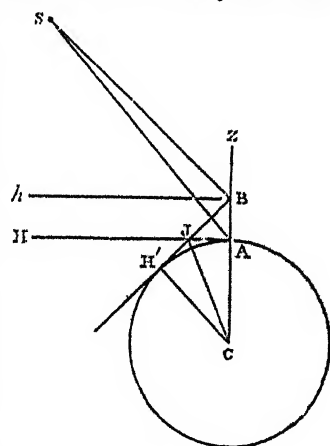

Fig. 48.

Nautical Astronomy the same meridian again comes under the sun; it follows that for every 15° of longitude between the places, there is a difference of 1^h of mean time; and that mean noon is 1^h earlier for every 15° of E. longitude, and 1^h later for every 15° of W. longitude.

A sidereal day is the interval between two successive transits over the same meridian of the vernal equinox, or the first point of Aries. This is not strictly a uniform measure because of the change of the position of this point of Aries in consequence of precession and nutation. Time, therefore, so reckoned, ought strictly to be called apparent sidereal time; and *mean sidereal time* to be reckoned from the transit not of the true but of the mean equinoctial point. The smallness of the fluctuations to which a clock regulated to *apparent* sidereal time, compared with one regulated to *mean* sidereal time, is subject, amounting at the utmost to $2^s.3$ in 19 years, has prevented the practical inconvenience of this being felt; no clock being sufficiently perfect to go for so long a period without requiring frequently to be re-adjusted.

The sun's apparent revolution in his orbit round the earth takes place in 365.242218 mean solar days; the mean sun, therefore, describes an angle of $59' 8''.33$ in a mean solar day; hence, in the interval between two successive transits of the mean sun over the same meridian, the earth revolves through $360^\circ 59' 8''.33$; but in a sidereal day the earth revolves through 360° . Whence we obtain the proportion—

A sidereal day: a mean solar day :: $360^\circ : 360^\circ 59' 8''.33$.

Whence also it is evident that, if the same interval of absolute time be expressed in *mean solar* and also in *sidereal time*, it will be greater in the latter denomination than in the former.

Tables are calculated for the *acceleration* of sidereal on *mean solar* time, and, conversely, for the *retardation* of mean solar on *sidereal* time, which are useful for converting intervals of sidereal into mean solar time, and conversely. These are to be found at page 516 of the *Nautical Almanac*.

Astronomical mean time always begins at noon, and goes on to the succeeding noon through 24 hours; so that a clock which shows astronomical mean time, set for any place (as Greenwich), shows $0^h 0^m 0^s$ when the mean sun is on the meridian, and shows 24 hours, or $0^h 0^m 0^s$, when the mean sun is again on the meridian.

A clock set to show sidereal time shows $0^h 0^m 0^s$ when the mean equinoctial point is on the meridian, and shows 24 hours, or $0^h 0^m 0^s$, again when this point is next on the meridian.

Sidereal Time, in the *Nautical Almanac*, is the sidereal time at mean noon for the meridian of Greenwich; or, in other words, the hour angle of the equinoctial point when the mean sun is on this meridian; and is very useful in all cases where mean time is to be deduced from observations of heavenly bodies.

The civil day is reckoned from midnight to midnight, and is divided into 12 hours, from midnight to noon, called A.M.; and into 12 hours, from noon to midnight, called P.M. Evidently time P.M., and astronomical mean time up to midnight, are the same. But for time A.M., add 12 hours, and date the day one back.

Thus, June 3, $7^h 5^m 27^s$ P.M. is, June 3, $7^h 5^m 27^s$ astronomical time; but, June 3, $5^h 12^m 37^s$ A.M. is, June 2, $17^h 12^m 37^s$ A.M.

Conversely, if the astronomical time is given, and the corresponding civil time is required, if under 12 hours, the given time is the same time P.M. for the same date; if above 12 hours, subtract 12 hours from it, and date the day one forward, and the result is civil time A.M.

Thus, September 18, $7^h 10^m 15^s$ is, September 18,

$7^h 10^m 15^s$ P.M.; but September 18, $22^h 13^m 45^s$ astronomical is, September 19, $10^h 13^m 45^s$ A.M.

Nautical Astronomy

PROB. 1.—To convert degrees, or parts of the equator, into time.

Rule.—Divide the degrees by 15; the result gives hours. Multiply the remaining degrees, if any, by 4; the result is minutes. Divide the number of minutes by 15 for minutes, and then multiply the remaining minutes by 4 for seconds. Divide the seconds by 15 for seconds, and decimals of seconds, if necessary.

Ex. 1.—Reduce $26^\circ 45'$ to time.

Divide 26 by 15, the quotient is 1, with remainder 11. Hence, by the rule—

$$\begin{array}{r} 26^\circ = 1^h 44^m \\ 45' = 0 \quad 3 \\ \text{or } 26^\circ 45' = 1^h 47'. \end{array}$$

Ex. 2.—Reduce $139^\circ 48' 18''$ to time.

$$\begin{array}{r} 139^\circ = 9^h 16^m 0^s \\ 48' = 0 \quad 3 \quad 12 \\ 18'' = 0 \quad 0 \quad 1.2 \\ \text{or } 139^\circ 48' 18'' = 9^h 19^m 13.2^s. \end{array}$$

PROB. 2.—To convert time into degrees, minutes, and seconds.

Rule.—Multiply the given time by 10, and add to the result half of the product. The result will be the corresponding degrees, minutes, and seconds.

Ex.—Convert $3^h 4^m 28^s$ into degrees, &c.

$$\begin{array}{r} 3^h 4^m 28^s \\ \quad \quad \quad 10 \\ \hline 30 \quad 44 \quad 40 \\ \text{One half} = 15 \quad 22 \quad 20 \\ \hline 45 \quad 7 \quad 0 \\ \text{Answer} \dots\dots\dots 46^\circ 7'. \end{array}$$

PROB. 3.—Given the time under any known meridian, to find the corresponding time at Greenwich.

Rule.—Let the given time be reckoned from the preceding noon to turn it into astronomical time; convert the longitude of the known meridian into time, which add to the given time if the place be W. of Greenwich, and subtract from the given time if it be E.; and, if necessary, increase the time by 24 hours, reckoning the day one back. If the resulting time exceed 24 hours, put the date one day forward, and subtract 24 hours.

Ex. 1.—It is $6^h 15^m$ P.M., June 23, in a ship whose longitude is $76^\circ 45'$ W.

$$\begin{array}{r} 76^\circ 45' = 5^h 7^m. \\ \text{Given time, June 23} \dots\dots\dots 6^h 15^m \\ \text{Longitude} \dots\dots\dots 5 \quad 7 \quad \text{W.} \\ \hline \text{Time at Greenwich} \dots\dots\dots 11 \quad 22 \quad \text{June 23.} \end{array}$$

Ex. 2.—The time at a ship in longitude $139^\circ 48' 15''$ E. is, July 24, $5^h 25^m 20^s$ P.M.; required the Greenwich time.

$$\begin{array}{r} 139^\circ = 9^h 16^m 0^s \\ 48' = 0 \quad 3 \quad 12 \\ 15'' = 0 \quad 0 \quad 1 \\ \hline 9 \quad 19 \quad 13 \end{array}$$

This being greater than the given time, we next add 24^h to the latter, and we have—

$$\begin{array}{r} 20^h 25^m 20^s \\ \quad \quad \quad 9 \quad 19 \quad 13 \\ \hline \text{Time at Greenwich} \dots\dots\dots 29 \quad 44 \quad 33 \quad \text{July 23.} \\ \text{Or civil time} \dots\dots\dots 8 \quad 6 \quad 7 \quad \text{A.M. July 24.} \end{array}$$

Ex. 3.—The time at a ship in longitude $175^\circ 45'$ W. is, June 28, $4^h 18^m 12^s$ A.M.; what is the Greenwich time?

$$\begin{array}{r} 175^\circ = 11^h 40^m \\ 45' = 0 \quad 3 \\ \hline \text{Longitude} = 11 \quad 43 \quad \text{W.} \end{array}$$

$$\begin{array}{r} \text{Time at ship is, June 27} \dots\dots\dots 16^h 18^m 12^s \\ \text{Longitude} \dots\dots\dots 11 \quad 43 \quad 0 \quad \text{W.} \\ \hline \text{Time} \dots\dots\dots 28 \quad 1 \quad 12 \quad \text{June 27.} \\ \text{Or} \dots\dots\dots 4 \quad 1 \quad 12 \quad \text{June 28.} \end{array}$$

Nautical
Astronomy

Ex. 4.—The time at a ship in longitude 178° E. is, October 14, $3^h 15^m$ A.M.; what is the time at Greenwich?
 $3^h 15^m$ A.M. on Oct. 14... = Oct. 13, $15^h 15^m 0^s$
 Longitude 178° = $11^h 52^m 0^s$ E.
 Time at Greenwich. = Oct. 13, $3^h 23^m 0^s$

PROB. 4.—To find the Greenwich time by a chronometer whose error on Greenwich mean time is known.

Rule.—Add or subtract the error of the chronometer to the time shown by it, according as it is slow or fast; the result is Greenwich time. Sometimes 12 hours must be added to this result, and the day reckoned one back. The best way to obviate this error, is to obtain Greenwich time approximately, by Problem 3, by help of the ship's mean time and longitude by account; if the difference between the two (Greenwich) dates, so found in these two ways, is nearly 12 hours, then the date by chronometer must be increased by 12 hours, and the day reckoned one back if necessary, so as to make the two dates agree in the day and hour nearly.

Ex. 1.—June 15, 1857, at $7^h 45^m$ P.M. mean time nearly, in longitude 45° W., a chronometer showed $10^h 53^m 12^s$, being $3^m 15^s$ fast; required the Greenwich time.

By Chronometer.		By Rule 3.	
June 15, Chronometer	$10^h 53^m 12^s$	Ship, June 15....	$7^h 45^m$
Error on Greenwich	mean time (fast)	Longitude.....	$3^h 0^m$ W.
	0 3 15	Greenwich time, 10	45
Greenwich time	10 49 57	Greenwich time, 10	45

Ex. 2.—October 12, 1857, at $11^h 45^m$ P.M., in longitude $110^{\circ} 35'$ W., a chronometer showed $7^h 0^m 40^s$, being $9^m 5^s$ slow; required the Greenwich date.

By Chronometer.		By Rule 3.	
Oct. 12.....	$7^h 0^m 40^s$	Ship, Oct. 12.....	$11^h 45^m 0^s$
Error (slow).....	0 9 5	Longitude	$7^h 22^m 20^s$
	7 9 45	Greenw., Oct. 12...	$19^h 7^m 20^s$
	12 0 0		
Greenwich, Oct. 12, 19	9 45		

PROB. 5.—Given the Greenwich date, to find the date under a given meridian.

Rule.—The Greenwich date being reduced to the preceding noon, reduce the longitude to time, and subtract it from Greenwich date, increased by 24 hours, and put one day back if necessary, if the longitude be W.; and add if the longitude be E.

Ex. 1.—An eclipse of the moon commenced at Greenwich, December 25, 1852, at $22^h 14^m 36^s$; at what time did it begin at a place in longitude 175° E.?

Greenwich time, Dec. 25.....	$22^h 14^m 36^s$
Longitude.....	$11^h 40^m$ E.
	33 54

(i.e.) December 26..... 0 54

Ex. 2.—On the 6th of December 1857, at 9^h at Greenwich, the distance of the moon from the sun was $106^{\circ} 44' 34''$; at what time will the distance be the same in longitude $166^{\circ} 15' 43''$ W.?

Long. = $11^h 13^m 2^s 86$ W.	Greenwich, Dec. 5.....	$33^h 0^m 0^s$
Add 24 to Greenwich time.	Longitude.....	$11^h 13^m 2^s 86$ W.
Date required, Dec. 5.....		$21^h 46^m 57^s 14$.

SECT. II.—OF THE SUN'S DECLINATION, RIGHT ASCENSION, EQUATION OF TIME, AND SEMIDIAMETER AND SIDEREAL TIME.

All of these quantities are given in the *Nautical Almanac* for the noon of every day. They all vary, and consequently their value at any time intermediate between two successive noons is different from that at either noon. For ordinary purposes, it is sufficient to suppose that the change of these quantities is proportional to the time from the preceding noon. Hence, if the difference of the value between the preceding and succeeding noon is taken from the *Nautical Almanac*, a simple proportion will give the quan-

tity to be applied to the value at the preceding noon, which must be added if the quantity is increasing, and subtracted if it be decreasing. As the values of the quantities are given for Greenwich noon, it is necessary to reduce the ship's time to Greenwich time, in order to obtain their proper value.

This process may be materially shortened by the use of proportional logarithms, which are given in nautical tables, and to which the reader is referred for an explanation. For example, to take out the sun's declination at a given time in a given place, get a Greenwich date, as already explained; take out from the *Nautical Almanac* the declination at two successive noons between which the date lies; take their difference; take out from the tables the logarithm of the Greenwich date of the sun; add to it the proportional logarithm for the change in 24 hours:—the result is the proportional logarithm of the change of declination for the given time. This will be found from the table, and added or subtracted, according as the declination is increasing or decreasing. Sometimes the declination at two successive noons will be of different names; the difference must then be found by adding them.

The very same mode applies to finding the equation of time, and also the sun's apparent right ascension.

The sun's semidiameter may always be taken to be that corresponding to the nearest noon.

The right ascension of the mean sun, called in the *Nautical Almanac* the *sidereal time*, may be found for any other meridian than Greenwich in the same way. Since, however, the motion of the mean sun is uniform throughout the year, the change in any given number of hours, minutes, and seconds is the same for all days, and can be found at once from the "Table of Time Equivalents" given in the *Nautical Almanac*.

Opposite to each of these quantities in the *Nautical Almanac* is given the difference for one hour, which enables us to find the quantity for any other hour than noon, by multiplying this hourly difference by the number of hours in the date from noon, and adding to it the proportional parts for the additional minutes and seconds, and applying this difference to the value for the preceding noon, with a positive or negative sign, according as the quantity is increasing or decreasing.

The following examples will illustrate these directions:—

Ex. 1.—October 11, 1857, in Long. $36^{\circ} 45'$ E., at $7^h 45^m$ A.M.; required the sun's declination, right ascension, equation of time, and sidereal time, i.e., the right ascension of the mean sun when crossing the meridian of observer.

October 11, $7^h 45^m$ A.M. civil is, October 10...	$19^h 45^m$

Gives, as before 6' 33"-5 N.

SECT. III.—OF TAKING OUT MOON'S DECLINATION, RIGHT ASCENSION, SEMIDIAMETER, AND HORIZONTAL PARALLAX.

The moon's declination and right ascension are given for every hour in the *Nautical Almanac*; and the difference for 10^m at the beginning of every hour is recorded. From these data, the moon's declination and right ascension at any hour can be readily obtained; for by multiplying the difference for 10^m by the number of intervals of 10^m in the given time since the last hour, and taking parts for the additional minutes and seconds, and adding the result if the declination be increasing, and subtracting if decreasing, to the declination at the last preceding hour, we shall find the declination. The difference must always be added to the right ascension. Or they may be found by a table of logistic logarithms: thus, add together the logistic logarithms of the minutes and seconds in the Greenwich date, and the proportional logarithms of the difference; the result will be the proportional logarithm of the correction to be applied.

The moon's semidiameter and horizontal parallax are given in the *Nautical Almanac* for every 12^h,—viz., from mean noon to mean midnight, and mean midnight to mean noon, of every day at Greenwich. Hence we may proceed as for the sun's right ascension and declination, except that we must always take out of the table the declination or right ascension for the mean noon or mean midnight, according as the time lies between noon and midnight or midnight and noon; and if the Greenwich date exceed 12^h, we must subtract 12^h from it, and reckon the difference from the preceding midnight.

Ex. 1.—August 10, 1857, in Long. 84° 30' E., at 7^h 44^m 15^s P.M.; required the moon's right ascension and declination.

3 ^h is $\frac{1}{4}$ 3.5	
30 ^m is $\frac{1}{2}$58	
	4.08

Or the correction is 4".

And for semidiameter—

Difference for 12 ^h 3".7	
3 ^h is $\frac{1}{4}$92	
30 ^m is $\frac{1}{2}$15	
	1.07

Or the correction is 1".07.

SECT. IV.—OF LUNAR DISTANCES.

PROB.—Having given a lunar distance, to find its Greenwich date.

Rule.—Lunar distances are found for every third hour of Greenwich mean time, and are recorded in the *Nautical Almanac*, as also the proportional logarithms of the differences of the distances at intervals of every three hours. To find, then, the Greenwich date corresponding to a given distance, find in the table the *nearest* distance preceding in order of time the given distance, and take the difference between it and the given distance; from the proportional logarithm of this difference subtract the proportional logarithm of the said nearest distance; the remainder will be the proportional logarithm of the correction to be applied to the Greenwich date answering to the nearest distance in order to obtain the approximate Greenwich time.

The distances are here supposed to increase uniformly, which is not the case. It is therefore necessary to apply a correction to the time above obtained, if great accuracy is required. This may be found by help of a "Table showing the Corrections required on account of Second Differences," in the *Nautical Almanac*, as follows:—(1.) Find the approximate interval by the preceding rule. (2.) Take the difference between the proportional logarithms which stand opposite to the distances which include the given distance. (3.) Look down the column in the table at the head of which is this difference of proportional logarithms, and along the column at the left hand side of which stands the approximate interval; the number so found is the correction, which is to be added to the approximate time if the proportional logarithms are decreasing, and subtracted if they are increasing.

Ex.—Required the time at Greenwich at which the *reduced* distance of the moon from Jupiter will be 42° 55' 18" on the 23d December 1857.

From the table, it appears this will be between noon and 3^h. The *nearest* distance preceding therefore is,—

Distance at noon 43° 58' 19"	Propor. log.2590
Reduced distance 42 55 18	
Difference 1 3 1	Propor. log.4558
Approximate interval 1 ^h 54 ^m 24 ^s	"1968

The difference of proportional logarithms at noon and 3^h is 12; and on looking in the table for second differences down the column headed ("), and along the column on the left of which is 2^h, the

nearest to the approximate interval, we find 3" the correction, which is to be added, as the proportional logarithms are decreasing. Hence the Greenwich time is 1^h 54^m 27^s.

SECT. V.—OF MEAN AND APPARENT SOLAR TIME, AND SIDEREAL TIME.

PROB. 1.—Given mean solar time at any given place, to find apparent solar time; and, conversely, given apparent, to find mean solar time.

Find the time at Greenwich, and correct the equation of time for this date. The equation of time so corrected applied to the given time, with the proper sign (as shown in the *Nautical Almanac*), will give the time required.

Ex. 1.—June 16, 1857, mean solar time 8^h 15^m P.M., in longitude 25° W.; to find the apparent time.

Ship, June 16	8 ^h 15 ^m
Longitude	1 40 W.
Greenwich, June 16	9 55

Equation of time (p. 11, *Nautical Almanac*) subtractive

June 16	19 ^m 43

	12.796

Or 12^m 8^s nearly.

Hence mean time at ship, 6^h 50^m 47^s 2 P.M., Oct. 15.

PROB. 2.—Given solar time, to find sidereal time.

Rule.—If the given time be *mean solar*, find the Greenwich date; correct the right ascension of mean sun for this date, and add to the mean time at ship; the result is sidereal time.

If the given time is *apparent solar*, convert it into mean solar time, as in Problem 1, and proceed as before.

Ex.—Nov. 18, 1857, at 9^h 35^m 30^s A.M., mean time, in Long. 18° 7' W.; required the sidereal time.

Ship, Nov. 17	21 ^h 35 ^m 30 ^s
Longitude	1 12 28 W.

Greenwich, Nov. 17th

Right ascension of mean sun, Nov. 17

Correction for 22^h

" 47^m

" 58^s

Right ascension of mean sun

Ship mean time

Sidereal time

Rejecting 24^h in the result.

Nautical
Astronomy

By help of the last problem, we may find what bright stars in the catalogue of the *Nautical Almanac* will be on the meridian of a given place next after any time, mean or apparent.

For, having found the sidereal time at a ship, it is evident that the star whose right ascension is next greater, is the first that will pass the meridian in question.

It is sometimes required to find all the bright stars that will pass a given meridian between two specified hours. We must in that case find the sidereal time for both hours, and all the bright stars in the catalogue whose right ascensions lie between these limits will pass the given meridian between the specified hours.

Ex. 1.—To find what bright star will pass the meridian in Long. $18^{\circ} 7' W.$, on November 18, 1857; next after $9^h 35^m 30^s A.M.$ (See Example to Problem 2.)

Looking in the catalogue of bright stars in the *Nautical Almanac*, we find that the bright star whose right ascension is the next greater than $13^h 25^m 12^s.44$, is β Corvi, which is the star required.

Ex. 2.—What bright stars in the *Nautical Almanac* passed the meridian of a place in Long. $64^{\circ} E.$, between the hours of 6 and 9, on March 10, 1857?

Ship, March 10.....	6 ^h 0 ^m 0 ^s	9 ^h 0 ^m 0 ^s
Longitude.....	4 16 0 E.	4 16 0 E.
Greenwich, March 10.....	1 44 0	4 44 0

(1.) Right ascension of mean sun—

Greenwich, March 10.....	23 ^h 12 ^m 25 ^s .64
Correction for 1 ^h 0 ^m	0 0 9.8565
„ 0 44.....	0 0 7.2281
	23 12 42.726

Ship, March 10.....	6 0 0
Sidereal time.....	5 12 42.7246 (1.)

(2.) Right ascension of mean sun—

Greenwich, March 10.....	23 ^h 12 ^m 25 ^s .64
Correction for 4 ^h 0 ^m	0 0 39.4259
„ 0 44.....	0 0 7.2281
	23 13 12.2940

Ship.....	9
Sidereal time.....	8 13 12.2940 (11.)

On looking at the catalogue, we find that the stars whose right ascensions lie between these limits are from β Tauri to 15 Argus, which are the stars required.

PROB. 3.—Given sidereal, to find mean solar time.

Rule.—Take out of the *Nautical Almanac* the right ascension of the mean sun for noon of the given day. Subtract this from the sidereal time, increased, if necessary, by 24 hours; the remainder is mean time nearly. By help of the table which gives the relation of mean solar and sidereal time already referred to, correct this approximate time, and the result will be the mean time required.

Ex.—July 21, 1857, when a sidereal clock showed $6^h 45^m 35^s$ find the mean time.

Sidereal time.....	6 ^h 45 ^m 35 ^s
Right ascension mean sun at mean noon.....	7 56 47.66
Mean time nearly.....	22 48 47.34
Correction for 22 ^h	3 ^m 46 ^s .69
„ 48 ^m	0 7.88
„ 47 ^s	0 0.13
Mean time.....	0 3 54.60
	22 44 52.74

By means of the above we can find the error of a clock or chronometer by comparing the time shown by it with that of a sidereal clock in an observatory. Thus, Greenwich, November 4, 1857, a sidereal clock showed $18^h 15^m 30^s$, and a chronometer showed $3^h 28^m 15^s$, the sidereal clock being $3^m 13^s.5$ slow; required the error of the chronometer.

Sidereal clock.....	18 ^h 15 ^m 30 ^s
Error (slow).....	0 3 13.5
Sidereal time.....	18 18 43.5
R. ascen. of mean sun at mean noon.....	14 54 42.49
Mean time nearly.....	3 24 1.01
Correction for 3 ^h	29 ^s .57
„ 24 ^m	3.94
„ 1 ^s	0
Mean time.....	0 0 33.51
Chronometer.....	3 28 27.50
Error (fast).....	0 4 48.5

Nautical
Astronomy

PROB. 4.—To find at what time any heavenly body will pass the meridian of a given place on a given day.

Rule.—From the right ascension of the given star taken out of the *Nautical Almanac*, increased, if necessary, by 24 hours, subtract the right ascension of the mean sun at mean noon (or *sidereal time*, as it is called in the *Nautical Almanac*). This gives the mean time at the ship approximately. Apply the longitude to this, and thus get a Greenwich date, and by this date correct the right ascension of the mean sun, and subtract the quantity so found from the star's right ascension; this will be the time required.

Ex.—At what time will β Corvi pass the meridian of a place in Long. $62^{\circ} 20' E.$, on July 24, 1857?

Right ascension β Corvi, July 24.....	12 ^h 26 ^m 53 ^s .88
Right ascension of mean sun at mean noon (sidereal time, <i>Naut. Almanac</i>).....	8 8 37.33
Sidereal time ship, approximate.....	4 18 16.55
Longitude.....	4 9 20.0 E.
Greenwich date, July 24.....	0 ^h 8 ^m 56 ^s .55
Right ascension of mean sun at mean noon.....	8 8 37.33
Correction for 8 ^m	0 0 1.31
„ 56 ^s	0 0 0.15
Right ascension of mean sun ...	8 8 38.79
„ β Corvi.....	12 26 53.88
Time of star's passing the meridian.....	4 18 15.09

SECT. VI.—OF THE MOON'S AUGMENTATION—CORRECTION OF SEMIDIAMETER ON ACCOUNT OF REFRACTION—THE MOON'S MERIDIAN PASSAGE, &c., &c.

1. *Of the Moon's Augmentation.*—The moon's semidiameter given in the *Nautical Almanac* is calculated as if seen from the earth's centre. Moreover, on account of the comparatively moderate distance of the moon from the earth, the moon's semidiameter subtends an angle at the earth's surface which sensibly varies with the altitude, being greatest when the moon is in the zenith, and least when in the horizon of the observer. The correction to be applied to the semidiameter from this cause is called the augmentation. It is computed for every degree of altitude, and is to be found in all nautical tables.

2. *Contraction of Moon's Semidiameter on account of Refraction.*—The correction for refraction varies very rapidly near the horizon, and consequently the moon's lower limb is sensibly more raised than the upper; and the moon's apparent form is that of an ellipse instead of a circle. Hence, in taking a lunar distance when the moon is near the horizon, the moon's semidiameter to be added to the observed distance, as taken from the tables, is greater than it ought to be; and a correction must be applied in consequence of the moon's diameter being an oblique diameter of the elliptic face, and not the horizontal or greatest diameter. This correction is always subtractive, and is given in nautical tables.

3. *Of the Moon's Meridian Passage.*—In west longitude the moon crosses the meridian later with regard to the sun than at Greenwich, and in east longitude earlier; because the moon's distance from the sun in right ascension is constantly changing. Hence to the Greenwich meridian passage of the moon must be applied a correction for every other place, depending on the longitude. All nautical tables contain this correction.

The corrections to be applied to the observed altitudes and distances of the heavenly bodies have been now sufficiently explained, and the reader will, with a little experience, easily understand how the several corrections are to be taken out of the tables. Index error, dip, and refraction are common to all observed altitudes, and must be applied in the order in which they are here set down. If the body observed be a star, this is all that is required.

Finding
the Latitude.

If a planet, the parallax for the given altitude, taken from the proper table, must be added. If the observed body be the sun, after the dip apply the sun's semidiameter, and then correct for refraction and parallax. These two corrections are frequently given together, under the name of *correction in altitude*, which is always subtractive, because the refraction is always greater than the parallax. If the observed body be the moon, the semidiameter and horizontal parallax cannot be considered as invariable for 24 hours; they must therefore be corrected for the proper Greenwich date, as already pointed out. To the semidiameter thus corrected must be added the augmentation, from the proper table: The rest of the process is exactly the same as for the sun.

Ex. 1.—Feb. 1, 1857, at 2^h 40^m P.M., in Lat. 53° 20' N., and Long. 13° 20' E., the observed altitude of the sun's lower limb was 13° 35', the index error was +1' 20", and the height of the eye above the sea 18 feet; to find the sun's true altitude.

Observed altitude.....	13° 35' 0"
Index correction	+ 0 1 20
	13 36 20
Dip	- 0 3 33
	13 32 47
Sun's apparent diameter	+ 0 16 15
Apparent altitude.....	13 49 12
Correction in altitude	0 3 45
Sun's true altitude	13 45 17

Ex. 2.—August 24, 1857, in Long. 18° 20' W., the observed meridian altitude of the moon's lower limb was 54° 30' 20", the index correction was + 2' 20", and height of the eye above the sea 20 feet; required the moon's true altitude.

August 24. Time at ship	0 ^h 0 ^m 0 ^s
Longitude	1 13 20 W.
Greenwich date, August 24	1 13 20
Moon's semidiameter, 24th, Noon.....	14' 54".4
Midnight.....	14 52.0
	0 2.4

CHAP. III.—ON FINDING THE LATITUDE.

SECT. I.—OF FINDING THE LATITUDE BY MERIDIAN ALTITUDES.

1. By a single Meridian Altitude above the Pole.

Subtract the true meridian altitude (corrected from observed meridian altitude) from 90°; the result is the zenith distance—which mark N. or S., according as the zenith is north or south of the observed heavenly body: find also the declination, which must be marked N. or S. If the zenith distance and the declination have the same name, their sum will be the latitude, with the name of either. If they be of different names, take their difference, which will be the latitude, with the name of the greater.

The process will differ in detail, according to the nature of the body observed.

(1.) If it be a fixed star, the altitude must be corrected only for index correction, dip, and refraction; and the declination is given at once by the tables.

(2.) If it be a planet, the declination must be corrected by getting a Greenwich date, applying the proportional increase or decrease for this date. If great accuracy is required, the semidiameter and horizontal parallax must also be found, and the altitude corrected for these.

(3.) If it be the sun, the Greenwich date must be got, and the declination corrected for this; the altitude must be corrected for index, dip, semidiameter, refraction, and parallax.

(4.) If it be the moon, a Greenwich date must be got. If it be only known that the observed altitude is a meridian altitude, the meridian passage at Greenwich must be corrected for the longitude, and the Greenwich date obtained by applying the longitude in time as already shown. The moon's semidiameter, horizontal parallax, and declination, must be corrected for the Greenwich date, and the true altitude and declination thus found. When the true altitude and declination are found, the remainder of the process is according to the rule given above, and is the same for all.

Ex. 1.—May 20, 1857, the observed meridian altitude of Castor was 49° 20' 30" (zenith N. of star), the index correction was -3' 40", and the height of the eye above the sea was 18 feet; required the latitude.

Observed altitude.....	49° 20' 30"

Latitude.....	52 3 14.6 N.

SECT. II.—BY OBSERVED ALTITUDES OUT OF THE MERIDIAN.

1. By Observations of the Altitude of the Pole-Star (a Polaris).

The tables for this purpose are given in the *Nautical Almanac*, pp. 513 to 515.

Rule.—From the observed altitude, corrected for the error of the instrument, refraction, and dip of the horizon, subtract 2'.

Reduce the mean time of observation at the place to the corresponding sidereal time.

With the sidereal time found, take out the *first correction* with its proper sign. If the sign be +, the correction must be added to the reduced altitude; but if it be -, it must be subtracted; in either case the result will give an approximate latitude.

With the altitude and sidereal time of observation, take out the *second correction*; and with the day of the month and the same sidereal time, take out the *third correction*. These two corrections, added to the approximate latitude, will give the latitude of the place.

Ex.—January 20, 1857, at 9^h 40^m P.M. (mean time nearly), in Long. 30° 20' E., the observed altitude of Polaris was 31° 40' 20", the index correction was -2' 20", and height of the eye above the sea, 10 feet; required the latitude.

3. By Observed Altitudes of a Heavenly Body very near the Meridian.

The sun is the body most usually observed for the purpose. The apparent time from noon or hour angle is supposed to be known; as also the latitude by account, which is supposed to differ from the true latitude only by a small quantity.

Rule.—Add together the tabular logs. of cosines of the latitude by account, and of the declination of the observed body. To these add log. rising, if a table of log. rising be used; or, 6.301030 + log. haversine hour angle, if a table of haversines be used; or twice the log. sine of half the hour angle with the same constant log., if a table of log. sines only be used.

In all cases cast out the tens from the result, and the remainder is the logarithm of a natural number, which, added to the natural sine of the true altitude, will give the natural cosine of the meridian zenith distance. The declination applied to this—as already pointed out in preceding problems—will give the latitude. The hour angle in this rule must be found by applying to the mean time at the ship the equation of time corrected for the Greenwich date.

If the latitude thus found differ much from the latitude by account, the work must be repeated, using the latitude found instead of latitude by account.

Ex.—October 11, 1857, in Long. 114° E., and Lat. by account 46° 10' N., the chronometer showed 4^h 38^m 10^s, being slow on Greenwich 14^m 10^s. The altitude of the sun's lower limb was observed to be 36° 35' 20", the index error was -2' 20", and the height of the eye above the sea 16 feet; required the latitude.

Finding
the Lati-
tude.

4. By two Observed Altitudes of the Sun, and the Time between; having given also the Latitude by Account (Dowse's Method).

Rule.—To find the hour angle corresponding to the greater meridian altitude—i.e., the hour from apparent noon, at which the greater altitude is observed.

To the log. secant of the latitude by account, add the log. secant of the sun's declination (the mean between the declinations at the first and second observation); this, rejecting 20, is called the logarithm ratio. To this add the log. of the difference of the natural sines of the two altitudes, and the logarithm of the half-elapsed time from the proper column (taken from nautical tables, which are furnished with special tables for this purpose).

Find this sum in the column of middle times, and take out the time answering thereto; the difference between this and the half-elapsed time will be the time from noon, when the greater altitude was observed.

Or from any table:—

Find the logarithm ratio as before.

Subtract each of the true altitudes from 90°, to get the true zenith distances, and take half their sum and half their difference; and to the logarithm ratio add the sum of the log. of the sines of this semi-sum and semi-difference, and from this sum subtract the log. sine of the half-elapsed time; the remainder is the log. sine of middle time, which find from a table of log. sines, and the difference of the middle time and half-elapsed time is the time from noon, at which the greater altitude is observed.

We have now an observed altitude and the time from noon or hour angle corresponding; the remainder of the solution is therefore the same as in the last case, except that the log. ratio, being the sum of the logarithms of the secants, may be used instead of the sum of the logarithms of the cosines, with the negative sign. If the latitude so found differs much from the latitude by account, the work must be repeated, using the computed latitude for the latitude by account.

This rule is only approximate, and must be used under the following restrictions:—1. The observations must be taken between nine in the forenoon and three in the afternoon. 2. If both the observations be made in the forenoon, or both in the afternoon, the interval must not be less than the distance of the time of observation of the greatest altitude from noon. 3. If one observation be in the forenoon and the other in the afternoon, the interval must not exceed 4½^h; and in all instances the nearer to noon the greater altitude is observed the better. 4. If the sun's meridian zenith distance be less than the latitude, the limitations are still more con-

Finding the Latitude.

tracted. If the latitude be double the meridian zenith distance, the observations must be taken between half-past nine in the morning and half-past two in the afternoon; and the interval must not exceed $3\frac{1}{2}$ h. The observations must be taken still nearer to noon if the latitude exceed the zenith distance in a greater proportion.¹

As the ship is generally in motion between the two observations, it is necessary to apply to the first altitude a correction for its run in the interval, so as to obtain what the altitude would have been if observed at the same time as the second.

If θ be the angle between the course of the ship and the bearing of the sun, the correction for run is $y = \pm m \cos \theta$, where m is the number of minutes in the angle subtended by the ship's run,—i.e., number of miles run,—and θ the angle between the bearing of the sun and the course; and the sign + or - is to be used according as the ship is moving towards or from the heavenly body: in the former case θ is less than 90° , and in the latter greater. It is evident, from the form of the expression, that this correction may be found in a traverse table by looking out the difference between the course and bearing, or what it wants of 8 points for a course, and the ship's run as a distance; the corresponding difference of latitude, multiplied by 60, will then be the number of seconds in the correction for run, which is to be added or subtracted according as the angle is less or greater than 8 points or 90° . Thus, the bearing of the sun was S.E., the run was S.S.E. 18 miles; required the correction for run. Here the angle between the bearing and the course is 2 points, and the distance 18 miles; on entering a traverse table with these, we find the true difference of latitude $16'6''$. Hence the correction for run is $+16'12''$.

Ex.—April 20, 1857, in Lat. $44^\circ 20' N.$, Long. $35^\circ 50' E.$, the following double altitude of the sun was observed:—

Mean Time, nearly.	Chronometer.	Obs. Alt. Sun's L.L.	True Bearing.
10h 40m A.M.	8h 30m 20s	$53^\circ 5' 45''$	S.E. by S.
2 40 P.M.	0 29 40	41 0 30	S.W. by W.

The run of the ship in the interval was S.S.E. 25 miles, the index correction was $-4'40''$, and the height of the eye above the sea 15 feet; required the true latitude at the last observation.

The angle between the true bearing at first observation and ship's course is 1 point; the true difference of latitude, corresponding to distance 25 and course 1 point in traverse table, is $24'5''$. Hence correction for run to be applied to the greater altitude is $+24'30''$.

Finding
the Latitude.

5. By any Two Altitudes of the same or different Heavenly Bodies, and the Polar Angle between them.

In this case the declinations of the heavenly body or bodies at the two observations are supposed to be known.

If the same body be observed at different times, the polar angle is the elapsed time measured sidereally, if necessary. If different bodies be observed at the same time, this angle is the difference of their right ascensions.

If different bodies be observed, but not at the same time, to the right ascension of the first observed body, add the elapsed time measured sidereally, and the difference between this sum and the right ascension of the second observed body is the polar angle required.

The polar angle being given, the following rule will give the latitude:—

(1.) If the sun be the body observed: from the declination find the polar distance by subtracting it from 90° , if of the same name with the latitude; and adding it, if of an opposite name.

Add together log. sine polar distance at the greater bearing, log. sine polar distance at lesser bearing, and log. haversine of polar angle; reject 10 from the index; the result is the haversine of an arc, which look out, and call arc (1).

(2.) If two stars be observed: find the polar distances; add together log. sine polar distance at greater bearing, log. sine polar distance at lesser bearing, and log. haversine of the polar angle; the result is the haversine of an arc, which find from the table, and add its versed sine to the versed sine of the difference of the polar distances; the result is the versed sine of an arc, which is arc (1), as before.

Find the difference of the polar distances, and take the difference and the sum of this quantity and of arc (1). Add together log. cosecants of the arc (1) and of polar distance at greater bearing, and the halves of the log. haversines of the two arcs just obtained; the sum, rejecting 10 in the index, is the log. haversine of an arc, which take from tables, and call arc (2).

Again, take the difference of arc (1) and the zenith distance at greater bearing, and take the sum and difference of this arc and the zenith distance at less bearing. Add together log. cosecants of arc (1) and of zenith distance at greater bearing, and the halves of the log. haversines of the arcs just found; and the result, rejecting 10 in the index, is the log. haversine of an arc, which call arc (3).

Arc (4) is the difference between arc (2) and arc (3); or the sum if the arc joining the heavenly bodies at the two observations passes between the zenith and the pole.

Add together log. sine polar distance at greater bearing, log. sine zenith distance at greater bearing, and log. haversine arc (4); the sum, rejecting 10 in the index, is the log. haversine of an arc, which call arc (5).

Add together versed sine of the difference of the zenith distance and polar distance at greater bearing, and the versed sine of arc (5). The result is the versed sine of the colatitude. Find this from the tables, subtract it from 90° ; and the result is the latitude.

This method of finding the latitude, which is at once the most general and accurate, is due to the Rev. Dr Inman, to whose excellent work on Navigation the reader is referred for further information respecting it.

Ex. 1.—March 25, 1857, in Lat. $54^\circ 47' N.$, and Long. $98^\circ E.$, the following double altitude of the sun was observed:—

Mean time, nearly.	Chronometer.	Obs. Alt. L. L.	Bearing.

CHAP. IV.—ON FINDING THE LONGITUDE BY OBSERVATION.

SECT. I.—INTRODUCTION.

The observations necessary to determine the longitude by this method are the altitudes of the sun or other heavenly body, or the distance between the sun and moon, the moon and a planet, or the moon and a fixed star near the ecliptic,

together with the altitude of each. The planets used in the *Nautical Almanac* for this purpose are the following:—Venus, Mars, Jupiter, and Saturn. The stars are, α Arietis, Aldebaran, Pollux, Regulus, Spica Virginis, Antares, α Aquilæ, Fomalhaut, and α Pegasi; and the distances of the moon's centre from the sun, and from one or more of these planets and stars, are contained in the xiii. to xviii. pages of the month, at the beginning of every third hour mean time by the meridian of Greenwich. The distance between the moon and one of these objects is observed with a sextant; and the altitudes of the objects are taken as usual with a sextant or a Hadley's quadrant.

In the practice of this method it will be found convenient to be provided with three assistants. Two of these are to take the altitudes of the sun and moon, or moon and star, at the same time that the principal observer is taking the distance between the objects; and the third assistant is to observe the time, and write down the observations. In order to obtain accuracy, it will be necessary to observe several distances, and the corresponding altitudes, the intervals of time between them being as short as possible; and the sum of each divided by the number will give the mean distance and mean altitudes; from which the time of observation at Greenwich is to be computed by the rules to be explained.

If the sun or star from which the moon's distance is observed, be at a proper distance from the meridian, the time at the ship may be inferred from the altitude observed at the same time with the distance. In this case the chronometer is not necessary; but if that object be near the meridian, the chronometer is absolutely necessary, in order to connect the observations for ascertaining the mean time at the ship and at Greenwich with each other.

An observer without any assistants may very easily take all the observations, by first taking the altitudes of the objects, then the distance, and again their altitudes, and reduce the altitudes to the time of observation of the distance; or, by a single observation of the distance, the time being known from which the altitudes of the bodies may be computed, the longitude may be determined.

A set of observations of the distance between the moon and a star or planet, and their altitudes, may be taken with accuracy during the time of the evening or morning twilight; and the observer, though not much acquainted with the stars, will not find it difficult to distinguish the star from which the moon's distance is to be observed. For the time of observation nearly, and the ship's longitude by account being known, the estimated time at Greenwich may be found; and by entering the *Nautical Almanac* with the reduced time, the distance between the moon and given star will be found nearly. Now set the index of the sextant to this distance, and hold the plane of the instrument so as to be nearly at right angles to the line joining the moon's cusps, direct the sight to the moon, and, by giving the sextant a slow vibratory motion, the axis of which being that of vision, the star, which is usually one of the brightest in that part of the heavens, will be seen in the transparent part of the horizon-glass.

SECT. II.—TO FIND MEAN TIME BY A SINGLE OBSERVATION OF THE SUN OR MOON, OR OTHER HEAVENLY BODY.

PROB. 1.—Given the latitude of a place, the altitude, and declination of the sun, to find the true time and the error of the chronometer.

Rule.—If the latitude and declination are of different signs, take their sum; otherwise take their difference. From the natural cosine of this sum or difference, take the natural sine of the altitude (corrected); find the logarithm of the remainder, and to it add the log. secants of the lati-

Finding
the Longi-
tude.

Finding the Longitude. tude and declination; the sum will be the log. rising of the horary distance of the sun from the meridian, and hence the apparent time will be known; by applying to it the equation of time, the mean time may be found, and the error of the chronometer.

Or, if a table of log. haversines be used, take the difference or sum of the latitude and declination as before. Under this difference place the zenith distance of the sun, and take their sum and difference.

Take the sum of half of the log. haversines of these quantities and of the log. secants of the latitude and declination; the result, rejecting the tens, is the log. haversine of the hour angle.

Or, if a table of sines only be used, add together one-half of the log. sines of half the arcs above found, of the log. secants of latitude and declination; the result is the log. sine of one-half the hour angle.

Ex.—March 25, 1857, at 3^h 30^m P.M. nearly, in Lat. 53° N., and Long. 35° 20' W., when a chronometer showed 5^h 46^m 20^s, the observed altitude of the sun's lower limb was 23° 12' 10", and the index correction was -4' 20", and the height of the eye above the sea 20 feet; required the true time, and error of chronometer.

By taking another observation at the interval of a few days, the daily rate of the chronometer may be found.

PROB. 2.—Given the latitude of a place, and the altitude of a known fixed star, to find the mean time of observation and error of chronometer.

The right ascension of the mean sun or sidereal time must be corrected for the Greenwich date of observation. The star's hour angle must then be found as in the last problem. To the hour angle thus found add the star's right ascension, and from the sum (increased, if necessary, by twenty-four hours) subtract the right ascension of the mean sun; the remainder is the mean time at the place at the instant of observation.

Ex.—January 16, 1857, at 8^h P.M. (mean time, nearly), in Lat. 49° 57' N., and Long. 32° 10' W., when a chronometer showed 10^h 23^m 30^s, the observed altitude of Regulus E. of meridian was 8° 20' 30", the index correction was -5' 20", and the height of the eye above the sea, 20 feet; required the mean time, and error of chronometer on Greenwich mean time.

SECT. III.—TO FIND THE LONGITUDE BY MEANS OF A CHRONOMETER.

In order to find the longitude at sea by means of a chronometer, its daily rate in mean solar or sidereal time must be established by observations made at some particular place, and its error ascertained for the meridian of that or any other known place.

An observatory is the most proper and convenient place for this purpose, as there the rate and error may be both determined with the utmost accuracy by equal altitudes, or transits over the meridian of the sun or stars. But if an observatory is not adjacent, the rate and error of the chronometer may be found by altitudes taken daily for several

Finding days from the horizon of the sea, or by the method of re-
the Longi- flection from an artificial horizon.

tude. If by these observations the daily rate is found to be nearly the same,—that is, if the chronometer gains or loses nearly the same portion of absolute time daily,—it may be depended on for finding the longitude; but if its rate is unequal, it must be rejected, as the longitude inferred from it cannot be expected to be accurate.

It would be proper to have two chronometers, and that they should be wound up at different stated times of the day, so that if one should be found stopt, either through neglect in winding up or otherwise, it may be set by the other, observing to apply the former interval of time between them, and the change in their rates of going in that interval.

PROB.—To find the longitude of a ship at sea by a chronometer.

Let several altitudes of the sun or a fixed star or planet be observed, and find the true mean altitude; with which, and the ship's latitude, and declination of observed body, compute the mean time of observation as in sect. ii.

To the mean of the times of observation, as shown by the chronometer, apply the error and accumulated rate. Hence the mean time under the meridian of the place where the error and rate were established will be known; to which apply the difference of longitude in time between that place and Greenwich, and the mean time of observation under the meridian of Greenwich will be obtained. The difference between the time at the place of observation and that at Greenwich will be the longitude of the ship in time; and it is east or west according as the time is later or earlier than the Greenwich time.

Ex. 1.—May 30, 1857, at 3^h P.M. (mean time nearly), in Lat. 30° 20' S., and Long. by account 155° 10' E., when a chronometer showed 4^h 40^m 50^s, the observed altitude of the sun's L.L. was 22° 10', the index correction was -7' 10", and the height of the eye above the sea was 20 feet; required the longitude.

On May 20 the chronometer was fast on Greenwich mean time 4^m 50^s, and its daily rate was 2^s·5 losing.

SECT. IV.—TO FIND THE LONGITUDE BY MEANS OF A LUNAR DISTANCE.

PROB. 1.—Given the apparent distance between the moon and sun, or a fixed star or planet, and the apparent and true altitudes of these bodies, to find the true distance, or, as it is called, to clear the distance.

Rule 1. (Borda's method).—Add together the logarithmic cosines of the true altitudes, the logarithmic secants of the apparent altitudes, the logarithmic cosines of one-half the sum of the apparent altitudes and apparent distance, and of this last arc, less the apparent distance. From one-half of this sum subtract the logarithmic cosine of one-half of the true altitudes; the result, rejecting 10 in the index, is the logarithmic sine of an arc. Find the logarithmic cosine of this arc, and add to it the logarithmic cosines of one-half of the true altitudes; the result, rejecting 10 in the index, is the logarithmic sine of one-half of the true distance required. Or,—

Rule 2.—Find the auxiliary angle A (which is given in the nautical tables of Inman, Norie, Riddle, and others).

Take the versed sine of the difference of the true altitudes. To it add the versed sines of the sum and difference of the auxiliary angle A and the apparent distance; under the difference of the apparent altitudes place the auxiliary angle A, and take their sum and difference; add together the versed sines of these two arcs, and subtract from the former quantity; the result is the versed sine of the true distance.

Ex.—Required the true distance of the moon from the sun, having given—

PROB. 2.—To find the longitude by a lunar observation. Get a Greenwich date, and to this date take out the moon's horizontal parallax and semidiameter. Increase the semidiameter for the augmentation corresponding to the moon's altitude.

Find the apparent and true altitudes of the centre of the moon and of the sun or star which is observed, and the apparent central distance. From these elements compute the true distance as in the last problem, and find the mean time at Greenwich corresponding to it, as shown in chap. ii, sect. iv, p. 38.

If the sun or star be not too near the meridian at the time of observation, compute the mean time at the ship from its altitude; if it be too near, compute the mean time from the moon's altitude. The difference between the mean times of observation at the ship and Greenwich will be the longitude of the ship in time, which is E. or W. according as the time at the ship is later or earlier than the Greenwich mean time.

Ex. 1.—January 3, 1857, at 2^h 30^m P.M., in Lat. 49° 20' N., and Long. 15° 40' E., the following lunar was taken:—

Obs. alt. Sun's L. L. 24° 40' 10"	Obs. alt. Moon's L. L. 21° 36' 40"	Obs. dist. N. L. 90° 28' 10"

CHAP. V.—OF THE VARIATION OF THE COMPASS.

The variation of the compass is the deviation of the points of the mariner's compass from the corresponding points of the horizon, and is denominated *east* or *west* variation, according as the north point of the compass is to the east or west of the true north point of the horizon.

(A particular account of the variation, and of the several instruments used for determining it from observation, may be seen under the article *MAGNETISM*, where the method of communicating magnetism to compass-needles is also fully described.)

Besides the variation, there is also the deviation of the compass arising from the local attraction of the iron on board ship, of which we have already given an account in the former part of this article. This deviation is always taken into account in ships of the Royal Navy, but not

Variation
of the
Compass.

always in ships belonging to the mercantile navy. In the latter case the variation is the whole difference between the observed bearing of the sun and the compass bearing; in the former, allowance must be made for deviation. We shall take deviation into account, as it is easy to omit it when it is not required.

To correct the variation for deviation, it will be sufficient to place under the variation, when determined by observation with its proper name, the deviation with a name *opposite* to its true name. Add these when the names are alike, and subtract the less from the greater if the names are different; and the remainder, with the name of the greater, is the true variation.

PROB. 1.—Given the latitude of a place, and the sun's declination, and the sun's magnetic amplitude, to find the deviation. [*Obs.*—The amplitude is the distance from the east point at which it rises, or from the west point at which it sets.]

Rule.—To the log. secant of latitude add log. sine of sun's declination; the sum, rejecting 10 from the index, will be the log. sine amplitude, which is east if the body is rising, and west if it be setting. The variation is the difference between the true and magnetic amplitudes if these be of the same name, and their sum if of different names. Also the variation is east if the true bearing is to the right of the compass bearing, west if the true bearing is to the left of the compass.

Ex.—May 18, 1857, about 5^h 25^m A.M., in Lat. 51° 5' N., Long. 143° W., the sun rose by compass E. 6° 40' S., the ship's head being E.; required the variation.

Ship, May 17..... 17^h 25^m 0^s
Longitude..... 9 32 0 W.

Latitude..... 51 5 0 N. Sin..... 9.526303

Sec..... 0.201909

Sin amplitude. 9.728212

True bearing..... E. 32° 20' 0" N.

Compass..... E. 6 40 0 S.

39 0 0 W.

Deviation..... 8 50 0 W.

Variation..... 47 50 0 W.

It may be remarked, that the sun's amplitude ought to be observed at the instant the altitude of its lower limb is equal to the sum of fifteen minutes and the dip of the horizon. Thus, if an observer be elevated 18 feet above the level of the sea, the amplitude should be taken at the instant the altitude of the sun's lower limb is 19° 11'.

PROB. 2.—Given the magnetic azimuth, the altitude and declination of the sun, together with the latitude of the place of observation, to find the variation of the compass.

Rule.—Find the polar distance by adding 90° to the declination if the altitude and declination have unlike names, and subtracting the declination from 90° if they have the same name.

Take the difference of the latitude and altitude, and obtain the sum and difference of this quantity and the polar distance.

To the log. secants of the altitude and declination add the halves of the log. haversines of the last two arcs; the result, rejecting 10 in the index, is the haversine of the true bearing, which take from the table. Or if a table not contain-

ing haversines is used, to the log. secants as before add the log. sines of half the arcs obtained as before; one-half of the result is the log. sine of half the true bearing. Double the arc taken out of the table is the true bearing.

Mark the true bearing N. or S., according as the latitude is N. or S., and E. or W., according as the observed body is E. or W. of the meridian. The variation then can be found as before.

Ex.—On May 5, 1857, about 8^h 10^m 0^s A.M., mean time, in Lat. 51° 10' N., Long. 140° W., the sun bore by compass S. 65° 25' E., and the observed altitude of the sun's lower limb at the same time was 28° 30' 10", the index correction was +1' 20", and the height of the eye above the sea 15 feet, the ship's head being N.W.; required the variation of the compass.

CHAP. VI.—OF THE TIDES.

The theory of the tides has already been explained under the article ASTRONOMY, and will again be further illustrated under that of TIDES. In this place, therefore, it remains only to explain the method of calculating the time of high water at a given place.

As the tides depend upon the joint actions of the sun and moon, and therefore upon the distance of these objects from the earth and from each other; and as, in the method generally employed to find the time of high-water, whether by the mean time of new moon, or by the epacts, or tables deduced therefrom, the moon is supposed to be the sole agent, and to have a uniform motion in the periphery of a circle whose centre is that of the earth; it is hence obvious that this method cannot be accurate, and by observation the error is sometimes found to exceed two hours. This method is therefore rejected, and another given, in which the error will seldom exceed a few minutes, unless the tides are greatly influenced by the winds.

The Tides

The Tides.

The Tides.

TO FIND THE TIME OF HIGH-WATER.

Rule.—Let the approximate time of high-water be found, by taking the corrections for the moon's horizontal parallax for the nearest noon or midnight from Table I. Again, to this time and the given longitude take from the *Nautical Almanac* the moon's horizontal parallax. Also to the time of the moon's transit over the meridian of Greenwich apply the variation answering to the longitude and daily variation between the given and preceding day if the longitude is E. Subtract this from the transit over the meridian of Greenwich, and the remainder will be the time of transit over the meridian of the given place. But if the longitude be W., the correction answering to the longitude and daily variation of transit between the given and following day must be added to the time of transit over the meridian of Greenwich, to obtain the time of transit over the meridian of the given place. To the time of high-water, if new and full moon at the given place, add the reduced time of transit over the meridian of the same place, and to the sum apply the equation from the table answering to the time of transit and horizontal parallax formerly found; the result will be the true mean time of high-water required. The apparent time may be found by applying the equation of time, with its proper sign.

Ex. 1.—Required the time of high-water at Leith on Wednesday the 10th of May 1837, in Long. $3^{\circ} 11' W$.

By the rule, the time of high-water will be about six o'clock in the evening. In this case, the moon's horizontal parallax will be $54' 16''$, and the time of transit $4^h 50^m$ mean time, or $4^h 54^m$ apparent time by applying the equation of time $3^m 50^s$ by addition.

Apparent time of transit of upper meridian...	$4^h 54^m$
Equation from the table to horizontal parallax $54' 16''$, and transit $4^h 54^m$, subtract.....	$-1\ 18$
Remainder	$3\ 36$
Time of high-water at new and full moon	$+2\ 20$
Apparent time of high-water.....	$5\ 56$
Equation of time.....	$-0\ 4$
Mean time of high-water.....	$5\ 52$

If the sum exceed $12^h 25^m$, subtract this number from it; if it exceed $24^h 50^m$, subtract as before, and the remainder will be the time of high-water in the afternoon of the given day nearly. The time of high-water of the tide preceding may be found nearly by subtracting 25^m from it, and the succeeding tide by adding 25^m to it. In cases of great accuracy, however, a computation should be made for each tide in a manner similar to that above.

Ex. 2.—Required the time of high-water at Aberdeen on the 21st of June 1837, in Long. $2^{\circ} 6' W$.

As before, the time of high-water will readily be found to be about three o'clock.

Here the horizontal parallax of the moon will be $60' 30''$, and the mean time of transit on the given day $15^h 32^m$. But as this transit exceeds 12^h , it will be necessary to take the time of transit over the under meridian, or, what comes to the same thing, half the

sum of the transits on the given and preceding days, or, $\frac{1}{2}(14^h 32^m + 15^h 32^m)$	$=15^h\ 2^m$
Correction from the table.....	$-0\ 44$
Remainder.....	$14\ 18$
High-water at new and full moon	$+1\ 10$
Sum exceeding 12^h	$15\ 28$
By rule, subtract	$12\ 25$
Apparent time of high water	$3\ 3$
Equation of time.....	$+0\ 1$
Mean time.....	$3\ 4$

The Tides.

Ex. 3.—Required the depth at Aberdeen at the same time, the rise of spring tides being 19 feet, denoted by a in Table II., part 1, and that of the neap 14 feet, by b .

Now, by Table II., part 1, to transit $15^h 2^m$, and horizontal parallax $60' 30''$, will be obtained $0.917 \times 19 + 0.242 \times 14 = 20.8$ feet.

Ex. 4.—Required the height of the tide at $3^h 15^m$ after high-water.

By part 2, 20.8×0.5 = 10.4 feet.

In this manner, the time and rise of the tide may be readily obtained nearly, unless both are much influenced by the strength and direction of the wind.

In the preceding pages we have not considered it our province to supply the reader with the tables which have been made use of in the solution of the several problems—*e.g.*, traverse tables, tables of meridional parts, corrections for dip, parallax, refraction, and log. haversines, log. rising, middle time, half-elapsed time, &c. For these, and for further information, we refer him to the works on Navigation already mentioned. Some of the rules we have given will be found to differ in some respects from those given in these works. These discrepancies, however, arise entirely from the slightly different form in which the formulæ on which the rules are based are made to appear, but not at all on any difference of principle. We have generally retained the forms of the formulæ which are best known to astronomical students. For example, we have retained Borda's method of clearing the distance, in lieu of the slight deviations from it which are frequently employed, not merely as being equally correct with the latter, but as possessing some historical interest. In clearing the distance by natural versed sines, it is not difficult to put the formulæ in such a form that the *sum* only of the versed sines may be taken. We have retained the formula in which two of the versed sines appear with a negative sign, as being that with which the readers of Hymer's Astronomy are already acquainted. Whenever the reader is familiar with astronomical formulæ, we recommend him to study the rules given in these pages with the appropriate formulæ before him; these he will find in any work on astronomy treated mathematically. In all cases, however, it is believed that, by a careful study of the rules and directions contained in this article, the reader will find himself possessed of all the information which will enable him to navigate a ship.

(J. W—Y.)

NAVIGATION, INLAND.

Introduction. THE mariner's compass, it is believed, was first used at the commencement of the fourteenth century. Its introduction gave a new character to commercial enterprise, as it afforded the means of promoting to an almost unlimited degree the progress of maritime discovery. Since that early period the pursuit of Navigation has not only been the grand object to which the labours of Columbus and of all subsequent explorers of the world have been directed; but the researches of the philosopher, the astronomer, the geographer, the mechanician, and the engineer, have all been instrumental in bringing to maturity and perfection the various branches which constitute the system of Navigation as it now exists.

Origin of navigation. That system, though made up of many subsidiary parts, may conveniently and naturally be divided into two great departments. One of these is treated of in a separate article under the head of NAVIGATION; the other, which forms the subject of the present treatise, is termed Inland Navigation.

Its division into two departments. It may shortly be defined as that branch of navigation which extends from the sea to the land, and affords the means of transport throughout the interior of a country. To form a correct estimate of the importance of this subject, it must be viewed in connection with the entire system of which it forms a part. For, how can we fully enjoy the benefits of those mighty results of science and of art, by which sailing vessels of all classes are now enabled to transport their cargoes from shore to shore, with comparative ease and safety, and gigantic steamers to traverse the ocean with certainty and despatch, if we do not, in addition to exhibiting the beacon light to welcome the approach of ships to our coasts, afford the means of withdrawing them from the ocean billows into sheltered havens, where their lading may be discharged, and cargoes of our country's produce may be shipped for foreign lands. It should be borne in mind, that it is only when the mariner approaches his destined port that the dangers caused by rocks, shoals, sand-banks, tides, and currents, beset his course; and the means of securing shelter for his vessel, and of opening up a passage into the interior of the country, may be held as embraced under the extensive subject of Inland Navigation.

What inland navigation is. The article HARBOURS fully discusses the construction of piers and breakwaters; and our present treatise will therefore be confined to Canal and River Navigation.

Harbours. Under these general heads we propose to give a brief account of canals, as applied to the purpose of transport by means of boats, and also on the larger scale, as affording to sea-borne vessels a sheltered and direct route to their destined ports. Our notice of rivers will embrace the navigation of their upper or landward streams, and also the varied means employed in opening up and rendering navigable their seaward or tidal compartments, which will necessarily lead us to consider the conservation of estuaries and the formation of bars. Viewed even in this restricted light, it will be found that inland navigation forms an extensive and intricate department of hydraulic engineering.

Topics to be discussed in present article. It is proper in the outset to state, that it is not our intention to explain the nature or principles of the varied class of works which the engineer finds it necessary to adopt in carrying out such operations as those to which we have alluded. At the present time, when so much is written on all branches of engineering, such a course would be uncalled for, and would indeed extend the present treatise greatly beyond the limits to which it must necessarily be restricted. For information as to such details, we must therefore direct the reader to the different books to which

we shall have to refer, as containing full information on the subjects of which they treat. Our aim is rather to present the reader with a general *résumé* of the state of our knowledge respecting the practice of engineering, as applicable to inland navigation in all its branches, and to confine such detailed remarks as we may have to offer, to those parts of the subjects only, which are not fully treated in works already published; and here we must express our regret, that although we have many treatises expounding the principles of engineering, nevertheless the engineers of the present day have given comparatively few accounts of the effects that have followed the application of these principles in particular cases. In drawing up the following pages, the writer has found great difficulty in obtaining authentic information on *applied* engineering; and this must be his excuse for having in some of the sections been obliged to apply, it may be thought too largely, to his own experience for illustrations of his subject.

Canals.

SECT. I.—CANALS.

It must be obvious to all, that railways, from which we Canals. have of late years derived such inestimable advantages, have now in a very great measure superseded, and certainly for the future must prevent, the general extension of canals. The great objections to relying on canals as the medium of regular and uninterrupted internal communication in this country, are the difficulty of obtaining a sufficient supply of water to prevent stoppages during dry seasons, the interruption to which they are exposed from ice during winter, and above all, in these days of express railway trains and electric telegraphs, the very limited speed at which the boats which navigate them can be propelled. Sir John Rennie, in speaking of the successful attempts made to introduce swift boats on canals, and the great improvement that was thereby effected in canal transport, says,—“All this, however, came too late; for although it would have been readily acknowledged at an earlier period, and might perhaps for a while have retarded the railway system, yet when once the latter was established, its superiority became manifest, and its progress irresistible.”¹ These truly are considerations which make canals, when compared to railways as a means of transport and communication, appear so very disadvantageous, that it may at first sight be considered as uncalled-for to describe, even briefly, a class of works which, in the present day, may be regarded by some readers as almost entirely superseded. But although this remark may perhaps be justly considered applicable to those canals which effect a purely inland communication from town to town, it does not, in any degree, apply to that larger class of works called ship canals, which afford to sea-borne vessels an inland course, and enable them to avoid the dangers of a lengthened coasting voyage—an object of the highest importance to navigation, and one which it is obvious cannot be superseded by a railway. But, independently of this reservation on behalf of these peculiar works, it appears to us that the simple consideration of the great antiquity of navigable canals, their wide-spread introduction throughout the world, the important place which they have so long occupied in the commercial history of every country, and above all, the noble specimens which they afford of hydraulic engineering, should lead us naturally and imperatively to give some notice of their origin and subsequent progress; and this we shall do as briefly as possible, not so much from any feeling that the subject is superseded, or is unimportant, but because it will

¹ Transactions of Inst. of Civil Engineers, vol. v., p. 78.

Canals. be found fully and ably treated in the works to which we shall have occasion to refer.

From the writings of Herodotus, Aristotle, Pliny, and other ancient historians, we learn that canals existed in Egypt before the Christian era; and there is reason to believe that, at the same early period, artificial inland navigation also existed in China. Almost nothing, however, save their existence, has been recorded with reference to these very early works; but soon after the commencement of the Christian era, canals were introduced, and gradually extended throughout Europe, particularly in Greece, Italy, Spain, Russia, Sweden, Holland, and France.¹

In speaking, however, of the earliest of these works, it is not to be supposed that they resembled the modern canals as now constructed in our own and other countries. Early as inland navigation was introduced, it was not until the invention of canal-locks, by which boats could be transferred from one level to another, that the system was rendered generally applicable and useful; and it has been truly remarked, "that to us, living in an age of steam-engines and daguerreotypes, it might appear strange that an invention so simple in itself as the canal-lock, and founded on properties of fluids little recon-dite, should have escaped the acuteness of Egypt, Greece, and Rome."² Not only, however, had the invention escaped the notice of the ancients, but what is more striking, the several gradations made towards the attainment of that simple but valuable improvement appear to have been so gradual that, like many discoveries of importance, great doubts exist as to the *person* and even the *nation*, by whom canal-locks were first introduced. One class of writers attributes the discovery to the Dutch; and Messrs Telford and Nimmo, who are understood to have written the article on Inland Navigation in *Brewster's Edinburgh Encyclopædia*, adopt the conclusion that locks were used in Holland nearly a century before their application in Italy; while, on the other hand, the invention has been strongly and not unreasonably claimed for engineers of the Italian school, and, in particular, for Leonardo da Vinci, the celebrated engineer and painter. Without, however, entering into a discussion of this question, which it is now probably impossible to solve, we may safely state, that during the fourteenth century the introduction of locks, whether of Dutch or Italian origin, gave a new character to inland navigation, and laid the basis of its rapid and successful extension. And here it may be proper to remark, that the early canals of China and Egypt, although destitute of locks, do not appear to have been on that account formed on a uniformly level line unadapted to varying heights. It is very doubtful, indeed, if the use of locks has even yet been introduced into China, intersected as it is by many canals of great antiquity and extent;³ and in order to pass boats from one level to another, the Chinese have, from a very early period, employed stop-gates and inclined planes of rude construction. Nevertheless, the invention of locks was, as already noticed, a most important step in the history of canals; and that mode of surmounting elevations may be said to be almost universally adopted throughout Europe and America. Inclined planes and perpendicular lifts have, it is true, been employed in these countries, as will be noticed hereafter; but the instances of their application are undoubtedly rare.

Languedoc Canal. But in proceeding to illustrate the progress of canals, we may, without tracing their gradual introduction from country to country, remark at once, that we find the French, at the end of the seventeenth century, in the reign of Louis XIV., forming the Languedoc Canal, designed by Riquet, between

the Bay of Biscay and the Mediterranean, a gigantic work which was finished in 1681. It is 148 miles in length, and the summit level is 600 feet above the sea; while the works on its line embrace upwards of one hundred locks and about fifty aqueducts,—the whole forming an undertaking which is a lasting monument to the skill and enterprise of its projectors; and with this work as a model, it seems strange that Britain should not, till nearly a century after its execution, have been engaged in vigorously following so laudable an example. This seems the more extraordinary, as the Romans in early times had executed works in England, which, whatever might have been their original use, whether for the purposes of navigation or drainage, were ultimately, and that even at an early period, converted into navigable canals. Of these works, we particularly specify the Caer Dyke and Foss Dyke cuts in Lincolnshire, which are by general consent admitted to have been of Roman origin. The former extends from Peterborough to the River Witham, near the city of Lincoln, a distance of about 40 miles; and the latter extends from Lincoln to the River Trent, near Torksey, a distance of 11 miles. The Caer Dyke exists now only in name; but the Foss Dyke is at this moment an efficient and flourishing navigation; and having been lately professionally engaged in its improvement, the writer had occasion to inquire somewhat minutely into its history. Regarding this *oldest* British canal, Camden, in his *Britannia*, states that the Foss Dyke was a cut originally made by the Romans, and that it was deepened in the year 1121 by Henry I.; but to what extent it was deepened does not appear. In 1762 it was reported on by Smeaton and Grundy, who found the navigable depth at that time to be 2 feet 8 inches, and recommended several works for its improvement, which appear, however, not to have been executed. In 1782 Smeaton was again employed, and deepened the navigation to 3 feet 6 inches; but it does not appear that its width was increased;⁴ and from that period it remained in a very imperfect state till 1840, when Messrs Stevenson of Edinburgh were employed to design works for assimilating the Foss Dyke, both as regarded the breadth and depth of the navigable channel, to the Rivers Witham and Trent, with which it communicated. Upon examination, the depth of the Foss was found to be 3 feet 10 inches, and its breadth in many places was insufficient for the passage of boats, for the convenience of which occasional passing places had been provided; and it was resolved to increase its dimensions, and otherwise repair the whole work. Accordingly, the canal was widened to the *minimum* breadth of 45 feet, and deepened to the extent of 6 feet throughout; alterations which were accomplished without stopping the traffic. The entrance-lock was renewed, and a pumping-engine was erected for supplying water from the River Trent during dry seasons; and that ancient canal, which is quoted by Telford and Nimmo "as the oldest artificial canal in Britain," is now in a state of perfect efficiency, forming an important connecting link between the Trent and Witham navigations.

Notwithstanding the existence of this early work, however, and of some others in the country, particularly the Sankey Brook navigation, opened in 1760, it is generally admitted that the formation of the Bridgewater Canal in Lancashire, the act for which was obtained in 1759, was the commencement of British canal navigation; and that Francis, Duke of Bridgewater, and Brindley the engineer, who were its projectors, were the first to give a practical impulse to a class of works which, under the guidance mainly of Smeaton, Watt, Jessop, Nimmo, Rennie, and Tel-

Canals.

Ancient Roman canals in England.

Foss Dyke Canal.

Bridge-water Canal.

Canals. ford, has been very generally adopted throughout the country, and has undoubtedly been of vast importance in promoting its commercial prosperity.¹ It is believed that the canals which have been constructed in Britain exceed in the aggregate 4713 miles, and the system has been extensively carried out both in Europe and America.

Ship canals. The introduction of canals adapted for the passage of boats was soon followed by a larger class of works, suited for the accommodation of sea-borne vessels. Thus the Forth and Clyde Canal, projected by Smeaton in 1766, and the Crinan Canal, executed by Rennie, are examples of navigations to enable sea-borne vessels of small size to pass from opposite coasts of the country, and escape long, and it may be hazardous, sea voyages. But these works are completely surpassed by others which have been formed on a scale of much greater magnitude, to admit vessels of heavy burden and large draught of water. Of these we may mention the Great North Holland Canal, designed and constructed by M. Blanken.² That canal, which extends from Amsterdam to the Helder, a distance of 51 miles, was finished in 1825. It is about 125 feet in breadth at the water surface, 31 feet at the bottom, and no less than 20 feet in depth of water; and what is most worthy of notice, and is indeed a characteristic of all Dutch engineering works, the greater part of it is protected from the German Ocean by embankments faced with wicker-work, the surface of the water in the canal being below the level of the sea at high water. At the time the writer inspected this work the sea was several feet higher than the surface of the water in the canal, and the vessels were actually being locked down from the ocean into the fertile plains of Holland. The object of this canal is to enable vessels trading from Amsterdam to avoid the islands and sandbanks of the dangerous Zuider Zee, the passage through which in former times often occupied as many weeks as the transit through the canal now occupies hours.³

Caledonian Canal. But our own country furnishes us with a similar work of great magnitude and boldness; we allude to the Caledonian Canal, originally projected by Watt and Jessop, and ultimately executed by Telford, which forms an inland navigation, composed partly of natural lakes, and partly of artificial canal, extending from Inverness to Fort-William, a distance of 60 miles. The artificial part of it is 120 feet in width at the top-water level, 50 feet at the bottom, and affords 20 feet of maximum depth. By means of this inland communication vessels are enabled to avoid the dangers of the Pentland Firth, and also in some measure the intricate navigation of the Western Islands; and while the Dutch in their great canal had to encounter the difficulties occasioned by the proverbial *lowness* of their country, Telford, in constructing the Caledonian Canal, had to deal with the ruggedness of a succession of Highland glens, and to surmount the summit-level of Loch Oich, which is about 80 feet above the level of the sea. Accordingly, in addition to many heavy works which occur in its course, there is at one point on the Caledonian Canal a succession of eight locks, by means of which a vessel of nearly the largest class of merchantmen can be raised or lowered through a height of 60 perpendicular feet. The locks, which are in close succession, rise one above another like a series of gigantic steps; and this unique and extensive marine ladder has not inappropriately been termed "Neptune's Staircase."⁴

Canals. It must be obvious that, in successfully carrying out works of such a nature, and on so gigantic a scale, no ordinary amount of engineering skill is requisite. Vast reservoirs must in some cases be formed for storing the water necessary to supply during dry seasons the loss by lockage, leakage, and evaporation. Feeders must be made to lead this water to the canal; hills must be pierced by tunnels; valleys must be crossed on lofty embankments, or spanned by spacious aqueducts; and above all, the whole must be conceived and laid out with scrupulous regard to the all-important object of securing the works against injury from an overflow of water during floods, and a consequent inundation of the surrounding country. Moreover, the necessity of laying out the canal in level stretches, and surmounting elevations by means of locks or inclined planes, occurring at intervals, often occasions much difficulty, and greatly restricts the resources of the engineer. Taking, then, all these circumstances into consideration, and bearing in mind that canals were the pioneers of railways, we think it may safely be affirmed that the canal engineers of former days had much more serious *physical* difficulties to contend with than are experienced in carrying out the railways in modern times; if we except such works as the Britannia Bridge, the high-level bridge of Newcastle, the Boxhill Tunnel, and some other kindred works. But, indeed, their *mechanical* difficulties were also greater; for the introduction of steam, and its wide-spread application to all engineering operations, affords facilities to the engineers of modern times which Smeaton at the Eddystone, Stevenson at the Bell Rock, and Rennie and Telford in their early navigation works, did not enjoy. We therefore gladly embrace this opportunity of acknowledging the distinguished merits of the engineers who practised at the end of the former and the commencement of the present century.

We have already said that we cannot in this treatise enter into details as to the construction of the various works adopted in executing canal navigations; and we shall here close our short historical notice of these works by submitting the following digest of the general principles which should guide the engineer in selecting the route and designing the construction of a line of canal:—

1. The first object to which attention ought to be directed is the supply of water, on which the efficiency of a canal mainly depends. If there be no natural lake in the district available for storage, the engineer must select such situations as are suitable for the construction of artificial reservoirs. The conditions to be attended to in selecting the positions for these works are, that they command a sufficient area of drainage to supply the necessary amount of water; that their outlets are at such an elevation as to admit of water being conveyed to the summit-level of the canal; and that the embankments for retaining the water be erected on sites affording a favourable foundation, and so situated with reference to the valley above them that they shall, with the minimum height and breadth of embankment, dam up the maximum amount of water. It is further necessary to consider whether the subsoil of the valley forming the reservoirs is throughout of so retentive a nature as to prevent leakage; and it is also essential to provide, by means of waste weirs, for the discharge of floods. The Caledonian Canal is, in this respect, very favourably situated; no artificial reservoir having been required. Nearly the whole supply is

¹ *History of Inland Navigation, particularly those of the Duke of Bridgewater*, London, 1786. Hughes' "Memoir of Brindley," Weale's *Quarterly Papers*, London, 1843.

² It was here that Bakker, a burgomaster of Amsterdam in 1688, introduced his "camel" for floating large vessels over the shoals of the Pampus, by means of which, according to Sir John Leslie, an Indianman which drew 15 feet water had its draught reduced to 11 feet.

³ The connection of the Atlantic and Pacific oceans by means of a navigable canal has long been under consideration, and the question has of late years assumed a more practical aspect. (For a review of the various schemes which have been proposed for carrying out this desirable object, the reader is referred to communications by Mr Joseph Glynn and Lieut.-Col. Lloyd, in the *Trans. of the Society of Civil Engineers*, vol. ix., p. 58, and vol. vi., p. 399.)

Canals.

derived from Lochs Ness, Oich, and Lochy, which, indeed, constitute the greater part of the navigation; they afford ample depth of water, and though on different levels, they extend in an almost continuous line through the country. In other cases, such as the Union, Forth and Clyde, Crinan, Birmingham, and other canals, it has been found necessary to construct large artificial reservoirs, from which the water is led in feeders to points convenient for forming a junction with the canal. The water in these reservoirs, whether artificial or natural, is stored up in winter, and let off as required during the droughts of summer. In situations where the canal communicates with the sea or a tidal river, and where the natural supply is small, as in the case of the Foss Dyke, the water may be raised by pumping-engines.

Reaches and locks.

2. In determining the direction of a canal, it is of importance to consider the levels of the country through which it passes, and to lay out the work in a succession of level reaches, so as to overcome elevations *in cumulo* at those places where it can be most advantageously effected. This arrangement not only leads to a saving of attendance and expense in working the canal, but is also more convenient as presenting fewer stoppages to the traffic. The means of overcoming the difference of level between the various level-reaches must depend very much on circumstances. With few exceptions, the change of level is effected by means of locks, which generally have a lift of from 8 to 10 feet, though in some cases it is somewhat greater. The dimensions of the locks ought to be regulated by the traffic; but they should, in order to save water, be as near as possible the size of the craft to be passed through them. The smallest class of canals have locks about 8 feet in breadth, and from 70 to 80 feet long; those on the Forth and Clyde are 20 feet in breadth, and 74 feet long; on the Caledonian Canal they are 40 feet broad, and 180 feet long, and on the great Holland ship-canal they are 51 feet broad, and 297 feet long. The water is gradually admitted into and flows from each lock by sluices formed in the gates. Sir William Cubitt, in carrying out the improvements of the Severn navigation, introduced the water through a culvert parallel to the side wall of the lock, and opening in the centre by means of a tunnel, which admits 16,000 cubic feet of water to flow into or out of the lock in $1\frac{1}{2}$ minute; and in little more than that time loaded vessels can be passed through.¹ Inclined planes and perpendicular lifts, which have the great advantage of saving water, have also been adopted in a few cases. In 1837 the writer inspected the Morris Canal in the United States, constructed by Mr Douglas of New York, on the line of which there are no fewer than 23 inclined planes, having gradients of about 1 in 10, and an average lift of 58 feet each. The boats weighed, when loaded, 50 tons, and after being grounded on a carriage, were raised by water-power up the inclines with great ease and expedition. The length of the Morris Canal, which connects the Rivers Hudson and Delaware, and is a most interesting work, is 101 miles, and the whole rise and fall is 1557 feet, of which 223 are overcome by locks, and the remaining 1334 by inclined planes.² But inclined planes were used on the Ketling Canal in Shropshire in 1789, and afterwards on the Duke of Bridgewater's Canal. Mr Green introduced on the Great Western Canal a perpendicular lift of 46 feet; and more recently Mr Leslie, of Edinburgh, and Mr Bateman, constructed an inclined plane on the Monkland Canal, wrought by two high-pressure steam-engines of 25 horsepower each. The height from surface to surface is 96 feet, and the gradient is 1 in 10. The boats are not wholly grounded on the carriage, but are transported in a caisson

of boiler-plate, containing 2 feet of water. The maximum weight raised is from 70 to 80 tons, and the whole transit is accomplished in about 10 minutes. For the five years previous to the end of 1856, the average number of boats that passed over the incline each year was 7500. Sir William Cubitt has also introduced three inclined planes, having gradients of 1 in 8, on the Chard Canal, Somersetshire. One of these inclines overcomes a rise of 86 feet, and they are said to act very satisfactorily.³

Canals.

3. An essential adjunct to a canal is a sufficient number of waste weirs to admit of the discharge of the surplus water which accumulates during floods, and which may, if not provided with an exit, rise to such a height as to overflow the tow-path, and cause a breach in the banks, producing stoppage of the traffic and damage to the adjoining lands. In determining the number and positions of these waste weirs, the engineer must be guided entirely by the nature of the country through which the canal passes. Whenever an opportunity occurs of discharging surplus water into a stream crossed by the canal, a waste weir may safely be introduced; but, independently of this natural facility, the engineer must consider from what quarters, and at what points, the greatest influx of water may be apprehended, and must at such places not only form waste weirs of sufficient size to void the surplus, but prepare artificial courses for their discharge into the nearest streams. These waste weirs are overflows placed at the top water-level of the canal, so that in the event of a flood occurring, the water flows over them, and thus relieves the banks. The want of sufficient escape for flood-water has occasioned overflows of canal banks which were attended with very serious injury to the works, and lengthened suspension of the traffic; and attention to this particular part of canal construction is of essential importance.

Waste weirs.

4. Another very necessary precaution is the introduction of stop-gates at short intervals of a few miles, for the purpose of dividing the canal into isolated reaches, so that in the event of a breach occurring, the stop-gates may be shut, and the discharge of water confined to the small reach intercepted between them, instead of extending throughout the whole line of canal. In large works these stop-gates may be most advantageously formed in the same manner as the upper gates of locks, two pairs of gates being made to shut in opposite directions. In small works they may be made of thick planks, which are slipped into grooves formed at those narrow parts of the canal which occur under road bridges, or at contractions made with grooves at intermediate points to receive them. Self-acting stop-gates have been tried, but their success has not been such as to lead to their general introduction. Stop-gates are further found to be very useful in cases of repairs, as they admit of the water being run off from a short reach, when the repairs can be made, and the water restored, with comparatively little interruption to the traffic. Their value in obviating serious accidents was well exemplified on one occasion in the experience of the writer, when the water during a heavy flood flowed over the towing-path at the end of an aqueduct adjoining a high embankment, and the uncontrolled current carried away the embankment, and the soil on which it rested, to the depth of 80 feet, as measured from the top water-level. The stop-gates were, on the occasion referred to, promptly applied, and the discharge confined to a short reach of a few miles, otherwise the injury (which was, even in its modified form, very considerable) would have been enormous.

Stop-gates.

5. For the purpose of draining off the water to admit of repairs after the stop-gates have been closed, it is necessary to introduce, at convenient situations, a series of

Offets.

³ Stevenson's Sketch of Civil Engineering in North America.

Rivers. exits called offlets, consisting of pipes placed at the level of the bottom of the canal, and fitted with sluices which can be opened and shut when required. These offlets are generally formed at aqueducts or bridges crossing rivers where the contents of the canal can be run off directly into the bed of the stream, the stop-gates on either side being closed so as to isolate the part of the canal from which the water is withdrawn.

Drainage of tow-paths. (6.) In executing the work, provision must be made for the proper drainage of the tow-paths, especially in cuttings. The drainage of the tow-paths should be carried to a sky drain at the bottom of the cutting, and at intervals passed below the tow-path into the canal. The preservation of the banks at the water-line is also a matter of importance. "Pitching" with stones and "facing" with brushwood are employed, and, in the writer's experience, the latter, if well executed, forms an economical and effectual protection.

Paddling. (7.) In forming the *alveus* or bed of the canal, care must be taken, particularly on embankments, and also in cuttings, if the soil is porous, to provide against leakage by the application of puddle. And here it is proper to remark, that an all-important matter, as affecting the construction of the works, is the possibility of getting clay in the district, or such other soil as may be worked into puddle, on the good quality of which the stability of the reservoir embankments, and the imperviousness of the beds and banks of the canal, mainly depend.

These are the only points of general application in the construction of canals to which we can advantageously direct attention in the present communication. In carrying them into practice, the engineer must be guided partly by the valuable details to be found in the works to which reference is made in this article, but mainly by that experience which can be gained only by the study of works in actual operation.

We do not propose to extend our remarks to the means of conducting traffic on canals and rivers, and have to refer the reader for information on that subject to observations and works on Traction and Steam Navigation. On the former subject the reader may consult the observations, by Mr Walker and Mr George Rennie, in the *Transactions of the Royal Society* and of the *Institution of Civil Engineers*; and especially the very valuable researches on Hydrodynamics, by Mr Scott Russell, in the *Edinburgh Philosophical Transactions*. On the latter he is referred to the articles STEAM-ENGINE, and STEAM NAVIGATION.¹

SECT. II.—RIVERS, THEIR PHYSICAL CHARACTERISTICS.

Difference between canal and river navigation. From what has been said, it will be seen that a canal may be described as a work by which water is diverted from its natural course, and made to occupy a channel prepared for its reception, extending through the country for the transport of boats and vessels. Canal navigation is thus entirely *artificial* in its character. In this respect it differs from river navigation, which may be described as the art of using, for the purposes of inland communication, rivers flowing in their natural courses, and of applying means to render them subservient to the purposes of navigation in cases where the depth is limited, or where rapid currents exist. Our consideration of rivers must therefore necessarily comprehend a general sketch of their physical characteristics, and the laws of their motion, as a necessary introduction to the more practical part of the subject, embracing the engineering works required for their improvement, with which we have chiefly to deal in this treatise.

Rivers. As introductory, therefore, to the remarks which are to follow, it seems desirable to premise, as described by the writer in a communication to the Royal Society of Edinburgh,² that in all rivers affected by tidal influence, two physical boundaries, more or less apparent, are invariably found to exist, caused by the influx of the tidal wave through firths or bays, and the modification it receives in its passage up the gradually rising inclination or slope of a river's bed. These boundaries again produce three compartments. The seaward, or lowest of these, the writer termed the "sea proper;" the next, or intermediate one, into which the sea ascends, and from which it again withdraws itself, was termed the "tidal compartment of the river;" and the highest, or that which is above the influence of the sea, the "river proper." Their relative extent in different situations is influenced not only by the circumstances under which the great tidal wave of the ocean enters the river, but by the size of its stream, the configuration and the slope of its bed, and, in short, by every natural or artificial obstruction which is presented to the free flow of the tidal currents along its channel.

These three compartments possess very different physical characteristics. The presence of *unimpaired tidal phenomena* in the lowest, the *modified flow of the tide*, produced by the inclination of the river's bed in the intermediate, and the *absence of all tidal influence* in the highest compartment, may be shortly stated as the phenomena by which these spaces are to be recognised. The tides in the "sea proper" compartment of an estuary, for example (although the place of observation be several miles embayed from what in strictness could be called the "sea" or "ocean"), will be found to resemble those of the adjoining sea with which it communicates,—1st, in the identity of the levels of low water; 2d, in the shortness of the time which elapses between the cessation of ebbing and the commencement of flowing, or, in other words, the absence of any protracted period of low water, during which the surface appears to remain stationary at the same level; 3d, in the symmetrical form traced by the passage of the tidal wave; and 4th, in the range of tide, so far as that is not influenced by the formation of the shores in narrow seas or channels. In ascending into the intermediate compartment, however, the level of the low water is no longer the same; the range of tide, excepting in peculiar cases, becomes less, and is gradually decreased as the bed of the river rises, and at length a point is reached where its influence is not perceptible. In this intermediate section the phenomena of *ebbing and flowing* are still found to take place, but the times of ebb and flow do not remain constant, that of ebb gradually gaining the ascendancy; the duration of low water being gradually protracted as we proceed upwards, until the influence of tide is unknown. This forms the boundary line of the upper compartment, the characteristic of which is the total absence of ebbing and flowing; the river at all times pursuing its downward course in an uninterrupted stream, and at an unvarying level, except in so far as may result from the changes due to land floods.

In the investigation of these different characteristics, the variable nature of the elements to be dealt with must be kept in view. The river, for example, is liable to be affected by floods, and the state of the tides by winds and other causes; and therefore a great degree of precision in defining these spaces cannot in all cases be expected, nor indeed is it necessary for the purpose of the present inquiry. But it is satisfactory to know that the termination of the low-water level at the separation of the seaward and intermediate spaces, as laid down by marine surveyors, simply from ob-

Rivers.  servation of the tidal phenomena, has in several situations been found to agree exactly with the position of that boundary as determined by engineers by means of accurate levelling, combined with careful tidal observations.

Tidal phenomena of Dornoch Firth. But an example in actual practice will best illustrate what is meant, and for this purpose we shall refer to the investigation of the tidal phenomena, made by the writer in 1842, of the Firth of Dornoch and Kyles of Sutherland in Cromartyshire. By referring to the small chart of the Dornoch Firth in Plate I., the reader will be better able to follow the illustrations to be given. The harbour of Portmahomac, marked A on the chart, about 3 miles from Tarbetness Lighthouse, was selected as the place at which to observe the *ocean* or *sea wave*. The second station at which it was found convenient to institute observations was within the Firth at Meikleferry, marked B, about 3 miles above the town of Tain, and 11 miles distant from Portmahomac. The third station was at Bonar Quarry, marked C, situated on the north shore of the Firth, and 8 miles inland from Meikleferry; and the fourth station was at Bonar Bridge, marked D, one mile from the Bonar Quarry. Beyond Bonar Bridge the observations were also extended as far as the junction of the Rivers Oykel and Cassley, marked E, a distance of $12\frac{1}{2}$ miles; so that the whole distance embraced in the investigation was $33\frac{1}{2}$ miles. Graduated tide-gauges were fixed at Portmahomac, Meikleferry, Bonar Quarry, and Bonar Bridge; and by means of two distinct sets of observations, the levels of these gauges, in relation to each other, were accurately determined, so that all the tidal observations made at them could be reduced to the same *datum* line. The result of the observations was,

Low water line practically level from Portmahomac to Bonar Quarry. that the *low-water* of each tide is, *practically speaking, on the same level at Portmahomac, Meikleferry, and Bonar Quarry*. We use the word *practically*, because the level of the sea is more or less affected by every breeze of wind, which necessarily must *pen up* and elevate some portions of its surface, and cause corresponding depression, at other places, so that an unvarying low-water line will not be found to exist throughout a series of tides on any part even of the ocean itself; however limited the number of low-waters embraced may be. Accordingly, deviations from a truly level line of a few inches occasionally occurred in the observations made at the Dornoch Firth; but these were not of greater extent than could reasonably be traced to the effect of wind, and were found to vary, not only in their amount, but also in their value, being sometimes *plus* and sometimes *minus* quantities, causing corresponding variations in the results deduced from the different series of tidal observations that were made. Some of these showed the low-water within a fraction of an inch of being level; while others gave a notable *elevation* at some of the stations; and others, again, gave a *depression* below the level line at the very stations where previously there had been a rise.

To illustrate this more fully, we shall give a few examples: Thus, on the 23d of June (on which day the weather happened to be very calm), the level of low-water at Meikleferry was three-quarters of an inch *above* that at Portmahomac; and on the next day, the wind blowing fresh from the S.E., the level of low-water at Meikleferry was $3\frac{1}{2}$ inches *above* that at Portmahomac. Again, a succeeding observation gave the level of Meikleferry three-quarters of an inch *below* Portmahomac. In the same way, and in similar small degrees, the level between the low-water at Bonar Quarry tide-gauge and at Portmahomac was found to vary. The *average* of all the observations made, gave the level of low-water at Meikleferry 2.2 inches *above* that at Portmahomac, and the level of low-water at Bonar Quarry 1.1 inch *below*

the low-water at Portmahomac. Whether these *average* differences of level be traceable to the effects of prevailing winds, which may be supposed to have exerted a greater influence on the water at the more exposed stations, or to any inaccuracy in the levels, must evidently, from the examples given of the extent and nature of the daily deviations, be a point which we cannot determine; but the result of a lengthened train of observations, notwithstanding the *average* difference above stated, may fairly be held to be, that the low-water of each tide is *practically* on the same level at Portmahomac, Meikleferry, and Bonar Quarry; and therefore that the *low-water* tidal phenomena, throughout the whole extent of the firth, correspond with those of the sea.

But when the results of the observations at Bonar Bridge **Low-water rises from Quarry to Bonar Bridge.** come to be compared with those made at the seaward station, a very marked difference presents itself; for, while the low-water line is found to be practically level from Portmahomac to Bonar Quarry, a distance of 20 miles, throughout a narrow firth, varying from $1\frac{1}{2}$ mile to 550 feet in breadth at low-water, we find that between the Quarry and Bonar Bridge, a distance of only one mile, there is a rise in the low-water line of spring-tides of no less than 6 feet 6 inches. It was therefore concluded that, in the Dornoch Firth, the point at which the low-water level of spring-tides met the descending current of fresh water, lay somewhere between the Quarry and Bonar Bridge. A different series of observations was made to ascertain the exact point at which this junction takes place, and the result of these observations was, that at low-water of an ordinary spring-tide, rising 14 feet at Meikleferry, the low-water level of the sea meets or intersects the descending fresh-water stream from the Kyle of Sutherland, at a point 1700 yards below Bonar Bridge, or nearly opposite Kincardine Church, and within 60 yards of the Quarry station. Between this point and the bridge, a distance of 1700 yards, there is a rise of 6 feet 6 inches, giving an average slope on the bed of the river of 1 in 784, or 6.7 feet per mile.

In addition to this uniformity in the level of low-water, it was further found that the tidal phenomena of the firth corresponded to that of the adjoining sea, in the outline traced by the passage of the tidal wave, as deduced from observations made at the different stations on the rise and fall of the tide level between the periods of low and high water. During the period between each low-water or high-water the level of the surface was ever varying, there being no lengthened cessation of ebbing and flowing, the tide-wave being fully developed at the whole of the stations up to Bonar Quarry. The range of tide was indeed increased in the inner part of the firth to the extent of 9 inches at Meikleferry, and 12 inches at Bonar Quarry; that is, when the rise of tide was 12 feet 8 inches at Portmahomac, it was 13 feet 5 inches at Meikleferry, and 13 feet 8 inches at Bonar Quarry—an increase which is due to the momentum of the tidal wave when obstructed by the contracting shores of the firth, and is accounted for by the principle of the conservation of forces.¹

But if we inquire into the tides at Bonar Bridge, we find that **Rise of tide they do not correspond with those of the adjoining sea at Bonar the firth; for taking the tide to which we have already alluded, which rose 13 feet 8 inches at Bonar Quarry, it was found on the same day to rise only one-half of that amount, or 6 feet 10 inches at Bonar Bridge; the difference between the two results being occasioned by the rise on the low-water line of the channel between these two places.** The tide on the particular day alluded to rose no less than 6 feet 10 inches at Bonar Quarry before it attained the level of the low-water at Bonar Bridge, when it began to rise at that place also, and afterwards continued to flow nearly uniformly at

Rivers. both places. Fig. 1 is a diagram illustrative of the form of the tide-wave at Meikleferry and Bonar Bridge, the hard line represents the curve formed by the passage of the tidal wave at Meikleferry, and the dotted line shows that at Bonar

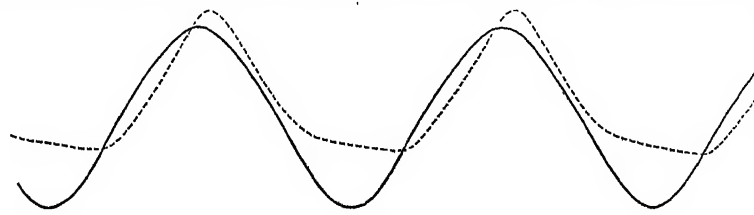

Fig. 1.

Bridge. In both cases the vertical space represents the rise of tide, and the horizontal space the elapsed time. From this diagram it will be seen, that while the tide at Meikleferry is symmetrical, and presents a constantly rising or falling outline, the tide at Bonar Bridge represents a long period, extending on some occasions by actual observation to several hours at low-water, nearly unaffected by tidal influence, during which period the water stood almost at the same level. The tidal water admitted into the upper part of the estuary above Bonar Bridge took a considerable time to drain off through the narrow water-way at that place, and hence the water did not attain a permanent low-water level, even long after the tide had ceased to operate in affecting its surface. The observations made to ascertain how far the tidal influence extended up the Kyles of Sutherland were conducted with the same care, and proved that the highest point influenced by the tide was at the junction of the Rivers Oyckell and Cassley, 12½ miles above Bonar Bridge.

Mean sea-level.

A further test of the "sea proper" will, it is believed, be found in the existence, at any place of observation within that compartment, of a central point in the vertical range of tide from which the high and low water levels of every tide are very nearly equidistant. The existence of such a point was, it is believed, first determined by Mr James Jardine at the Tay in 1810,¹ and has been observed in the firths of Forth and Dornoch, at the Skerryvore Rocks on the west of Scotland, at the Isle of Man, and in the Mersey. These different series of observations, made at points so far distant from each other, seem to prove the universality of the phenomenon, at least on the shores of this country. But in ascending into the tidal compartment, the rise on the low-water level, which has already been described, destroys at once the symmetry of the tide-wave, as shown in fig. 1, and the existence of any such central point equidistant from the high and low water level of each tide.

The case we have adduced will serve to illustrate the definition we have given of the compartments of rivers. From Portmahomac to Kincardine, near Bonar Quarry, we have all the evidences of what we have termed the "sea proper;" the line traced through the low-water mark at different parts of the firth is practically level; the curve formed by the rise and fall of the tide is symmetrical; there is no lengthened cessation of ebbing and flowing at the period of low water; and the range of tide is unmodified save by the additional rise due to the narrow frith through which the tide-wave passes. From Kincardine to the junction of the Oyckell and Cassley, we have proofs no less evident of the modified flow of the tide peculiar to the "tidal compartment." Even at Bonar Bridge, one mile above the quarry, the low-water level is 6 feet 6 inches higher than at the station below. At low-water the tide remains within a few inches of the same level for several

hours, and its maximum range is reduced to about one-half of what it is further seaward, while at the junction of the Oyckell and Cassley it disappears altogether. Above this point no tide is known to affect the flow of the stream, which, being free from all tidal influence, may be termed the "river proper."

We must here warn the reader not to suppose that the boundaries we have traced as existing in the Dornoch Firth, and many other places which the writer has investigated, may be determined with the same precision under all circumstances and in every case. The observations to which we have alluded, are supposed to be made

These boundaries as existing in the Dornoch Firth, and many other places which the writer has investigated, may be determined with the same precision under all circumstances and in every case. The observations to which we have alluded, are supposed to be made

at periods when the river is free from floods and the sea unaffected by heavy gales; moreover, the configuration of the bottom and shores of a river and estuary may, in certain cases, render the accurate determination of the boundaries very difficult. All that we assert is, that these compartments do in some measure, more or less defined, exist in all cases; and although not determined with the same careful precision as explained in the case of the Dornoch Firth, we have made observations of a more general character, and with complete success, to define approximately the tidal compartments in many estuaries and rivers in Britain and Ireland.

But there are other data with which the engineer must be furnished before he can advantageously consider the improvement of any part of a river. These data include the determination of its slope, velocity, and discharge, the nature of its bed and banks, and many other particulars. For full details as to the character and extent of such information, and the means of obtaining it, we can only refer the reader to works on the subject of River and Marine Surveying.² Neither do we include in the present treatise any sketch or digest, however brief, of the interesting and gradual progress made by philosophers and engineers of the early Italian and French schools, in the theoretical and experimental investigations of the laws which regulate the flow of water in natural and artificial channels, which investigations form the basis of all our practice in hydraulic engineering. These lengthened and laborious experimental researches will be found to be most fully discussed—historically, theoretically, and practically—in the valuable article by Dr Robison on the Theory of Rivers, in this Encyclopædia (see RIVER), and also in the report made by Mr George Rennie to the British Association on the progress and present state of our knowledge of hydraulics as a branch of engineering.³

Data required by the engineer.

While we do not therefore propose to advert at length either to the theoretical or practical details of the subject, still the whole of river engineering is so connected with, and dependent on, those physical characteristics of rivers which are termed the *slope*, the *hydraulic mean depth*, the *velocity*, and the *discharge*, that it seems to be indispensable to a proper understanding of the subject that these elements should be defined, and that the relations which subsist between them should be considered. The following definitions will suffice to answer the purpose in view:—

1. The *slope* is the fall on the surface of the river, which is generally expressed in feet or inches per mile.

2. The *hydraulic mean depth* is the quotient arising from dividing the sectional area of the channel in square feet by the wetted border or perimeter in lineal feet.

3. The *mean velocity* is that velocity which is common to the whole cross section of a stream, and is represented by the discharge divided by the area of that section.

Rivers.
Method of
ascertain-
ing dis-
charge by
measure-
ment;

4. The *discharge* is the quantity of water yielded by the stream in a given time, and is generally stated in cubic feet. In the practice of engineering it is frequently necessary to consider questions involving the relations which subsist between these different elements, and many formulæ have been proposed to facilitate this operation. The Chevalier Dubuat was the first investigator who, by discovering the effects of the friction of fluids on their own particles, and on the bed along which they move, was enabled to apply his theoretical knowledge of hydraulics to practical purposes, and his views and formulæ will be found fully discussed in the article RIVER already alluded to. The writer of this article has, however, found that such formulæ are not *generally* applicable, and it seems desirable to lay before the practical engineer the various results given by different formulæ when applied under the same circumstances, in order that he may be cautioned as to relying on such a means of computation in cases where great exactness is requisite. In order to ascertain the discharge of a stream or river, the writer has therefore in practice resorted to actual measurement. For this purpose, a situation was selected where the bed was tolerably uniform in its longitudinal and transverse outline. A correct transverse section of the bed or channel was made, and the section was divided into compartments. The surface velocity in the centre of each compartment was then taken by means of floats, or the instrument called the *tachometer*. These surface velocities were reduced to mean velocities for each compartment by Dubuat's formula:—

$$M = \frac{(\sqrt{V} - 1)^2 + V}{2}$$

or more simply, in cases where great accuracy is not required,

$$M = 0.8 V$$

where V = the observed surface velocity in inches per second.

M = the mean velocity in inches per second.

We have found by means of the tachometer, used at different depths, that this formula expresses accurately the mean velocity of *any vertical section* of the stream to which the observed surface velocity is applicable. But as the surface velocity on the same cross section is not uniform throughout the width of the stream, it becomes necessary, as already stated, to divide the section into compartments, so as to embrace the maximum and minimum speeds. The areas of the different sections being then multiplied by the corresponding mean velocities obtained by either of the above formulæ, the sum of the discharge due to the different compartments is held to give the total discharge of the stream or river. It is obvious that the accuracy of the result obtained by this process depends on the judgment with which the cross-sectional area is subdivided, and on the care with which the observations are made. The operation is, in many cases, attended with difficulties, and in all with a considerable consumption of time; and many formulæ have been proposed to shorten it. The writer has compared the computed discharge given by several of these formulæ with the discharge as ascertained by careful observations made in the manner described, and the following result is submitted for the information of engineers.

The formulæ subjected to trial were:—

I. Formula given by Dr Robison, founded on Dubuat's investigations:—

$$M = \frac{307 (\sqrt{d} - 0.1)}{\sqrt{S} - \text{Hyp. log. of } \sqrt{S} + 1.6} - 0.3 (\sqrt{d} - 0.1)$$

in which M = the mean velocity in inches per second,
d = the hydraulic mean depth in inches,
S = the reciprocal of the slope of the surface which is the denominator of the fraction expressing the slope, the numerator being always unity (a slope of 1 foot a mile is $\frac{1}{5280}$, therefore $5280 = \text{reciprocal for that slope}$),
Hyp. log. = the common log. of the number to which it is attached, multiplied by 2.3026.

II. Formula given by Sir John Leslie:—

$$M = \frac{1.5}{16} \sqrt{df}$$

in which M = the mean velocity in miles per hour,
a = the hydraulic mean depth in feet,
f = the fall on the surface in feet per mile.

III. Formula given by Mr Ellet for calculating discharge of the Mississippi:—

$$V = \frac{8}{10} \sqrt{df} + \frac{df}{20}$$

$$M = 0.8 V$$

in which V = the surface velocity in feet per second,
d = the maximum depth of the river in feet,
f = the fall on the surface in feet per mile,
M = the mean velocity in feet per second.

IV. Formula given in Mr Beardmore's tables:—

$$M = \sqrt{a} 2f \times 55$$

in which M = mean velocity in feet per mile,
a = hydraulic mean depth in feet,
f = fall per mile in feet.

V. In addition to these formulæ, the writer also subjected to trial the formula:

$$M = \frac{(\sqrt{V} - 1)^2 + V}{2}$$

in which M = the mean velocity in inches per second,
V = the maximum surface velocity in the axis of the stream in inches per second.

In order to compare these different formulæ, a very favourable situation was selected for ascertaining the discharge of a stream by careful measurements of its sectional area and of the velocities at different parts of its surface from the centre to either side, and the result gave a discharge of 1653 cubic feet per minute, which, from various measurements, the writer believes to be a very near approximation to the actual discharge. The slope was also accurately ascertained, and the following are the results:—

	Cubic feet.
Discharge from measurement as above, 1653 per minute.	
1st. By Robison's formula.....	2214 do.
2d. By Leslie's do.	2474 do.
3d. By Ellet's do.	2784 do.
4th. By Beardmore's do.	2335 do.
5th. By formula assuming the mean deduced from the centre surface velocity as the mean for the whole section ...	1950 do.

It will be seen from this statement, that none of the formulæ afford a near approximation to the discharge of the small stream to which they were applied.

Again, it was ascertained by the late Dr Anderson, after most carefully dividing the cross section into compartments, that the discharge of the main branch of the Tay at Perth was 147,391 cubic feet per minute.³ The writer has also ascertained the discharges, as calculated by the different formulæ as above, and the following are the results:—

and by formulæ.

Rivers.		Cubic feet.
	Discharge per measurement	147,391 per minute.
	1st by Robison's formula	153,632 do.
	2d „ Leslie's	166,134 do.
	3d „ Ellet's.....	122,002 do.
	4th „ Formula in Beardmore's tables	156,569 do.
	5th „ Formula assuming the mean deduced from the centre surface velocity as the mean for the whole section	179,237 do.

Formula generally applicable, but affording only an approximation. The result of these trials, and others which the writer has had occasion to make, is, that none of the formulæ that have been proposed will be found *generally* applicable. As it is often convenient, however, to be able to approximate to the velocity or discharge due to a given area and fall, the following formula may be applied, and will, in most cases, give a pretty near approximative result, viz. :—

$$x = \frac{y\sqrt{af}}{x \times 5280}$$

$$z = \frac{60}{D}$$

in which x = the mean velocity of the whole section of the stream in miles per hour,
 y = a quotient which is found to vary from 0.65 for small streams under 2000 cubic feet per minute, to 0.9 for large rivers, such as the Clyde or the Tay,
 a = the hydraulic mean depth in feet,
 f = the fall on the surface in feet per mile,
 z = the mean velocity of the whole section of the stream in feet per minute,
 s = the sectional area of the stream in feet; and
 D = the discharge in cubic feet per minute.

It must still be kept in view that the application of any known formula to the determination of the mean velocity and discharge of a river is shown, by experimental inquiry, to afford only a rough approximation; and that if a near approximation is required, it must be obtained by means of observations embracing the velocities at different parts of the cross-sectional area, made in the manner already described.

Result of formula destroyed where under-currents exist.

We must offer the further caution, that those rules whereby the mean velocity is deduced from, or is assumed as bearing any constant ratio to, the surface velocity, do not apply in many situations which are within the influence of the tide. As will be explained more fully hereafter, the fresh water of the river being specifically lighter, is to a certain extent borne up by and floats upon the denser water of the sea. In surveying the Dec at Aberdeen in 1810, Mr Robert Stevenson found that, while there was an *outward* upper-current of fresh water, there was an *inward* under-current of salt water; so that, although the upper stratum was constantly running toward the sea, there was a regular rise and fall of the surface produced by the influx of the tidal waters below. Another instance of such an under-current, though not occasioned by the presence of a river, was found to exist in a marked degree at the Cromarty Firth by Mr Alan Stevenson in 1837. The waters of the Cromarty Firth pass to and from the sea through the narrow gorge between the Suters of Cromarty, where the width is about 4500 feet, and the depth about 150 feet. The mean velocity due to the column of water passing this gorge, as deduced from the observed surface velocity, was not sufficient to account for the quantity of water actually passed during each tide, as determined by measuring the cubical capacity of the basin of the firth. This led to the observation of the under-currents through the gorge by means of submerged floats, and it was found that during flood-tides the surface velocity was 1.8 mile per hour; while at the depth of 50 feet the velocity was not less than 4 miles per hour, being an increase of 2.2 miles per hour. During ebb-tide the surface velocity was 2.7 miles per hour, and at 50 feet it was not less than 4.5

miles per hour, being an increase of 1.8 mile per hour. The existence of these under-currents is due to some obscure causes connected no doubt with the configuration of the bottom, and the circumstances under which the tidal wave approaches and recedes from the shore. The existence of a powerful oceanic under-current during the flood-tide may account for the increased under-velocity of the tide flowing into the Cromarty Firth; and if we suppose a similar rapid under-current to sweep along the coast during the ebb-tide, the tendency would be to draw off the water more quickly from the lower part of the channel between the Suters which forms the mouth of the firth, and thus to increase the velocity at and near the bottom during the ebb-tide, as also indicated by the observations to which we have alluded. It is evident that in all such situations the application of a *common* or *mean* velocity, deduced from the observed surface velocity, cannot be relied on as correct.

As the slopes, velocities, and discharges of rivers are so important in all matters connected with the flow of streams, and may be useful for comparison in considering questions of river engineering, we give at the end of this article, in a tabular form, the physical characteristics of different rivers, embracing all the information we have been able to collect, with the sources from whence that information was obtained.

We have considered it necessary to enter thus far into detail, to prepare the way for what is to follow,—*First*, Because it is quite impossible to consider and design with advantage the improvements of a river without a correct knowledge of its physical characteristics, as developed in the course of such investigations as we have described. Such information cannot in every case be procured with an equal amount of precision, but the more complete and detailed it is, the more confidently and advantageously will the engineer proceed to form his design. *Secondly*, We have been particular in defining the physical boundaries of rivers, because the remedial means which call for the engineer's consideration in designing improvements on the three compartments which they include, are not less distinct than the different phenomena which have been described as their peculiar characteristics. In proof of this, it may be stated generally, that the works on the “river proper” section consist chiefly in the erection of weirs, by means of which the water is dammed up so as to form stretches of canal in the river's bed, with cuts and locks between the different reaches. The “tidal compartment” embraces a more varied range, including the straightening, widening, or deepening of the courses and beds of rivers, the formation of new cuts, the erection of walls for the guidance of tidal currents, and in some cases the shutting up of subsidiary channels; while the “seaward compartment” embraces all works connected with the improvements or removal of bars and shoals.

On these subjects we shall have to enter at some length; and in treating of them it may be most convenient to consider the question of river navigation under the three following sections, viz. :—

- 1st. The upper compartment, or “river proper.”
- 2d. The intermediate compartment, or “tidal river;” and
- 3d. The lower compartment, or “sea proper.”

SECT. III.—THE “RIVER PROPER” DEPARTMENT.

The magnitude of a river is, under certain conditions, proportional to the extent of country which is drained, Sizes of rivers proportional to extent of country drained. as will be seen by reference to the table at the end of this article, and all our ideas regarding rivers, as affording the means of inland navigation, must necessarily be to some extent varied to meet the different physical characteristics of different countries. Thus, in continents we find rivers of great magnitude, fed by the drainage of vast tracts of surrounding land, rolling their contents in a broad, deep current to the

Rivers.

ocean, and affording a highway for vessels of the largest class to pursue their course for hundreds of miles into the interior of the country. Of such is the Mississippi, which, according to Mr Ellet, maintains, for a distance of nearly 1200 miles above New Orleans, an average breadth of 3300 feet, and a depth of 115 feet. The Ohio, which joins it at this place, is navigable to Pittsburgh, where the writer of this a title has seen from thirty to forty large-sized steamers lying at the quays of that truly inland port, which were all engaged in trading to New Orleans, on the Gulf of Mexico,¹ being a river navigation of upwards of 2000 miles.

In considering the improvement or maintenance of such a navigation as this, the engineer has to deal chiefly with the control of the discharge due to the rains of the district through which the river flows. His difficulty does not so much consist in deficient depth or breadth of navigable channel, as in the magnitude of the floods with which he has to contend, and the provision he has to make for retaining them within such limits as to secure the safety of the surrounding district.

In less extended tracts of country the rivers are proportionally smaller; and when we come to consider our own island, we find that its area and drainage are altogether insufficient to afford depth and breadth of water for extended inland navigation. This will readily be understood when the areas of the basins and the discharges of some of our largest rivers are compared with the Mississippi, to which we have alluded. For example, according to the table to which we have already referred, the Tay drains 2283 square miles, and discharges 274,000 cubic feet per minute; the Clyde drains 945 square miles, and discharges 48,000 cubic feet per minute; the Mississippi drains 1,226,600 square miles, and discharges 76,800,000 cubic feet per minute.

The Mississippi.

It will not, we believe, be considered inappropriate to the subject we are discussing, to offer a short sketch of what is undoubtedly the most gigantic river navigation in the world, taken from the elaborate work by Mr Charles Ellet, on the Mississippi and the Ohio. It appears, from the information given in that work, that the Mississippi varies from 2200 to 5000 feet in width, the average width being assumed as 3300 feet. It is from 70 to 180 feet in depth, the average being 115 feet. The area of the cross section varies from 105,544 square feet to 268,646 square feet, the average being 200,000 square feet. The length, from its junction with the Ohio to the Gulf of Mexico, is 1178 miles, and its average descent at full water is $3\frac{1}{2}$ inches per mile, and in absence of floods (or during summer and autumn) $2\frac{1}{2}$ inches per mile. The length of the Ohio, from its junction with the Mississippi to Pittsburgh (the head of the navigation for large vessels), is 975 miles, and the average inclination is about $5\frac{1}{2}$ inches per mile. From Pittsburgh to Olean Point the distance is 250 miles, and the inclination 2 feet 10 inches per mile. When the water is high, steamboats have ascended to Olean Point, which is 2400 miles from the Gulf of Mexico; and in doing so, have had to overcome a current which at some places runs with a velocity of 5 miles per hour. This, however, is chiefly in the upper part of the river. Generally speaking, vessels have no difficulty, in the lower or more open part of the stream, in avoiding the strength of the currents by keeping in-shore. But in the Ohio much inconvenience is felt during dry seasons from the currents at certain parts of the river; and the writer has seen a steamer, when deeply loaded, unable to overcome them until assisted by a warp attached to an anchor dropped ahead of the vessel, in the middle of the channel, by which, after considerable detention, she was "warped through the rapid." The discharge of the Mississippi is computed by Mr Ellet, at high

water, at 1,280,000 cubic feet per second; and its drainage he estimates at 1,226,600 square miles. When the autumnal rains set in, the river rises above its summer level to the enormous extent of about 40 feet at the mouth of the Ohio, and 20 feet at New Orleans. In investigating the physical characteristics of this mighty stream, Mr Ellet found—1st, That the average surface velocity in the centre of the river was 5 miles per hour, and occasionally the speed reached 7 miles per hour; 2d, By using under-current floats, he found that the speed of a float, supporting a line of 50 feet long, was always greater than that of the surface float—the average increase of velocity being 2 per cent.; 3d, The results of the experiments made, lead him to conclude that the mean velocity of the Mississippi is about 2 per cent. greater than the mean surface velocity; 4th, In coming to this conclusion, no account is taken of such observations as show remarkable under-currents, the velocity of which were in some places found to be 17 per cent., and $20\frac{1}{2}$ per cent. greater than the surface velocities; 5th, While the mass of water which the channel of the Mississippi bears is running downwards with a central velocity, the current next the shore is sometimes found to be running upwards, or in the opposite direction, at the rate of 1 to 2 miles per hour; 6th, While the water is running downwards in the one side of the river, it is often found with an appreciable slope, and visible current running upwards on the other side of the river; 7th, The surface of the river is therefore not a plane, but a peculiarly complicated warped surface, varying from point to point, and inclining alternately from side to side. After considering all the conflicting results derived from his investigations, Mr Ellet, in order to obtain the mean velocity and discharge of the river, employed the formula as already noticed,—

$$V = \frac{8}{10} \sqrt{df + 20}$$

$$M = 0.8 V$$

$$\text{and } Ma = D$$

where V = the velocity of central surface current in feet per second,

d = maximum depth of river in feet at place of observation,

f = slope of surface in feet per mile,

M = the mean velocity in feet per second,

a = area of cross section of river in feet,

D = discharge of river in cubic feet per second.

In discussing the various formulae for velocities and discharges, we have seen that the formula applied to the Mississippi by Mr Ellet does not apply to such rivers as the Tay, or to smaller water-courses; and until the result which he has given has been compared with the discharge obtained by actual measurement of the velocities at different parts of the cross section, we do not think that the discharge of the Mississippi, which has been calculated by Mr Ellet, can be relied on as accurate.

The chief object of the investigations made by Mr Ellet was the prevention of floods, which have recently increased both in number and extent. This he attributes—

First, To extended cultivation, by which evaporation is supposed to be diminished, the drainage increased, and the floods hurried forward more rapidly into the country below.

Secondly, To the extension of the embankments along the banks of the Mississippi and its tributaries, by which water that was formerly allowed to spread is now confined to the channel of the river.

Thirdly, To what are termed cut-offs, or straight cuts, by which the distance is shortened, and the slope and velocity increased, so that the water is brought down more rapidly from the country above.

¹ Sketch of Civil Engineering of North America, by David Stevenson, C.E.

Rivers. *Fourthly*, To the gradual extension of the delta into the sea, so as to lengthen the lower course of the river, to diminish the slope and velocity, and thus to throw back the water on the land above.

The works suggested for protecting the country against floods are—

First, More sufficient embankments.

Second, The prevention of further cut-offs, or works for straightening the upper parts of the tributaries of the river.

Third, The enlargement of the seaward channels or outlets; and

Fourth, The creation of large artificial reservoirs, by placing dams across the outlets of the lakes or distant tributaries, so as to compensate for the loss of the natural overflow of the water, which is checked by the embankments for protecting the country in the lower part of the river.

Danube.

An interesting account has been given by Mr Shepherd¹ of certain improvements on the Danube, to which we shall very shortly refer. The navigation of that river was greatly impeded by the constant shifting of its course after every flood. Its channel was divided into numerous branches, and the main object of the improvements was to shut off these lateral branches, and to cause the river to flow in one central channel. This was effected by means of a series of spurs or jetties, made of bundles of brushwood, and thrown out from either side of the river. The brushwood was laid down in its green state, and, taking root, each spur or jetty, after a few years, formed a thick massive hedge, which now prevents the stream from making further ravages on the banks, and confines it to one central channel, scouring out a depth sufficient for navigation. This system of embanking with faggots has been, according to Mr Shepherd, the means of rescuing thousands of acres of land on the Danube, at a cost of not 1s. per acre. These improvements have, it appears, been effected in what were the most dangerous parts of the river, and have, it is stated, in connection with an improved organization of pilotage, been of great benefit to the traffic of the Danube, which is now carried on almost uninterruptedly, it being a very rare occurrence to hear of any of the steamers getting aground.

Circumstances of the Mississippi not applicable to this country.

Although it has been considered proper to allude thus briefly to the large continental rivers, yet it will be obvious that the magnitude of such a river as the Mississippi, for example, prevents us from applying the special results and observations of Mr Ellet to rivers in this country. Indeed, the fresh-water or upper compartments of our rivers are so small, and their navigation is so limited, that we have little to say under that head which can be applicable to the British Isles.

Means of rendering our rivers navigable.

Our streams cannot, like the Mississippi or other large rivers, be advantageously navigated in their natural state; and the means employed to render them navigable may be said to consist in throwing dams across their beds, so as to convert them into a succession of narrow lakes or pools, in which the water is dammed up to such a height as to afford sufficient depth for small boats.

Old stanches.

In early times this was effected by means of what were called "stanches." Sir William Cubitt states that when he undertook the improvement of the Stour in Essex, there were thirteen stanches along the course of the river. These stanches consisted of two substantial posts, which were fixed in the bed of the river, at a sufficient distance apart to permit a boat to pass easily between them, and connected at the bottom by a cross cill. Upon one of these posts was a beam turning on a hinge or joint, and long enough to span the opening. When the "stanch" was used, the boatmen turned the beam (which was above the level of the water) across the opening, and placed vertically in the stream a

number of narrow planks resting against the bottom cill and the swinging beam, thus forming a weir which raised the water in the stream about 5 feet high. The boards were then rapidly withdrawn, the swinging beam was turned back, and all the boats which had been collected above were carried by the flow of water over the shallow below. By repeating this operation at given intervals, the boats were enabled to proceed a distance of about 23 miles in two or three days.

Rivers.

This primitive system, which was at one period very common in England, has been superseded by throwing permanent dams across the river, so as to convert its channel into a series of deep-water reaches, and the boats pass from one reach to the other by means of side-cuts with locks. The same plan has been extensively carried out in many of the smaller rivers in America, and is there called "still-water navigation." It has been executed on a pretty large scale by Sir William Cubitt on the upper part of the Severn, where the river has been divided into four reaches, having a depth of 6 feet, with side-cuts and locks having a lift of 8 feet each. The difficulty attending such an operation is the impediment which the weirs present to the passage of the river during floods; but in the case of the Severn this difficulty seems to have been overcome. Sir William Cubitt says the object of these weirs was to raise the water, and to retain it at a proper height for the navigation of the shallow parts of the river, without opposing such barriers as should prevent the free discharge of flood-water; and that this end has been completely answered, there being a depth of 6 feet of water at all times where there was formerly only a depth of 18 inches, and during floods the back-water does not rise higher than before the establishment of the weirs. A similar result may, he believes, be always attained by making the obliquity of the weirs sufficiently great.² The same system has also been adopted by the late Mr Rendel and Mr Beardmore, for the improvement of the navigation of the River Lea, an account of which has been communicated by Mr Beardmore to the Institution of Civil Engineers.³

The arguments, however, against canals, in consequence of the greater facilities afforded by railways, seem to apply with equal force to the upper compartments of rivers with their dams and locks; and as it is not likely that such a system of inland navigation will receive much extension, we shall, without further detail, proceed to consider tidal navigations which are more intimately connected with the commercial interests of the British Isles, and consequently occupy a more important position in the hydraulic engineering of this country.

SECT. IV.—TIDAL COMPARTMENTS OF RIVERS.

It is perhaps necessary to preface our observations on this branch of the subject by explaining what is implied by "tidal navigation," as distinguished from such large fresh-water streams as the Mississippi, or those smaller streams forming the upper compartments of our own rivers, both of which we have been considering. In the former case we saw that the art of navigation is most successfully and extensively practised on the fresh-water streams of the large continental rivers; while in the latter case it was shown that even by the aid of artificial weirs and locks, the largest rivers of this country could only be made navigable for vessels of the smallest class. We learn from this, as has also been stated, that the comparatively limited extent of our isolated country does not afford sufficient area for the collection of so large an amount of rain and spring water as to render our fresh-water streams available for the purposes of navi-

³ *Ibid.*, vol. xiii., p. 241.

Rivers.

Its importance.

Its extent modified by circumstances.

The object of all improvements is to increase it.

The tidal wave.

gation. The amount of fresh water which they discharge varies as the river floods rise and fall; and even at its maximum its effects in the lower portion of our estuaries is but feebly felt, as more fully explained hereafter in section vi., under the head of "*Bars*." Our rivers, indeed, may be regarded simply as creeks or inlets, formed and kept open, not by the fresh-water stream alone, but mainly by the action of the tide; and may be said to be navigable only when their channels are filled by the influx of water from the ocean. The great agent, therefore, in keeping open and deepening our navigations is to be found in the tidal flow, which not only scours and maintains the sea channels of our rivers, but also increases their depth of water. Nor is this all: another most important advantage derived from the tides is that upward current due to the tidal rise, which, at first checking and ultimately overpowering and reversing the flow of the ebb-stream, carries vessels to their port, far, it may be, into the interior, without the aid of either steam or wind. This is a view of the subject which cannot fail to strike even the most superficial observer, when he sees, on the Thames or Mersey, for example, a vast fleet of vessels of all sizes, and from all countries, hurried on by the silent but powerful energy of the flowing tide. How invaluable is such an agent to the commercial interests of this country! If, indeed, the action of our river-tides were suspended, it might truly be said of the steam power employed on our railways, that its occupation would be gone. Nor need we do more to enforce the wide-spread interests of the subject than remind the reader that the ports of London, Liverpool, and Glasgow, not to name less important places, are entirely dependent on tidal navigation for their existence.

From what has been said as to the physical boundaries of rivers, it will be apparent that the extent to which this tidal influence is felt varies in different situations. Where the slope of the river is gentle, and the channel is comparatively clear and unobstructed, it is felt far up the river, as in the case of the Thames, where it reaches Teddington Weir, 65 miles from the Nore; and in the Tay, where it reaches its junction with the Almond, 35 miles from the bar. In other cases, such as the Lune in Lancashire, or the Dee in Cheshire, the tidal flow is suddenly checked by artificial weirs erected in the bed of the river for the supply of mills. In a third class of rivers the upward flow of the tide is almost neutralized by the existence of natural obstructions, as in the case of the Erne at Ballyshannon, where it flows only about 3, and the Ness, where it flows only about 6 miles up the river.

Now, the great object of the engineer, in dealing with what we have termed the "tidal compartment of a river," is to increase the *tidal influence*, or, in other words, to facilitate the *propagation of the tidal wave* through the estuary or river for which he has to design works, and it will be found in the examples we have hereafter to offer that, with proper management, this desirable improvement may be surely accomplished, and its amount accurately determined. But that the subject may be fully understood, it is necessary that we should in the outset explain the nature and laws of "tidal propagation" and "tidal currents"—phenomena attending the tides of our rivers and estuaries which must be duly recognised and estimated in all designs for improvements which are based on sound principles of river engineering.

The tidal wave which enters an estuary is a branch of the great tidal wave of the ocean. Mr Scott Russell was the first experimental inquirer who conducted investigations on the tide wave of estuaries. Mr Russell's observations were made on the Dee in Cheshire, and the Clyde, and the results which he obtained may be briefly stated as follows:—

1. The great primary wave of translation differs from every other species of wave in its origin, its phenomena, and its laws.

2. The tide wave is *identical* with the great primary wave of translation.

3. In a rectangular channel, the velocity with which the tidal wave is propagated is equal to the velocity acquired by a heavy body falling freely by gravity through a height equal to half the depth of the fluid, reckoned from the top of the wave to the bottom of the channel. In a sloping or triangular channel the velocity is that of a gravitating body due to $\frac{1}{3}$ d of the greatest depth. In a parabolic channel the velocity is that due to $\frac{2}{3}$ ths or $\frac{3}{4}$ ths of the greatest depth, according as the channel is convex or concave. And generally *the velocity is that due to gravity, acting through a height equal to the depth of the centre of gravity of the transverse section of the channel below the surface of the fluid*.

4. The velocity in channels of uniform depth is independent of their breadth.

5. A tidal *bore* is formed when the water is so shallow that the first waves of flood move with a velocity so much less than that due to the succeeding parts of the tidal wave as to be overtaken by the subsequent parts, or whenever the tide rises so rapidly that the height of the first wave of the tide exceeds the depth of water at that place.

6. A wave of high-water of spring tides travels faster than a wave of high-water of neap tides.

These laws are supposed to apply to the passage of the wave through channels having a pretty uniform depth and form of cross section; but the very irregular outline of the beds of most of our tidal channels renders it almost always difficult, and in many cases impossible, to apply them rigidly to cases which occur in actual practice. The writer may, however, state generally, in corroboration of the correctness of Mr Russell's deductions, that after investigating the tidal phenomena of many estuaries and rivers, he has found that in all cases the quickest propagation of the tidal wave occurs at those places where there is the greatest average depth; but the varying outline of the cross section renders it almost impossible, in most cases, to determine what is the *ruling depth* for calculating the rates of propagation in any particular section of the river. In the Dornoch Firth, to which we have already alluded, the writer found that the distance of 11 miles between Portmahomac and Meikleferry is traversed by the tide-wave in thirty minutes, giving a velocity of 22 miles per hour. The depth of the water of that part of the firth varies from 9 to 50 feet. Between Meikleferry, again, and the Quarry, a distance of 8 miles, where the depth is much less, varying from 6 to 20 feet, the transit of the wave occupies 65 minutes, giving a speed of 6.4 miles per hour.¹ Between the Quarry and Bonar Bridge, a distance of 1 mile, the water is comparatively shallow, varying from 1 to 3 feet, and the rise on the bed of the river is very rapid. In consequence of these obstructions, the tide does not appear at Bonar Bridge for an hour and a half after it has appeared at the Quarry, giving a rate of propagation of only two-thirds of a mile per hour. From observations made by the writer at the Dornoch Firth and elsewhere, it appears evident that, in addition to the elements on which the laws of propagation as quoted are based, the slope on the surface of the stream in tidal rivers affects to some extent the rate of propagation, independently either of the depth or cross-sectional form of the channel; but it will be more convenient to notice this at a subsequent part of this treatise.

Now, the obstructions which are most frequently found to operate as retarding influences are, the circuitous routes of the channels of rivers, inequalities in their beds, the pro-

Rivers. section of obstacles from their banks, and in certain circumstances the slopes of their surfaces. The combined effect of these obstructions is such as in all rivers to check the propagation of the tide-wave; and in situations where there is a great and rapid rise of tide, to heap up the water in the lower part of the river, and so to occasion what are termed "bores," and other apparent anomalies. In the Dee, for example, there is at low-water a fall of 11 feet from Chester to Flint, a distance of 12 miles; and on one occasion the writer found that after the tide had risen 18 feet 4 inches at Flint, it had not commenced to flow at Chester. While, therefore, at low-water there is a fall seawards of 11 feet from Chester to Flint, there was at the time alluded to a fall from the sea downwards, so to speak, of no less than 7 feet 4 inches from Flint to Chester. Fig. 2 is a diagram

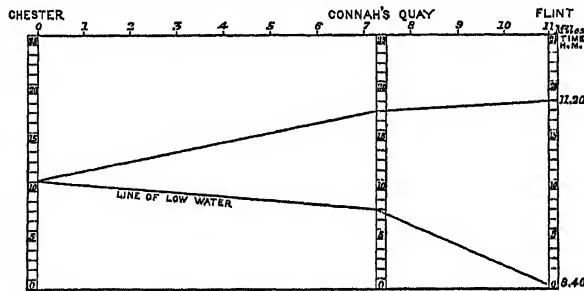

Fig. 2.

of these tide lines, which will illustrate more clearly the effect of this heaping up of water in the seaward part of the river. The lower line represents the surface of low-water, and the upper line shows the surface at the period of flood-tide to which we have alluded.¹ In this case the small depth of water, and tortuous and unequal channel, retarded the early waves of flood-tide so much, that they were overtaken by the succeeding waves; and, in accordance with Mr Russel's theory, a *tidal bore* was the result, or, in other words, the water was heaped up so high, and the slope was consequently so great, as to cause the water

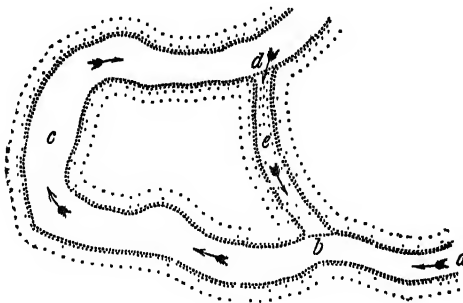

Fig. 3.

to tumble over, and ascend the river in the form of a breaking wave.

The manner in which such tides flow up an estuary may be explained by a simple illustration. In fig. 3 the letters *a, b, c, d* represent a part of the low-water channel of the River Example Dee, at a place where the estuary is about 3 miles wide, and consists of extensive sand-banks. In examining minutely the windings of the stream in reference to certain investigations, it was necessary to walk down the right bank of the river at low-water, close to the edge of the channel. While so engaged, the writer crossed at the point *b*, a hollow in the sand-bank, which, though depressed below the general height of the surrounding surface, was nevertheless quite dry, the lowest part of the track being considerably above the level of the water of the river. Crossing this hollow, the noise of the approaching tide was heard; and expecting to meet the flood forcing its way up the river, he continued to walk on; but seeing no appearance of its approach by the proper channel, and still hearing the noise gradually increasing, and apparently coming from behind, he turned round and perceived a rapid run of water flowing (in the direction shown by the arrow) through the hollow *deb*, which had just been crossed, and emptying itself into the river at *b*. He immediately hastened back, and after having waded through the newly-formed stream at *b*, which had attained a depth of 6 or 8 inches, he remained on its upper side to see the result of this unexpected inroad. The water continued to rush through the hollow, rapidly gaining breadth and depth, and at last, after an interval of 2 or 2½ minutes from the time at which the noise was first heard, the tide appeared forcing its way up the proper channel of the river with a head or bore of 6 or 8 inches in height. In this case it is clear, from what has been said as to the slope on the river from Flint to Chester during the early periods of tide, that the level of the water at *d* in the diagram would be above that at *b*. The tide, on arriving at the point *d*, would be naturally divided into two branches or currents, one proceeding up the natural channel towards *c*, and the other flowing into the hollow in the sand-bank at *d* towards *e*; and as the level of the water at *d* rose, the stream which flowed into the hollow in the sand-bank would gradually rise higher until it surmounted the summit-level at *e*, after which it would rush from *e* to *b* without obstruction. The other branch of the tide would in the meantime be forcing its way along the circuitous channel *deb*, which was about a mile in length; and before it reached *b*, the water at *d* had attained a much higher level than at *b*, and having surmounted the summit-level of the sand-bank at *e*, continued to flow without obstruction into the channel of the river in the manner represented. Thus in all places where the retarding influences which exist in the regular channel of the river exceed the obstructions in any *back lake* or *swash-way*, the tide will flow sooner through the latter than the former, and give rise to an apparent anomaly such as has been described.

The late Admiral Beechey, in his *Remarks on the Tidal Bore on Phenomena of the River Severn*, published in 1851, gives the Severn.

¹ The writer has found, that in all cases the heaping up of the water increases with the rise of tide, being greatest in spring and least in neap tides; as will be seen from the following tabular views of the maximum difference of level between the surface of the water at Flint and Chester on the Dee, and (to offer another example) at Glasson and Lancaster on the Lune, during the flow of tides of various amounts of vertical range.

Rivers.

the following interesting account of the bore on that river:—"The bore," he says, "is not dangerous to boats if afloat in the middle of the river; and it is the common practice up the Severn to row the boats out to the centre of the stream on the approach of the bore, and put their head to the wave; but if this precaution be not taken, and the boats are allowed to remain at the edge of the shore, they are liable to be swamped or stove, as the waves break with great violence along the banks as it proceeds; but towards the centre of the river, if the water be not very shallow, the wave is smooth and unbroken. Before the arrival of the bore, the stream runs down the river, and the altitude of the water at a distance from the sea is quite stationary; but on the arrival of the bore, the water instantly rises according to the height of the breast of the wave, and the stream turns and follows the wave up the river, although it had but a few minutes before been running down at a rapid rate; and this change of stream is effected without any breaking wave. When there is a heavy fresh down the river, and the stream is running at the rate of four or more miles an hour, the upward stream hangs for several minutes after the bore has passed, not being able to overcome at the moment the impetus of the ebbing water; but when it has once turned upwards, it attains its maximum speed in the first half hour of the tide. When the reaches of the river are straight, the bore travels evenly up the river, but at the turnings it is thrown off towards the further side, where it rises higher than in the straight reaches; thence it recoils and impinges upon the opposite shore, and so, like a disturbed pendulum, it oscillates from side to side, and only regains its steady course when the reaches lengthen. The highest tide of the year rolled up the Severn on the 1st of December. There was about 2 feet of water above the ordinary summer-level in the river, and the morning was calm and favourable to the phenomenon. The stream at low-water ran down at the rate of $2\frac{1}{2}$ miles (geographical) per hour, until the time when the bore came rolling up the river with a breast from 5 to 6 feet high at the sides, and 3 feet 6 inches in the centre. The wave was glassy smooth; and as it advanced towards a spectator stationed at Stonebench, a singular effect was produced by the distorted surface of the wave reflecting the rising sun, and brilliantly illuminating the stems and branches of the wood skirting the river as the bore passed along—an effect which greatly enhanced the interest of the phenomenon, which is at all times an object of curiosity. The stream turned up the instant after the bore passed, and ran at the rate of $3\frac{1}{2}$ miles per hour, which was about half the average rate of the bore, the speed of which varied from 12 to 7 miles per hour, averaging 8 between Stonebench and Gloucester." Admiral Beechey further says, "that the effect of a fresh, or a certain depth of water in the river, upon the advance of the bore is remarkable. At dry periods the great obstruction to the progress of the bore lies between Sharpness and Bollowpool, and at such times the many dry sand-banks prevent the bore attaining a rate greater than about 4 miles an hour; but when the river is under the influence of freshes, and the water raised and covering some of the banks, it appears to roll on at a rate of 10 miles an hour in opposition to the stream, which runs down at the rate of upwards of 4 miles an hour."

Tide currents.

But the passage of the tidal-wave through an estuary or river, must not be mistaken for what is called the "tide current," which is a totally different phenomenon. The tidal-wave which we have been describing as passing through the lower part of the Dornoch Firth, for example, at the rate of 22 miles per hour, is not the current due to the flowing tide by which vessels are carried across the

bar, and borne onward to their destination. That current flows with a velocity which at the Dornoch Firth does not exceed 4 or 5 miles per hour; a velocity which, indeed, is not often exceeded, excepting in such rapid tideways as the Severn, at the New Passage, where the velocity is said to reach 9 miles per hour;¹ and in the Pentland Firth, where Captain Otter measured a velocity during ebb-tide of no less than $10\frac{1}{2}$ th nautical miles per hour,² being, so far as we know, the greatest tide velocity on record. The laws of the propagation of the tidal wave, to which we first alluded, depend, as explained, on circumstances somewhat obscure; but the velocity of the tide current, or that current which flows into our rivers, and affects the transit of shipping, is due *entirely to the slope or fall on the surface of the water*. The amount of this slope has been shown to be dependent on the rapidity with which the tide rises, and the amount of obstruction presented to its propagation up the river. The more rapid the rise of tide, and the greater the obstruction to its flow, the higher will the tide-wave at certain parts of a river or estuary be heaped up. A head of water is thus formed whose height is due to the rapidity of the rise of the tide and the obstruction to its progress; and a flow of water having a velocity due to that head is generated up the river or estuary, and this flow of water is what we term the *tide current*.

This is probably the most convenient place to notice some facts of great importance in river engineering, which we deduce from these considerations, as to the nature of the tidal propagation and tide currents. The obstructions to which we have alluded *retard* the rate of propagation, but by raising the head, they *increase* the velocity of the tide currents. Now, as the aim, and, if successful, the effect of all engineering works, is to increase the rate of tidal propagation, no less certainly will they tend to lessen the heaping up of water in the lower reaches, and at the same time to *decrease the velocity of the tide currents*. In cases where these currents are found to act prejudicially by producing a bore, or by bringing up sand from the lower parts of the estuary, or where they are inconveniently rapid for navigation, we are thus, while increasing the propagation of the tidal wave, enabled to check their energy, and thus to effect an important improvement.

Another important circumstance is worthy of notice at this place. It is well known that the momentum of the column of water, flowing up the gradually contracting and rising channel of a river, causes the level of high-water to stand higher than in the open ocean or in the lower reaches. This is accounted for, as already stated, on the principle of the conservation of forces. The height to which the water is thus raised depends on the quantity of water thrown in by the tide during a given time, the elevation being greatest at spring, and smallest at neap tides. At the Dee, for example, the writer found that the high-water of spring tides at Chester was 14 inches higher than that at Connah's Quay; while at neap tides the difference of level was only 4 inches. Now, the effect of engineering works, as will be more fully detailed hereafter, is not only to produce a free propagation of the tide, but to admit a larger body of tidal water; and it has been contended that such operations must necessarily cause the tide to rise higher, and it has been attempted to be shown that they might in some situations occasion inconvenience, and even injury to property, in consequence of the overflowing of the river's banks. After the most careful observation, however, the writer has not been able to detect that such operations have in any case had the effect of appreciably raising the level of the high-water line. Although the tide in improved rivers begins to flow earlier, and a much larger body of

Rivers.

² Admiralty Survey of Pentland Firth, by Captain Otter, Admiralty coasting pilot.

Rivers.

water is thrown up the river, still, in conformity with the views already stated, the velocity with which the water flows is decreased, so that the momentum of the column of water remains nearly the same, or at least is not so notably altered as sensibly to increase the height to which the high-water rises; and by this fortunate compensative action our rivers, though their beds are opened up and improved, do not inundate our towns or even overflow our quays, but quietly keep within their original limits.

Removal
of obstruc-
tions to
tidal flow.

The removal of all obstacles to the flow of the tide is the object, as already stated, to which the engineer has chiefly to direct his attention in designing improvements in the department of navigation now under consideration; and it may be stated, that in order to form a satisfactory opinion on this matter, it is essential to have an accurate survey, showing the depths of water and the breadths of channel throughout the whole extent of the river, and also to ascertain the amount of tidal range, the velocity of the currents, the rise on the bed, and the nature of the materials of which the bottom and banks are composed. Possessed of this information, he is in a position to consider to what extent the bed of the river may with advantage be deepened and widened, and the currents directed by means of walls; also if subsidiary channels may with safety be shut up, or new cuts be made for the passage of the river, or whether or not irregularities in the width which injuriously affect the currents may be corrected. In all these matters the engineer must, in each particular case, be guided by experience. While it is therefore impossible, in such circumstances to specify works which shall be of *universal* application, it is nevertheless quite within the range of sound engineering advice to point out *generally* the works which are most likely to effect improvements, and to direct the reader to cases in which such works have proved successful; and this is all that we propose to do in the remarks we have to offer on this part of our subject.

With reference to these operations, then, it may be stated, that all obstructions which prevent the extension of the tidal influence up the river may safely be taken away, and their removal may confidently be expected to be followed by highly beneficial effects. It is necessary to remark, however, that the removal of artificial weirs erected for the purposes of manufacture is, in many cases, attended with difficulty, arising from the value of the interests involved, which are sometimes so great that the abolition of such erections cannot be effected without large compensation. The weirs on the Dee in Cheshire, and the Lune in Lancashire, are instances of this, being productive of much injury; while in both cases the interests affected are so important, and the consequences so serious, as hitherto to have operated as an effectual barrier to their removal. The removal of existing quays and other works of long standing, as in the case of the Thames, the Tyne, and the Wear, is also for the same reason difficult, and works must therefore be designed for such localities which shall not injuriously affect existing interests. But all natural weirs or shoals, consisting of fixed rock or hard gravel, which cannot be disturbed by the action of the current, as well as all projections into the stream, where unattended by the difficulties alluded to, should at once be removed. Whenever it is possible, divided currents should be united into one stream. The channel, where it is necessary, should be guided by longitudinal walls, and the river's bed should be deepened to the full extent compatible with a due amount of slope being left on the surface.

These may be said to be the safest and most beneficial works which can be adopted in designing river improvements, their effect being to cause the currents of flood and ebb tide to flow always in one channel, and thus to exert their full and combined power in keeping open one navigable

track. The manner in which they are executed demands a few remarks; and we shall treat the different works under the heads of:—

1. Removal of lateral obstructions.
2. Closing subsidiary channels.
3. Dredging.
4. Excavation.
5. River walls; and
6. Scouring.

1. Removal of Lateral Obstructions.

Under the "Removal of Lateral Obstructions" may be classed all those works which have for their object the formation of proper outlines for the banks or sides of the river. In the early history of river engineering it was not uncommon to construct jetties or groins projecting from the banks on either side, with the view of narrowing the stream and producing a greater scouring power to operate on the bottom. It is no doubt true, that such projections have the effect of producing a *local* acceleration of the currents, and in soft bottoms a corresponding increase of depth in their immediate vicinity. But this increase of velocity and depth being due entirely to the obstruction and consequent raising of the level of the water caused by the jetty, is strictly local. Whenever the water passes the head of the jetty, it expands into the greater width of bed, the head is reduced, a stagnation or eddy takes place, and a bank or shoal is formed,—a result which invariably follows the projection of any obstruction or foreign body into a stream having a soft bottom. As an aggravated instance of the effect of such obstructions, we may refer to the case of a vessel of about 170 tons, which, in consequence of the breaking of a tow-line, grounded at the side of the River Tay when there was some flood in the river. The effect

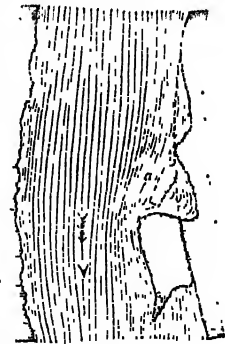

Jetties ob-
jectionable.

Fig. 4.

is shown in fig. 4, where the vessel is represented at *a* as lying in a pool which was scoured to the depth of about 10 feet in the course of a few tides; and the gravel thus excavated by the current, acting on the grounded vessel, and amounting to upwards of 1000 tons, was deposited in the form of a bank, 5 feet above low-water, immediately below the pool, as shown in hatched lines. A similar effect, though varying in degree, occurs in all rivers confined by jetties. The beds of rivers so treated consist of an alternation of shoals nearly dry at low-water, and pools of a depth far greater than is actually requisite, instead of presenting, as they ought to do, a regular bottom and a uniform depth of water available for the purposes of navigation. Examples of the prejudicial effect of jetties are to be met with in the history of the Clyde, the Ribble, the Dee in Cheshire, the Tay, and, the writer believes, with little or no exception, in every situation where the system of contracting, or even directing the currents by means of such works, has been generally adopted. From the Clyde, the Ribble, and the Tay they have been entirely removed. The writer has invariably found, that whenever jetties existed, their entire or partial removal formed one of the first steps towards an improvement of the navigation, and this course has, in all cases which have come within his experience, been followed by good results. In some instances, where the river is contracted by the projection of quays or by the natural formation of the banks, it is desirable, where it can be done consistently with existing interests, to enlarge the cross-sectional area, in order to reduce the velocity of the currents and prevent disturbance of the tidal flow.

2. Closing Subsidiary Channels.

The next work to be noticed is the closing of what we term subsidiary channels. These are channels, or, as they are sometimes called, *back lakes*, caused by islands which divide the stream and reduce its scouring power. The consequence is, that instead of flowing in one broad, deep, navigable bed, kept open by the whole available scouring power, the river is divided into two shallow channels, neither of them affording a good navigation, while frequently a ford or shallow is occasioned both above and below the island by the disturbance which occurs at the junction of the divided currents. On the Tay and the Lune several such secondary channels were, with much advantage to the navigation, closed up by means of embankments formed of gravel dredged from the river, while the other or principal channel was enlarged and deepened, so as fully to compensate for the closing of the smaller channel, and assimilate its cross-sectional area to the rest of the navigable track.

3. Dredging.

The introduction of mechanical appliances for the purpose of excavating materials under water, raising them to the surface, and depositing them in barges, was an important era in canal and river engineering. The first employment of machinery to effect this important object is, like the discovery of the canal lock, claimed alike for Holland and Italy, in both of which countries dredging is believed to have been practised before it was introduced into Britain. The moving power at first employed in conducting the process was manual labour, but in all large works dredging is now performed by steam, and is probably the most effective and generally applicable means of improvement at the command of the engineer. The Dutch, at a very early period, employed what is termed the "bag and spoon" dredge for cleaning their canals. It consisted of a ring of iron about 2 feet in diameter, flattened and steeled for about one-third of its circumference; to this ring a bag of strong leather was attached by means of thongs, and the whole apparatus was fixed to a long pole, which, on being used, was lowered to the bottom from the end of a barge moored in the canal or river. A rope made fast to the iron ring was then wound up by a windlass placed at the other end of the barge, and the spoon was thus dragged along the bottom, and was guided in its progress by a man who held the pole. When the spoon reached the end of the barge where the windlass was placed, the winding was still continued, and it was raised to the surface, bringing with it the stuff excavated, and deposited in the bag during its progress along the bottom. The windlass being still wrought, the whole was raised to the gunwale of the barge, and the bag being emptied, was again lowered and hauled back to the opposite end of the barge for another supply. This system is slow, and only adapted to a limited depth of water and a soft bottom. It has, however, been generally employed in canals, and was much used in the Thames; and the writer, in one situation where, from want of space and other peculiarities, more perfect mechanical means could not be employed, used it to a pretty large extent, the quantity raised being about 135,000 tons. The process, although tedious, was very convenient, and the cost of raising the materials did not exceed 7½d. per ton. Another plan practised at an early period was to moor two large barges, one on either side of the river; be-

tween them was slung an iron bucket or box, attached to both barges by chains wound round the barrels of a powerful crab-winch in one barge, and round a capstan in the other. The bucket was lowered at the side of the barge in which was the capstan, and being drawn across the bottom by the crab in the opposite barge, was raised and emptied; after which it was again lowered, and hauled across by the capstan for a repetition of the process. But in all large operations these and other primitive appliances have, as already stated, been superseded by the steam-dredge, which was first employed, it is believed, in deepening the Wear at Sunderland, about the year 1796. This machine was made for Mr Grimshaw by Bolton and Watt.¹ Receiving improvements from Mr Hughes, Mr Rennie, Mr Jessop, and others, the steam-dredge, as now generally constructed, is a most efficient machine, excavating and raising materials from the depths of 15 to 20 feet of water, at a cost not very different from that at which the same work could be performed on dry land.

For details as to the construction of steam-dredges, we have to refer to the articles in *Weale's Quarterly Papers*, already quoted. As to the nature and extent of work performed by them, we may state generally, that almost all materials, excepting rock or very large boulders, may be dredged with ease. Loose gravel is probably the most favourable material to work in; but a powerful dredge will readily break up and raise indurated beds of gravel, clay, and boulders. In such cases it is usual to alternate on the bucket-frame, a bucket of sheet-iron for raising the stuff, with a rake or pronged instrument for disturbing the bottom. Hand-dredges have been used by Messrs Stevenson at several harbours, by means of which, even disintegrated or rotten rock has been easily raised; and the writer believes, that in very many cases the surfaces of submerged rocks near the mouths of harbours may, by means of such machines, be broken up and removed, so as to obtain in certain situations a considerable increase of depth, without recourse to coffer-dams, which, on exposed coasts, involve great expense and sea risk, as well as interruption to the trade. These small dredges are worked by eight or ten men, and cost about £350.

A well-constructed steam-dredge of 16 horse-power will, under favourable circumstances, raise about 140 tons of stuff per hour. The excavated materials are first discharged into lighters or barges, and then deposited in any convenient position, where they are sufficiently removed from the risk of being carried off by floods, and again thrown into the bed of the river.

In some cases the discharge is made into hopper punts or barges, which are floated out to sea, and the stuff is dropped in deep water. The cost of steam-dredging varies according to the nature of the material and the circumstances of working, as regulated by the tides and the distance of deposit. It has, in the writer's own experience, varied from 4d. to 6d. per ton, or from 5½d. to 8d. per cubic yard, including all expenses.² We believe that in no place has steam-dredging been more extensively used than in the Clyde, where the navigable depth has been increased and is maintained mainly by that process. The following details as to the dredging on that river are given in a communication made to the Institute of France by the late Mr William Bald, who acted as resident engineer on the Clyde.³ Mr Bald says, that annual dredging to the amount of from 160,000 to 180,000 tons was necessary at the time he wrote, in order to maintain the navigable depth of water in the Clyde in the 18 miles from Glasgow seawards. In execut-

¹ *Encyclopædia of Civil Engineering*, by Edward Cresy, London, 1847; "The Dredging Machine," *Weale's Quarterly Papers*, part 1, London, 1843; *The Improvement of the Port of London*, by R. Dodd, Engineer, 1798.

² It was found on the Tay that 18 cubic feet of gravel weighed 1 ton.

³ *Civil Engineers' and Architects' Journal* for August 1846.

Rivers. ing this work, the river trustees employed 5 dredges, a steam-tug, 2 diving-bells, and 160 punts; the whole value of the working machinery being about L.39,000. The following table gives the details of the dredging-machines:—

Rivers.

No. of Dredge.	When she commenced to work.	Greatest depth of Working.	Least depth of Working.	Diameter of Cylinder.	Length of Stroke.	Number of Buckets.	Length of Bucket-frame.	Nominal Power of Engine.
1	1824	Ft. 10 in. 6	Ft. 3 in. 9	Inches. 21	Ft. 2 in. 6	31	Ft. 47 in. 9	12
2	1826	14 0	4 0	24	2 6	33	52 11	16
3	1830	14 0	4 0	24	2 6	33	52 11	16
4	1836	15 6	4 3	26	2 6	34	54 7½	20
5	1841	17 to 19 ft.	4 4	27½	2 6	34	58 0	22

All these dredges had governors, which regulated the speed to about 28 strokes per minute in ordinary working stuff. The average pressure in boilers was about 3½ lb. per square inch. In general, 14 buckets were discharged per minute. The speed of the buckets on the frames of dredges Nos. 1, 2, 3, and 4, was 48 feet 5 inches per minute, and that on No. 5, 49 feet 8 inches per minute. They consumed from 15½ to 18 lb. of coal per horsepower per hour. The following is a statement of the

amount of work which was performed by these dredges, and the expense of the process:—

Year ending	Amount expended.	Work executed.	Rate per Cubic Yard.
December 25, 1841....	L. 11,841 s. 18 d. 2	218,110	L. 0 s. 1 d. 1
... 24, 1842....	13,612 11 3	313,810	0 0 10½
... 23, 1843....	9,742 7 6½	294,440	0 0 8
... 21, 1844....	10,659 3 8	317,660	0 0 8

Tabular View of the Dredging of the Wear at Sunderland in 1842-46.

Date.	Total Quantity Raised per Annum.	Expenditure in Labour for Raising and Depositing per Annum.	Expense of Fuel per Annum.	Expenditure in Labour for Repairs per Annum.	Expenditure in Materials for Repairs per Annum.	Total Expenditure per Annum.	Average cost per Ton on the Year's Expenditure.

1842 to 1846	Hence the average cost per ton on five years' work—						
	For raising and depositing at sea						= 1.628
	For fuel						= 0.149
	For labour in repairs						= 0.943
	For materials to ditto						= 1.243
	Average total Expenditure.....						= 3.863

Mr Murray gives the above tabular view of the dredging of the Wear at Sunderland, which is also an interesting record of the quantity and cost of material raised by a dredging-machine; but this view is not given by way of comparison with the preceding, as there is little analogy between the cases. The contracted state of the Clyde, the frequent interruptions to which the work was subject by the constant passage of vessels, and the expense of removing and depositing the stuff, necessarily increased the cost of executing the work in that situation.

In river-dredging two systems are pursued; one plan consists in excavating a series of longitudinal furrows parallel to the axis of the stream, the other in dredging cross furrows from side to side of the river. It is found that inequalities are left between the longitudinal furrows, when that system is practised, which do not occur to the same extent in side or *cross-dredging*; and the writer has invariably found cross-dredging to leave the most uniform bottom. To explain the difference between the two systems of dredging, it may be stated, that in either case the dredge is moored from the head and stern by chains about 250 fathoms in length. These chains in improved dredges are wound round windlasses worked by the engine, so that the vessel can be moved ahead or astern, by simply throwing them into or out of gear. In longitudinal dredging, the vessel is worked forward by the head chain, while the buckets are at the same time performing the excavation; so that a longitudinal trench is made in the bottom of the river. When the dredge has proceeded a certain length, it is stopped and permitted to drop down and commence a new longitudinal furrow parallel to the former one. In cross-dredging, on the other hand, the vessel is supplied with two additional moorings, one at either side, and these

chains are, like the head and stern chains, wound round barrels wrought by the engine. In commencing to work by cross-dredging, we may suppose the vessel to be at one side of the channel to be excavated. The bucket-frame is set in motion, but instead of the dredge being drawn forward by the head chain, she is drawn to the opposite side of the river by the side chain, and having reached the extent of her work in that direction, she is then drawn a few feet forward by the head chain; and the bucket-frame being yet in motion, the vessel is hauled back again by the opposite side chains to the side from whence she started. By means of this transverse motion of the dredge, a series of cross furrows is made; she takes out the whole excavation from side to side as she goes on, and leaves no protuberances such as are found to exist between the furrows of longitudinal dredging, even where it is executed with great care. The two systems will be best explained by reference to the annexed cut (fig. 5), where AB repre-

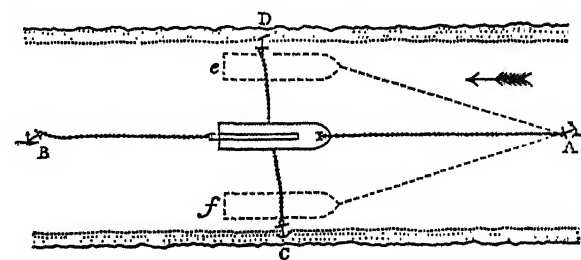

Fig. 5.

sents the head and stern moorings, and DC the side moorings; the arc of represents the course of the vessel in cross-dredging; while in longitudinal dredging, as already ex-

cross-dredging.

Rivers.

plained, she is drawn forward towards A, and again dropped down to commence a new longitudinal furrow.

In some cases, however, the bottom is found to be too hard to be dredged until it has been to some extent loosened and broken up. Thus at Newry, Mr Rennie, after blasting the bottom in a depth of from 6 to 8 feet at low-water, then removed the material by dredging, at an expense of from 4s. to 5s. per cubic yard. The same process was adopted by Messrs Stevenson at the bar of the Erne at Ballyshannon, where, in a situation exposed to a heavy sea, large quantities of boulder stones were blasted, and afterwards raised by a dredger worked by hand, at a cost of about 10s. 6d. per cubic yard. But the most extensive application of blasting, preparatory to dredging, of which the writer is aware, was that on the works for improving the Severn, by Sir William Cubitt, of which an interesting and instructive account is given by Mr George Edwards, in a paper addressed to the Institution of Civil Engineers, from which the following particulars are taken:¹—

"It appears that a succession of marl beds, varying from 100 yards to half a mile in length, were found in the channel of the Severn, which proved too hard for being dredged, the whole quantity that could be raised being only 50 or 60 tons per day; while the machinery of the dredges employed was constantly giving way. Attempts were first made to drive iron rods into the marl bed, and to break it up; a second attempt was made to loosen it by dragging across its surface an instrument like a strong plough. But these plans proving unsuccessful, it was determined to blast the whole surface to be operated on. The marl was very dense, its weight being 146 lb. per cubic foot;² and it was determined to drill perpendicular bores, 6 feet apart, to the depth of 2 feet below the level of the bottom to be dredged out. The bores were made in the following manner, from floating rafts moored in the river:—Pipes of $\frac{3}{8}$ -inch wrought-iron, $3\frac{1}{2}$ inches diameter, were driven a few inches into the marl. Through these pipes holes were bored, first with a $1\frac{1}{2}$ -inch jumper, and then with an auger. The holes were bored 2 feet below the proposed bottom of the dredging, as it was expected that each shot would dislocate or break in pieces a mass of marl of a conical form, of which the bore-hole would be the centre and its bottom the apex; so that the adjoining shots would leave between them a pyramidal piece of marl, where the powder would have produced little or no effect. By carrying the shot-holes lower than the intended dredging, the apex only of this pyramid was left to be removed; and in practice this was found to form but a small impediment. Fig. 6 is a section, and

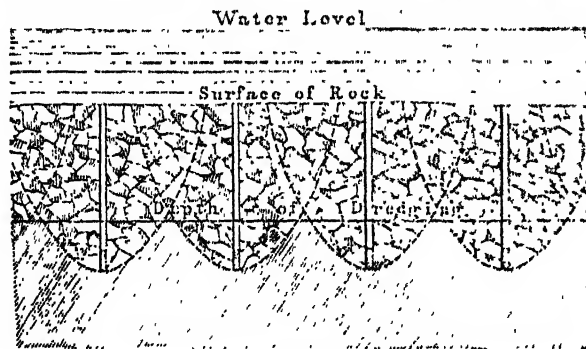

Fig. 6.

fig. 7 a plan of the bore-holes; the inner dotted circles represent the diameters of the broken spaces at the level of the bottom of dredging. The cartridges were formed

in the ordinary way, with canvas, and fired with Pickford's fuse. The weight of powder used for bore-holes of 4 feet, 4 feet 6 inches, and 5 feet, were respectively 2 lb., 3 lb., and 4 lb. The effect of the shot was generally to lift the pipes a few

Rivers.

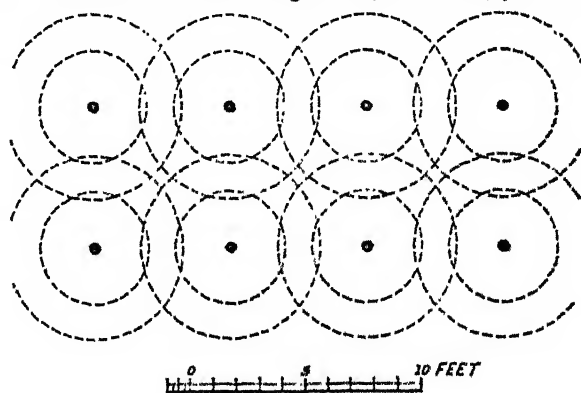

Fig. 7.

inches, which were secured by ropes to the rafts. Mr Edwards says that not one in a hundred shots missed fire, and these shots were generally saved by the following singular expedient:—The pointed end of an iron bar, $\frac{1}{4}$ -inch diameter, was made red-hot, and being put quickly through the water, and driven through the tamping as rapidly as possible, was in nine cases out of ten sufficiently hot to ignite the gunpowder and fire the shot.

"The cost of each shot is calculated as follows:—

Use of material.....	£0	1	0
Labour.....	0	3	3
Pitched bag for charge.....	0	0	3
3 lb. of powder at 5½d.....	0	1	4½
15 feet of patent fuse at ½d this of a penny.....	0	0	9
Pitch, tallow, twine, coals, &c.....	0	0	4½

Cost per shot£0 7 0

Each shot loosened and prepared for dredging about 4 cubic yards; so that the cost for blasting was 1s. 9d. per yard. The cost of dredging the material, after it had been thus prepared, was 2s. 3d.; making the whole charge for removing the marl 4s. per cubic yard."

4. Excavation.

But there are cases where the bottom cannot be advantageously operated on by any of the means we have mentioned, and where it is necessary to have recourse to other appliances for its removal, such as the diving-bell or diving-helmet, and coffer-dams. The diving-bell has, in conjunction with dredging, been much used on the Clyde, and Mr Bald gives the following account of the operation as conducted on that river:—

"Between Erskine Ferry and the New Shot Isle the bed of the Clyde, for a distance of 2000 yards, was greatly encumbered with stones and stone boulders, which were highly injurious to vessels if they grounded there; and frequently large ships, in being tugged through this part of the river-channel, had their copper bottoms injured when they touched the rocky channel-bed. In deepening and clearing this part of the river, two diving-bells were employed, and one, and sometimes two, steam-dredgers. The clearing and deepening of this channel was exceedingly severe on the machinery and working-gear of the steam-dredgers; the speed of the engines was therefore governed by the nature of the material in the bottom; and although the iron-work frequently gave way, yet spare links and buckets being always ready to replace those

¹ "Account of Blasting on the Severn," by George Edwards, C.E. (*Trans. of Institution of Civil Engineers*, vol. iv., p. 361).

² Clay weighs about 109 lb., and sandstone about 155 lb. per cubic foot.

Rivers. which broke, there was little interruption to the continuous working of the dredgers. When the dredgers had cleared away the material which covered the boulders in the bottom of the channel, the diving-bell boats were worked over the ground so cleared, removing all the larger boulders; and when that part of the channel had been cleared of them, the dredgers went again over the same bottom, removing all the lighter material from the heads of the lower boulders, preparatory to the bells commencing again; and these operations were continued until the necessary depth was attained.

"The buckets of the steam-dredgers, in working along the bottom, always slipped over the head of the large boulders, which the diving-bells alone could lift and remove. Some of these masses of trap or whinstone were 4 and 5 tons in weight, and from their rounded forms and smooth surfaces, it was evident that they had been brought from some distance. Some of them were of sandstone, but they were more angular than the trap boulders. Quantities of these boulders, lifted from the bed of the channel, might be seen lying along the sides of the river; and many of them had since been split and broken up by gunpowder for repairing the river dykes. The tops of some of the large stone boulders lifted from the bed of the channel were found grooved to a depth of about an inch or more, by the ship's keels having been rubbing over them; and metallic particles were distinctly to be seen upon their surface. In removing these stone boulders from the bed of the channel, the diving-bell men found numerous fragments of copper and iron which had been torn off the ship's bottoms and keels by the large stones; but latterly this had not been the case, as great progress had been made in the removal of the boulders, and the deepening of the channel."

Large isolated masses of stone have also been removed *en masse* from many rivers by fixing lousies in them, and raising them by floatation. On the Tay this was done to some extent, and one boulder of 50 tons was raised from the river by that means. Where a large area and considerable depth of solid rock has to be removed, coffer-dams are doubtless the best means of executing the work; but the chief difficulty in employing dams in the narrow channels of rivers is the obstruction which they necessarily present to the passage of floods and also to shipping. It is therefore a matter of high importance to reduce their bulk to the smallest possible limits. With this view the writer¹ By coffer-dams, designed a coffer-dam for the works of the River Ribble, which consisted of two rows of iron rods, 3 feet apart, jumped into the rocky bottom, and supporting two linings of planking, the intermediate space being filled with clay, and the whole structure being stayed from the inside, so as to present no obstruction beyond the outer line of the dam. Three dams of this construction were formed in the Ribble; and by means of them, a bed of rock, 300 yards in length, and of a maximum depth of 13 feet 6 inches, was successfully excavated. The maximum depth of water at high-water against the dam was 16 feet, but in very high floods of the river the whole dam was sometimes completely submerged; but on the water subsiding, it was found that the iron rods, on which alone its stability depended, although only jumped 15 inches into the rock, were not drawn from their fixtures. As this construction of dam completely overcomes the difficulty of fixtures in a hard bottom, where piles cannot be driven, and offers very little obstruction to the navigation; and moreover, as it has been successfully used on a large scale, and seems to fulfil all the conditions demanded in such a situation, it may be perhaps considered generally applicable to situations where

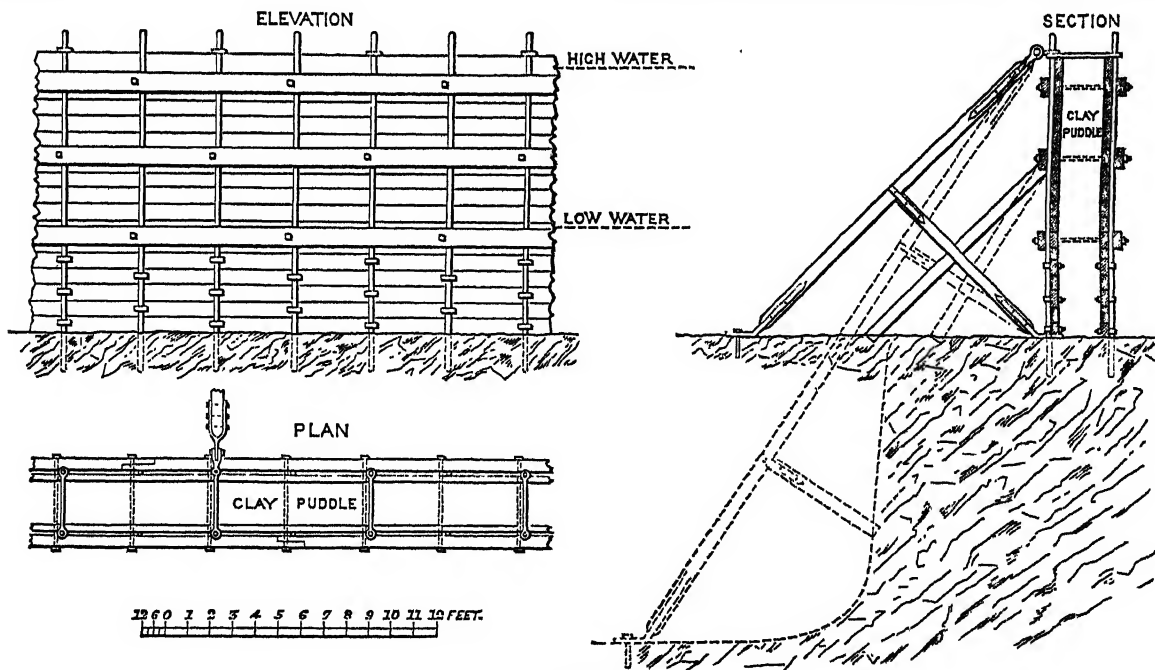

Fig. 8.

there is a hard bottom and limited space. The sketch (fig. 8) shows, by an elevation, section, and plan, the manner in which it was constructed.

5. River-Walls.

In open estuaries filled with sand-banks, the courses of

rivers are liable to constant alteration, due to every change in the tides or winds. The accompanying woodcut (fig. 9) of the River Lune illustrates this remark; the several dotted lines represent the variation of the channel during the period of a few years. This tendency to wander is common to all rivers when left undirected to work their way through a

¹ "Description of a Cofferdam adapted to a Hard Bottom," by David Stevenson, C.E. (*Trans. of Inst. of Civil Engineers*, vol. iii., p. 377).

Rivers.

tract of sand; and the evils attending such a state of matters are generally of a serious nature, proceeding mainly from a constant abrasion or wasting of the sand-banks. This

abrading action, operating during every flood and ebb tide, sets loose a large amount of floating sand, which is drifted to and fro, and deposited in some new situation. A channel

Rivers.

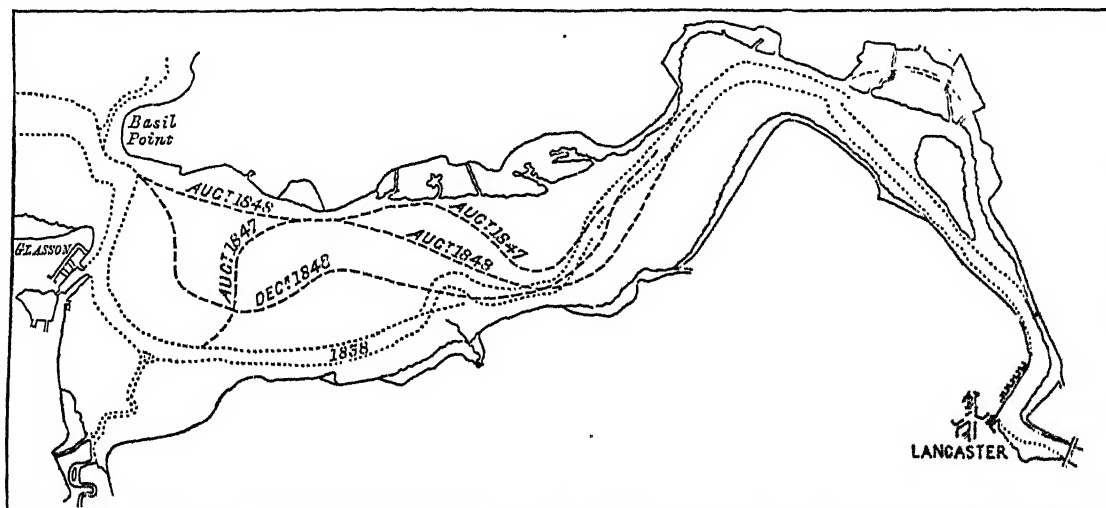

Fig. 9.

which is constantly shifting its course never remains sufficiently long in one position to form for itself a properly defined bed, but is in fact always in a transition state; the sand which is worn from the *concave* being thrown to the *convex* side of the stream, while some portion of the floating materials, carried to and fro during this process of perpetual change, is often deposited, and forms shoals in the middle of the fairway. A river left in this state of nature cannot possibly attain the *maximum* depth due to the natural scour of the tidal currents, as their power is expended in abrading and removing the sand-banks through which the stream flows, and not, as it ought to be, in deepening and scouring its bed. In such cases what is wanted is to secure a permanent channel, by guiding the first of the flood and the last of the ebb tide by means of walls, so that the strength of the currents may constantly operate on the *same line of channel*. In this way, it is obvious that not only will the advantage of a permanent navigable track be obtained, but the constant action of the currents of flood and ebb tide flowing in the same channel, will secure a much greater permanent depth than they could possibly do if permitted to wander at random through the estuary, sometimes operating in the same channel, and at other times directly opposed to each other.

shown in fig. 10, in which the axis of the stream is represented by the dotted line. Dr Young observes that the centrifugal force in curved channels has a tendency to draw the greater portion of the water to the concave side, and thus the greatest scouring power, and consequently the greatest depth of the stream, will be found upon that side. In a channel directed by straight walls (fig. 11), the current has no such decided bias for either wall, and is consequently easily thrown across from side to side. A wall, on the other hand, having a convex outline, as shown in fig. 12, is (especially if the radius of curvature be small) still less suitable as a guide, as the line of wall diverges from the direction of the axis of the current. These remarks are not hypothetical, as the writer has found that their correctness has been verified by cases in actual practice. There is doubtless some disadvantage in the deep water being on one side of the channel, as more particularly shown in the cross section, fig. 13. It would be more convenient for naviga-

Comparative advantages of straight and curved walls.

Questions have been raised as to the comparative advantages of straight and curved walls for directing a channel. It is believed that, in most cases, the direction of such walls is necessarily determined, not by any abstract consideration as to the superiority of straight or curved walls, but chiefly by the relative positions of the points between which the stream is to be conducted, and the outline and geological formation of the shores and banks of the estuary that intervene between those points. The consideration of such matters may render it expedient, according to the special circumstances of the locality, to adopt walls having *concave*, *straight*, or *convex* outlines, as shown in figs. 10, 11, and 12.

Viewed as a purely abstract question, it may, we think, be safely affirmed, that a stream is most likely to follow a permanent course when directed by a concave wall, as

tion were the deep water in the centre; but it is found that the current invariably adheres to one or other of the walls, and it is better that the channel should keep constantly to one wall, than that it should alternate from side to side, as is more apt to be the case in absolutely straight channels.

The direction and extent of river-walls must, however, be carefully considered by the engineer with reference to existing circumstances, and every case must be judged *per se*. But we think it will be found safe, in executing such works, to adhere as closely as possible to the following general rules:—

First, The channel through open estuaries should, in all cases where funds will admit of it, be guided by double walls. In cases, however, where the estuary is bounded by a hard beach, presenting a favourable line of direction, a single wall may occasionally be found sufficient. All curves which it may be necessary to introduce should be of as large a radius as possible, and should, if practicable, be tangential to each other, or to the straight parts of the line with which they are connected.

Second, The walls should not be raised to a higher level above the low-water line than is absolutely necessary for the purpose of conducting the early and late currents of the

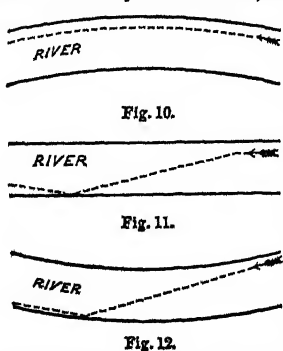

Fig. 13.

Rivers. tide; and their direction should be marked by occasional perches.

Fig. 14 represents the disposition of such walls in estu-

aries, as executed under the direction of Messrs Stevenson. They are raised from 3 to 5 feet above the low-water line so that, while they guide the low-water channel, they do

Rivers.

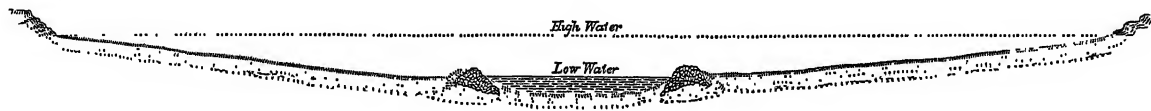

Fig. 14.

not prevent the tide at high-water from flowing on either side of them and filling the estuary.

Third, River-walls should, during their erection, be pushed forward with vigour, and not in a desultory, timid manner; the effect of such a course being to increase the depth of water in which the wall has to be made, and the amount of stone required for its construction.

Fourth, It will be found that such walls as we have been describing will be most advantageously formed of rough rubble stones, backed with clay and gravel, in the manner shown in fig. 15.

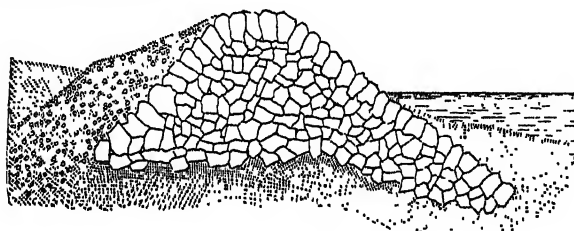

Fig. 15.

It was found by Mr Park, under whose immediate directions, as local engineer, the walls on the River Ribble, which are about 12 miles in length, were constructed, that their foundations, with few exceptions, did not sink more than a few feet below the sand. He found that it was advantageous to mix clay in the internal core of the wall; and after the materials were deposited, it was necessary from time to time, in certain places, to add additional stones to make up slips, before attempting to pitch the top or the face of the slope. Walls somewhat similar have also been largely introduced on the Clyde by Mr Walker.

6. Scouring.

The removal of hard portions of the bed of a river by dredging or coffer-dams, and the direction of the channel by low walls, are operations which are in themselves improvements; but they further operate beneficially in causing the currents to scour the softer parts of the river's bed, so that it sometimes happens that by dredging a few hundred yards of hard material from a river's bed, or erecting a short wall, thousands of tons of soft materials are scoured away by the action of the current. In all river improvements this is an effect which should be fully taken into consideration by the engineer, especially in forming estimates; and its importance will be apparent on inspecting the section of the River Lune (Plate II.) By dredging the upper shoals of that river, which are marked in hatched lines in the section, the whole lower part of the river was deepened by the natural scour, without entailing any expense in its removal. To facilitate this scour, a species of harrow has sometimes been applied,

which is drawn to and fro by a tug-steamer across the bank to be removed. This system was extensively employed by Captain Denham in opening the Victoria Channel at the Mersey; it was also employed by Messrs Stevenson at the Tay; but it is obvious that it can only be advantageously used where there is deep water in the immediate neighbourhood of the bank to be removed, in which the sand and mud disturbed by the harrow, and carried off by the current, may be deposited. The process of scouring has, in some situations, to the knowledge of the writer, continued in operation for many years after the completion of the original work, the low-water level of the river continuing gradually to sink; and as this process goes on, it sometimes happens that hard portions of the bottom originally covered become gradually exposed.¹ Such obstructions are, in fact, hard portions of the bed brought to light, in consequence of the improvement of the river, and must not be mistaken for accumulations due to ill-regulated currents. It is necessary, however, that such hard portions should be removed as soon as they appear, otherwise they disturb the currents and occasion shoals. Whenever the depth due to the currents acting in their improved direction has been reached, such obstructions will cease to present themselves.²

The effect of works executed according to the principles indicated is,—*First*, to fix the navigable track in a defined course; *second*, to deepen the bed of the river; *third*, to reduce the slope, and lower the low-water level; and, *fourth*, to increase the duration of tidal influence and the quantity of tidal water in the river. The benefits to navigation are threefold:—*First*, greater depth of water; *second*, a properly defined channel; and, *third*, a greater length of time during which, in consequence of the presence of the tide, the river is navigable.

The writer has, before leaving this part of the subject, to state that the works specified are believed to be those most generally applicable. All of them may not be applicable in every case; and there may be special cases which render it expedient to adopt works of a somewhat different, and, in some respects, apparently antagonistic character,—such, for example, as the contraction of channels by means of quay-walls.

SECT. V.—APPLICATION OF THESE WORKS IN PRACTICE.

We come now to give a sketch of navigation improvements, executed in accordance with these general views, and to show their application in practice, and the effect produced by them. The first example to which we shall allude is the River Tay, improved under the advice and direction of Messrs Stevenson of Edinburgh; as we know of no instance in which the improvements effected by particular works are more fully and satisfactorily demonstrated by a comparison

Application of these works in practice.

¹ Mr Rendel, in his address as president of the Institution of Civil Engineers in 1852, says,—“At the present moment changes are taking place in the Thames and most of the principal rivers, which afford invaluable opportunity for observations on the effects rivers can produce by their own action, and also on what is done by the passage of steam-vessels in keeping the lighter silt constantly in motion.”

² Admiral Beechey, in his *Observations on the Tides of the River Severn*, mentions a fact which it is proper to record. He says, “While upon the subject of the low-water line, it may here be remarked, that the inverse of the ordinary effect of the spring-tide occurs in the river above Lidney. From Lidney downwards to the sea, the low-water at springs follows the general rule of being lower at such times than at the neaps; but above Lidney the reverse takes place, the low-water at the springs being higher than at the neaps. This, no doubt, is occasioned by the tide at springs throwing more water into the river than can escape before the return of the following tide.”

Rivers. of observations made *previously* and *subsequently* to their execution, than in the case of that navigation; where the changes were brought about in so short a time, and were so marked as to leave no doubt, even to superficial observers, of their attainment, and no difficulty, by the use of proper means, in ascertaining their amount.

River Tay. The River Tay, with its numerous tributaries, as stated in the table at the end of this treatise, receives the drainage-water of a district of Scotland amounting to 2283 square miles, as measured on Arrowsmith's Map. Its *mean* discharge has been ascertained to be 274,000 cubic feet, or 764½ tons of water per minute. It is navigable as far as Perth, which is 22 miles from Dundee, and 32 from the German Ocean. The different points on the river, hereafter to be referred to, will be seen in the small chart given in Plate II.; and we propose, in this particular case, to enter somewhat into detail as to the nature of the obstructions to the navigation, the means employed for their removal, and the effects produced by the works on the tidal currents; as the remarks made will, it is believed, serve to illustrate the subject of river improvement generally.

Before the commencement of the works, certain ridges, called "fords," stretched across the bed of the river at different points between Perth and Newburgh, and obstructed the passage to such a degree, that vessels drawing from 10 to 11 feet could not, during the highest tides, make their way up to Perth without great difficulty. The depth of water on these fords, the most objectionable of which were six in number, varied from 1 foot 9 inches to 2 feet 6 inches at low, and 11 feet 9 inches to 14 feet at high water of spring tides; so that the regulating navigable depth, under the most favourable circumstances, could not be reckoned at more than 11 feet. In addition to the shallowness of the water, many detached boulder stones lay scattered over the bottom. Numerous "fishing cairns," or collections of stones and gravel, had also been laid down, without regard to any object but the special one in which the salmon-fishers were interested, and in many cases they formed very prominent and dangerous obstructions to vessels. The chief disadvantages experienced by vessels in the unimproved state of the river was the risk of their being detained by grounding, or being otherwise obstructed at these defective places, so as to lose the tide at Perth,—a misfortune which, at times when the tides were falling from springs to neaps, often led to the necessity either of lightening the vessel, or of detaining her till the succeeding springs afforded sufficient depth for passing the fords. The great object aimed at, therefore, was to remove every cause of detention, and facilitate the propagation of the tidal wave in the upper part of the river, so that inward-bound vessels might take the first of the flood to enable them to reach Perth in one tide. Nor was it, indeed, less important to remove every obstacle that might prevent outward-bound vessels from reaching Newburgh, and the more open and deep parts of the navigation, before low-water of the tide with which they left Perth.

The works undertaken by the harbour commissioners of Perth for the purpose of remedying the evils alluded to, and which extended over six working seasons, may be briefly described as follows:—

1st. The fords, and many intermediate shallows, were deepened by steam-dredging; and the system of harrowing was employed in some of the softer banks in the lower part of the river. The large detached boulders and "fishing cairns," which obstructed the passage of vessels, were also removed.

2d. Three subsidiary channels, or offshoots from the main stream, at Sleepless, Darry, and Balhepburn islands, the positions of which will be seen on the plan, were shut up by embankments formed of the produce of the dredging, so as to confine the whole of the water to the navigable channel.

3d. In some places the banks on either side of the river beyond low-water mark, where much contracted, were excavated, in order to equalize the currents, by allowing sufficient space for the free passage of the water; and this was more especially done on the shores opposite Sleepless and Darry islands, where the shutting up of the secondary channels rendered it more necessary.

The benefit to the navigation in consequence of the completion of these works has been of a twofold kind; for not only has the depth of water been materially increased by actual deepening of the water-way, and the removal of numerous obstructions from the bed of the river, but a clearer and freer passage has been made for the flow of the tide, which now begins to rise at Perth much sooner than before; and as the time of high-water is unaltered, the advantages of increased depth due to the presence of the tide is proportionally increased throughout the whole range of the navigation; or, in other words, the duration of tidal influence has been prolonged.

The depths at the shallowest places are now pretty nearly equalized, being 5 feet at low and 15 feet at high water, of ordinary spring tides, instead, as formerly, of 1 foot 9 inches at low and 11 feet at high water. Steamers of small draught of water can now therefore ply at *low-water*, and vessels drawing 14 feet can now come up to Perth in *one tide* with ease and safety.

In obtaining the requisite data, both as to the design and execution of these works, minute tidal observations were made at various times during a period of ten years, from 1833 to 1844 inclusive, throughout the River and Firth of Tay, at the following stations,—viz., Dundee, which is marked No. 1 on the plan, Plate II.; Balmerino, No. 2; Flisk Point, No. 3; Balmreich Castle, No. 4; Newburgh, No. 5; Carpow, No. 6; Kinfauns, No. 7; and Perth tide harbour, No. 8. The general results deduced from these observations are given in the following tables, and show, by the favourable change which has been effected in the tidal phenomena of the estuary, that the works executed fully answered the intended end:—

1. Propagation of Tidal Wave.

The following table of elapsed times, between arrival of the tide-wave, or commencement of the tidal flow, at the following stations, during *spring* tides in 1833 and 1834, shows the rate of its propagation:—

	Time. h. m.	Distance in Miles.	Rate of Tide- Wave in Miles per Hour.
Dundee to Balmerino.....	0 16	5.00	18.75
Balmerino to Flisk Point.....	0 29	2.93	6.06
Flisk Point to Balmreich.....	0 26	2.64	4.69
Balmreich to Newburgh.....	0 53	3.42	3.86
Newburgh to Perth (tide harbour).....	2 30	8.56	3.42

The result of observations made in 1842, 1843, and 1844, on spring tides, give the same velocity, as above stated, between Dundee and Newburgh, and the following rates between Newburgh and Perth:—

	Time. h. m.	Distance in Miles.	Rate of Tide- Wave in Miles per Hour.
Newburgh to Carpow.....	0 25	1.33	3.17
Carpow to Kinfauns.....	0 55	4.92	5.36
Kinfauns to Perth (tide har.)..	0 20	2.32	6.93
Giving, as a mean for the whole distance from New- burgh to Perth in 1844...	1 40	8.56	5.13
Time from Newburgh to Perth in 1833.....	2 30	8.56	3.42

Thus showing an increase in the velocity of the tide-wave in the upper part of the river, which was improved, of more than 1½ mile per hour as the result of the improvements.

The difference of the time in *neap* tides between Newburgh and Perth in 1844, was 1 h. 53 m.

Rivers.

Rivers.

2. High-Water Level.

The levels of the surface of high-water at different stations throughout the river have been found to be unchanged, and the following results refer to the years 1833 and 1844:—

From Flisk Point to Balmbreich there is a fall of	5 in.	} Spring Tides.
... Balmbreich to Newburgh there is a rise of	7½ "	
... Newburgh to Perth (tide harbour) there is a rise of.....	18 "	
From Flisk to Balmbreich there is a fall of....	2½ "	} Neap Tides.
... Balmbreich to Newburgh there is a rise of	6 "	
... Newburgh to Perth (tide harbour) there is a rise of.....	12 "	

3. Low-Water Level.

Rise on the Surface of Low-water (Spring Tides) in 1833.

	Ft. in.	Distance in Miles.	Rate of Slope per Mile in Inches.	Rate of Tide in Miles per Hour.
Flisk to Balmbreich there was a rise of.....	0 4	2.04	1.95	4.69
Balmbreich to Newburgh, a rise of	2 8	3.42	9.35	3.86
Newburgh to Perth (tide harbour), a rise of	4 0	8.56	5.06	3.42

Rise on the Low-water of Spring Tides in 1844.

Newburgh to Carpow, there is a rise of.....	0 5	1.33	3.75	3.17
Carpow to Perth there is a rise of.....	1 7	7.23	2.63	...
Hence from Newburgh to Perth, 1844, the rise is..	2 0	8.56	2.80	5.13

The result of the observations of 1844 thus gives a depression on the level of the low-water mark on the gauge of two feet at Perth tide harbour.

4. Duration of Flood and Ebb.

The results of observations in 1833 and 1844 at Newburgh show that the duration of flood and ebb tides at that place are unchanged. The times are as follows:—

Spring Tides flow.....	H. M.
... ebb.....	4 20
Neap Tides flow.....	7 20
... ebb.....	4 30
... ebb.....	6 45

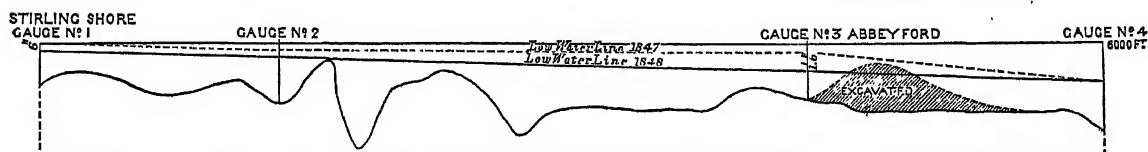

Fig. 13.

passage of vessels. The works were commenced at the lower end of the Abbey ford, and were carried regularly upwards. The new channel excavated through this ford was about 500 yards in length and 75 feet in breadth, and was deepened in some places about 3 feet 6 inches.

Previous to the commencement of the work, tide-gauges were erected in the positions marked 1, 2, 3, and 4, in fig. 16, on which a series of observations was made for the purpose of establishing the original tidal phenomena of the river. After the Abbey ford was cut through, farther observations were made on the same gauges; and it is to a comparison of these two sets of observations that we desire specially to refer. It is necessary to explain that gauge No. 1 is at Stirling quay, No. 2 about 500 yards farther down, No. 3 at the top of the Abbey ford, and No. 4 immediately below it. It will therefore be understood that the Abbey ford, through which a channel was cut, lies between gauges Nos. 3 and 4. The whole of the gauges were placed on the same level, so that their readings might

At Perth in 1833:—

Spring Tides flowed.....	2 20
... ebb.....	7 0
Neap Tides flowed.....	3 15
... ebb.....	7 0

At Perth in 1844:—

Spring Tides flowed.....	3 10
... ebb.....	7 0
Neap Tides flowed.....	3 10
... ebb.....	7 0
Increase of duration of Flood in springs at Perth	0 50

It will be observed from these tables that important changes have taken place:—

First, The fall on the surface of the river from the tide basin at Perth to Newburgh in the year 1833 was 4 feet, but after the works were executed it was only 2 feet.

Second, In 1833 the passage of the tidal wave from Newburgh to Perth (8.56 miles) occupied 2 hours 30 minutes, being at the rate of 3.42 miles per hour; but it is now propagated between the same places in 1 hour 40 minutes, being at the rate of 5.13 miles per hour,—giving a decrease in the time of 50 minutes, and an increase in the speed of the first wave of flood of more than 1½ mile per hour, since the commencement of the works.

Third, The spring tides in 1833 at Perth flowed 2 hours 20 minutes, and ebb 7 hours; but now the tide flows 3 hours 10 minutes, and ebbs 7 hours,—being an increase in the duration of flood of 50 minutes.

The works on the Forth, also executed under the direction of Messrs Stevenson, produced changes on the tidal phenomena, which, in connection with those described on the Tay, are interesting and instructive as regards the propagation of the tide, and therefore we shall briefly allude to them. The river between Stirling and Alloa is very circuitous, the distance by the navigation being 10½ miles, while in the direct line it measures only 5 miles. The navigation was found to be impeded by seven fords or shallows which occur between Alloa and Stirling, and are composed of boulder stones, varying from a few pounds to several tons in weight, embedded in clay.

It was determined, in the first instance, to remove two of these obstructions, viz., the "Town" and the "Abbey" fords, which lie nearest to Stirling, and having the smallest depth of water, form the greatest obstruction to the free

be more easily compared; and the following are the results obtained with reference to the level of the low-water line:—

Levels of Low-water Line.	Gauge No. 4.	Gauge No. 3.	Gauge No. 2.	Gauge No. 1.
In 1847 the low-water line was found to stand at the following levels.....	Ft. in.	Ft. in.	Ft. in.	Ft. in.
In 1840.....	2 0	5 0	5 3	5 6
Depression.....	2 0	3 6	4 6	5 0
	0 0	1 6	0 9	0 6

From this tabular statement, we find that the low-water level at No. 4, which is below the site of the works, remains unaltered, but that it has fallen 1 foot 6 in. at the top of the Abbey ford (through which the cut has been made). It further appears that the formation of this cut has drained off the water, and lowered the surface 9 inches at gauge No. 2, and 6 inches at gauge No. 1, which is at Stirling. The

Rivers.

Rivers. former and present low-water lines and bed of the river are represented in fig. 16, in which is also shown the amount of excavation on the Abbey Ford by hatched lines. This general depression of the level has of course altered the slopes or inclinations formed by the surface of low-water; the slope between 4 and 3 being decreased, while the inclinations between 3 and 2, and between 2 and 1, have been increased in the following ratios:—

Inclinations.	Dist.	1847.	1848.	Difference in 1848.
	Feet.	Inches per Mile.	Inches per Mile.	
Inclination between 4 and 3.....	1550	122.5	61.3	-61.2
Do. do. 3 and 2.....	3050	5.19	20.77	+15.58
Do. do. 2 and 1.....	1400	11.31	22.62	+11.31

Again, these changes on the low-water line have produced corresponding alterations on the velocities of the first wave of flood, which are found to be as follows:—

Velocities.	1847.	1848.	Difference.
	Minutes.	Minutes.	
Time occupied by first wave of tide in passing between gauges Nos. 4 and 3	24	8	-16
Do. do. Nos. 3 and 2...	6	11½	+ 5½
Do. do. Nos. 2 and 1...	6	8½	+ 2½
Do. do. Nos. 4 and 1...	36	28	- 8

From this it appears that between Nos. 4 and 3 there is an acceleration of 16 minutes, while between 3 and 1 there is a retardation of 8 minutes, leaving the difference, or 8 minutes, as the actual amount of acceleration at Stirling, due to the removal of the ford and the lowering of the low-water level 6 inches at that place. The rates of propagation in miles per hour are as follows:—

Rates of Propagation.	1847.	1848.	Difference.
	Miles per hour.	Miles per hour.	
Rates of propagation between Nos. 4 and 3.....	.65	2.2	+1.55
Do. do. Nos. 3 and 2...	5.77	3.0	-2.77
Do. do. Nos. 2 and 1...	2.65	1.87	-0.78

Relations of the slopes and rates of tidal propagation.

These observations and results seem to throw some additional light on the circumstances which modify the propagation of the tidal wave. The table of the results obtained at the Tay shows that the decreased inclination of the low-water lines of that river was attended by an *acceleration* of the velocity of the tidal wave; and the above observations further show that a *retardation* has attended an increased inclination of the low-water line of the upper part of the Forth. From the foregoing tabular statements, it will be seen that between gauges 4 and 3, where the slope has been decreased, the propagation has been accelerated; while between 3 and 2, where, from the state of the works when the observations were made, it is found to have been increased, the rate of propagation had been sensibly retarded. It is worthy of remark, however, that the rates of propagation do not, either at the Tay or Forth, *bear any constant relation to the slopes*, but are modified by other circumstances; in proof of which, it will be found that the rate of propagation at the Forth between gauges 4 and 3, where the slope is 61.3 inches per mile, is actually greater than between gauges 2 and 1, where it is only 22.62 inches per mile. The circumstances of the Forth at this particular place are somewhat peculiar. Before the Abbey ford was cut through, it acted as a dam extending across the river, and had the

effect of increasing the depth at low-water all the way up to Stirling. By cutting the channel through the ford, however, not only has the water been drained off and rendered shallow, but its surface has been broken by the projection of boulders from the bottom, which formerly were entirely covered; and while this effect has taken place in the upper part of the river, a comparatively smooth cut, with regular sides and bottom, has been formed in the Abbey ford, through which the river flows at low-water in a body of considerable depth. The writer therefore attributes the slow propagation of the tide between 2 and 1 to the shallowness of the water and the very rugged state of the bottom, which is in many places completely studded with boulders, rising some above the surface at low-water, and others to within a few inches of it; while the high velocity up the steep slope of the ford is to be attributed—1st, To the depth of water caused by the whole river being made to pass through a comparatively narrow channel; 2d, To the rectangular cross section of the cut; and 3d, To the smoothness of the sides and bottom. At the Firth of Dornoch, again, as already noticed, between the Quarry and Bonar Bridge, a distance of 1 mile, although the water is shallow and the bottom rough, it is not, on the whole, more so than between gauges 1 and 2 on the Forth; but at the Dornoch the slope on that mile is no less than 6 feet 6 inches, and the rate of propagation is only two-thirds of a mile per hour. Moreover, it was found that the tide did not begin to show at Bonar until it had risen 6 feet 6 inches on the gauge at the Quarry, being the exact difference of level between the two points of observation.

These various results as to slopes and rates of propagation, as well as others which have come under the writer's notice, seem to justify the following deductions as to the propagation of the tide-wave in rivers with sloping surfaces and irregular bottoms:—1st, That a decrease of slope is followed by an acceleration of the rate of propagation of the tidal wave. 2d, That an increase of slope is followed by a retardation of the rate of propagation. 3d, That the rate of propagation does not bear any constant relation to the amount of slope, although it is to some extent modified by it. 4th, That while the rate of propagation in rivers is in some measure due to the depth of water, it is nevertheless influenced by the slope of the surface, the form of the channel, and the obstructions protruding from the sides or bottom. 5th, That if not in all cases, at least when there are steep slopes and shallow water, as at the Dornoch Firth, the level of the crest of the wave must rise to the level of the surface of the water (or perhaps the bed of the river) above it, before a progressive motion takes place; and, 6th, That, from the difficulty of dealing with so many variable elements, it is impossible in most rivers to determine the ruling circumstances which can be held as regulating the rate of tidal propagation.

The Clyde affords a striking proof of the extent to which river improvements may be carried. So insignificant was the stream in its natural state, that Smeaton, in 1775, proposed to erect a dam with locks in the lower part of the river, and to convert it into a tidal canal. In 1775, however, Golburne surveyed the river, and although he found that as far down as Kilpatrick the depth of water was only 2 feet, he nevertheless recommended the construction of a series of jetties from either side, for the purpose of narrowing and deepening the stream; and this may be held as the commencement of the improvement of the River Clyde, which originally barely afforded depth of water for larger craft than flat boats, but which now, as our readers know, admits vessels of large draught up to Glasgow Bridge. The reader must be cautioned from supposing, however, that this result has been attained by means of the jetties which were erected under the advice of Golburne. It was soon discovered that the object could not be gained by such

Rivers.

Clyde.

Rivers. works. It was not until the ends of the jetties were connected by longitudinal walls, and until dredging-machines were extensively employed, that the Clyde improvements began to assume an importance commensurate with the vast commercial interests of the city of Glasgow and surrounding districts. The works on the Clyde have latterly been under the direction of Mr Walker, and have mainly consisted in forming longitudinal walls, dredging, and increasing the width of certain parts of the channel, which had in the early stage of the improvements been contracted to an injurious extent.

River Ribble.

The Ribble in Lancashire, the improvements of which were designed by Messrs Stevenson, presents an example of a great amount of additional depth having been obtained in a comparatively short space of time. That river, according to Mr Park, who conducted, as resident engineer, the greater part of the works, has a course of 82 miles, and drains 900 square miles of the counties of York and Lancaster. The formation of the bed in which it flows rendered the state of the tidal compartment previous to the improvements very defective. The bottom in the lower part of the river consists of loose sand; while that of the upper reach is alternately compact gravel and sandstone rock. About half a mile below Preston, in particular, it was found that a solid ridge of sandstone, extending to 300 yards in length, stretched quite across the channel. Its surface was from 3 to 5 feet higher than the general bed of the river both above and below it, and so prominent an obstruction did it form, that the higher parts of the rock were occasionally left dry during the long droughts of summer. The propagation of the tidal wave, and free flow of the currents, were checked on approaching it; while the power of the tidal and fresh-water scours was in a great measure neutralized and rendered almost unavailable in keeping open the upper and lower stretches of the navigation; so that its influence in obstructing the river resembled that of a great artificial weir stretching across the stream. In proof of this, it may be stated that the ordinary rise of spring tides at Lytham, which is 12 miles seaward of Preston, is about 19 feet,¹ and that of neap tides is 14 feet, while at Preston, prior to the operations, the rise of spring-tides did not exceed 6 feet, and neap tides of 13 or 14 feet rise at Lytham did not reach Preston at all. The removal of the rock which encumbered the bed, was naturally viewed as the most urgent and important work for effecting an improvement in the tidal phenomena and general depth of water. To this, therefore, the Navigation Company first directed its attention, and in the course of eighteen months, succeeded in excavating a channel through the solid rock 300 yards in length, and in some places 13 feet 6 inches in depth. This operation was successfully accomplished, at an expense not exceeding L.10,000, by means of a coffer-dam of the construction already shown in fig. 8. In addition to this work, about 480,000 tons of gravel and sand have been removed from the upper part of the river by dredging; and 9 miles of low rubble walling (formed, in so far as it was available for the purpose, of the rock excavated from the bed of the river) have been constructed in accordance with the sketch shown in fig. 15, for guiding the current in the lower channel.

The effect of the different works that have been executed has been to increase the tidal range at Preston about 5 feet, and to accelerate the propagation of the tidal wave nearly an hour; and vessels, to which the navigation may be said to have been previously closed, now come up to the quays of Preston with comparative ease and safety.

The works on the Lune in Lancashire were executed by

Messrs Stevenson, under the direction of the Admiralty. They extended over a period of four years, and consisted in removing fords by dredging, shutting up subsidiary channels, and erecting river walls; the whole operation costing under L.10,000. The sketch of the Lune in fig. 9 shows the varying state of the channel in its original condition, which was regulated by means of a single rubble wall, as the funds did not admit of a double wall being erected. It was necessary also, from the configuration of the shores, that the channel should follow the convex side of the wall which should, if possible, be avoided, as some difficulty occurs in maintaining the channel always close to the wall,—a difficulty which can only be removed by the formation of a second wall; and we mention this as an example of the desirableness, as already stated, of forming double walls in all cases when the funds at disposal will admit of it. Fig. 17 represents the gradual depression of the tidal lines

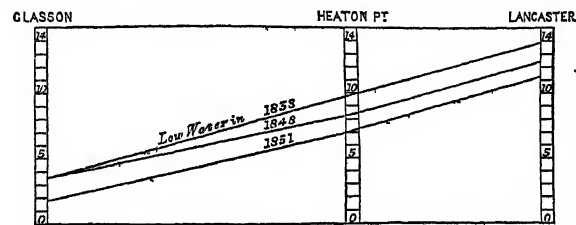

Fig. 17.

since the works commenced: the upper line shows the surface of the river in 1838, the intermediate line in 1848, and the lower line in 1851. The effect of the works has been to increase the depth of water up to the quays at Lancaster about 4 feet, and to prolong the duration of the tidal influence at that place thirty minutes in neap, and one hour and a half in spring tides; so that vessels can approach and leave Lancaster much earlier than formerly, while the improved channel is navigated with much greater ease.

It is unnecessary to give farther examples of navigations which have been benefited by means of works constructed on the principles which we have indicated. We doubt not that such cases could be quoted, although we do not possess sufficient details to enable us to do so; and we close this part of our subject by stating that the further extension of these works in such rivers as the Tay, the Ribble, or the Lune, and their application in many other cases, would be followed by a greatly increased improvement of their navigation.

Instances might be referred to where a course of treatment opposed to that which we have recommended has not been followed by similar favourable results; but we deem it sufficient to confine this treatise to an exposition of the correct principles of river improvement, without discussing erroneous practice or its baneful results; the more so as these have been most fully and ably treated by Mr E. K. Calver, R.N., whose investigations into the former and present state of some of our tidal rivers are of great value to the hydraulic engineer.²

SECT. VI.—SITUATIONS WHERE THE PRINCIPLES OF IMPROVEMENT RECOMMENDED ARE NOT APPLICABLE.

We have further to state, that in some situations the principles of improvement which we have advanced will be found to be of very limited application. Such cases indeed are rarely to be met with, but still it is necessary to notice them. We allude to rivers the tidal or intermediate compartments of which are, from natural causes, of very small extent. In illustration of what we mean, we may refer to

¹ Captain Sir Edward Belcher, while engaged in making the Admiralty survey of the Ribble, found that on one occasion the tide at Lytham rose 25 feet 7½ inches.

² *The Conservation and Improvement of Tidal Rivers*, by E. K. Calver, R.N., London, Weale, 1853.

River Lune.

Rivers.
The Erne. the Erne in Donegal, which has a tidal capacity of only $2\frac{1}{2}$ miles, extending from the bar up to the town of Ballyshannon, where the tidal flow is terminated by the "Salmon Leap," a perpendicular rise in the bed of the river of about 15 feet in height. This waterfall forms the limit of the tidal flow, beyond which it could not, without works of a gigantic character, be extended.

The Ness. Another case is the Ness, which has a short course of about 2 miles, from a little above the town of Inverness to the Beaul Firth, at Kessock Roads. The difficulties attending the navigation of this river are mainly the prevailing outward currents due to the physical conformation of the bed of the Ness, which may be shortly described, as it illustrates generally a class of rivers which are very difficult to improve:—1st, The rise of ordinary spring tides at the mouth of the river is 14 feet. 2d, The distance to which the influence of such tides extends is only about 2 miles, which includes the whole tidal compartment of the river. 3d, The slope or inclination of the low-water line of this tidal compartment is no less than 7 feet per mile, and the tide takes from two to three hours to make its way up the first mile. 4th, The natural result of such a state of matters is, that no tidal current is generated at the mouth and propagated up the stream, and consequently the phenomenon of a current due to flood-tide may be said to be almost unknown.

Under these circumstances, the barrier to the free navigation of the River Ness is the absence of a tidal current or in-draught, to aid the entrance of vessels from Kessock Roads, and assist their progress up to the quays. This is at present effected by help of men and horses against the nearly constant downward current, which varies in strength with the amount of water discharged by the River Ness, during its frequent heavy floods.¹

Back-water. This absence of sufficient internal capacity and gentleness of inclination to admit of the generation of tidal currents is strikingly exemplified in the two rivers to which we have alluded, and naturally leads us to offer some general remarks in passing on the subject of the "backwater" and the "slopes" of rivers. In most, if not in all cases, it will be found (as more particularly noticed hereafter in section 8, in treating of bars) that it is of the highest importance to maintain unimpaired the full tidal capacity, and to be careful to make no reduction of its amount without obtaining an equivalent in the low-water section, to compensate for any reduction which it may be found advisable to make at or near the high-water line.

The subject of the reduction of backwater has given rise to various questions, which have occupied the attention of the engineer; but as every case must be judged on its own merits, and no two situations are exactly alike, it would be unprofitable to enter upon the discussion of the various

arguments that have been adduced with reference to particular localities. All we can do is to lay down the general principle, that the more the tidal influence can be extended, and the larger the amount of backwater that can be obtained, the greater will be the benefit conferred on the navigation from the bar upwards; provided always that such increased scouring power is, by judicious works, placed under proper regulation. The question as to the possibility of excluding the tide from any part of an estuary, without injury to the outer channels, is a wide subject, as will be seen from our merely stating some of the considerations which may be held to determine the peculiar circumstances in which the exclusion of water may be compensated. These are, the configuration of the banks and bed of the estuary, the simultaneous levels of the surface of the water at different periods of the tide throughout the estuary, the velocities of the surface and under-currents at different periods of tide, and the times of ebbing and flowing, together with many other more minute data *peculiar to each case*, which it is not possible to specify in a general summary.

The existence of a moderate amount of fall or slope on the low-water line of a river is a hopeful feature in its capabilities for improvement; while on the other hand, such a slope as that on the Ness proves a great barrier to its extended improvement as a tidal river; for it is obvious, that to obtain on that river a slope sufficiently gentle for easy navigation, it would be necessary to lower its bed to so great an extent, and to execute works of such magnitude, as to render it inexpedient to entertain such a project.

The consideration of the proper slope is important in river engineering. Dubuat considers 1 in 500,000 to be the smallest possible inclination that can be given to a canal to produce sensible motion. It will be found, on inspecting the table at the end of this treatise, that the slopes of tidal rivers vary from a few inches to several feet per mile.² As a general rule, we should say that the engineer may calculate on reducing the slopes of tidal navigations to 4 inches per mile = $1:33\frac{1}{3}$; and that they should not, if possible, exceed 10 inches per mile = $1:6\frac{1}{2}$.

Directly connected with the slope is the velocity of streams, —an important matter as affecting navigation, for it cannot be conducted with advantage in situations where the velocity of the currents is very great. The velocities of tidal currents in some places are very great; as, for example, in the Pentland Firth, where Captain Otter measured a velocity of 10·8 miles per hour, and in the Severn, where it was found to be 9 miles per hour. From 2 to 3 miles per hour is, however, a very common velocity on many of the rivers in this country, and it is found to present no inconvenience to the navigation of vessels. The following are the velocities of the currents in different rivers, with their authorities. The whole of them are surface velocities:—

Name.	Per Hour.	Authority.	Name.	Per Hour.	Authority.
Mississippi	Miles, yds. 5 0	Ellet.	Severn, near Stonebench, ebb	3·12	Admiral Beechy.

² The slope of the river Niagara at the rapids, immediately above the far-famed "Falls," is said to be 50 feet in half a mile, or 1 in 52·8.

Rivers.

SECT. VII.—WORKS FOR ACCOMMODATION OF VESSELS.

The works we have described are for facilitating the ingress and egress of vessels. In addition to this, it is necessary to provide for their accommodation. For this purpose it is desirable, where local circumstances admit of it, that it should be possible to withdraw them from the action of the river currents which, during heavy floods accompanied by ice, are often very destructive to shipping.

Tide-basins.

This is accomplished in a simple manner by forming what are termed tide-basins, which are artificial cuts retiring from the stream having their sides bounded by quays or wharves, into which vessels may be withdrawn, but where they are still liable to take the ground at low-water. The object is accomplished more effectually by means of wet docks, for details of which the reader is referred to the article on that subject. In many situations, however, especially where the river is wide, and affords ample room, as in the case of the Foyle at Londonderry, for example, the berthage for vessels is afforded by means of lines of quays formed along the shore.

River quays or wharves.

Such quays constitute an important part of all harbours which are formed in tidal rivers; and in illustration of some of the various methods of construction adopted in such cases we submit the following cross sections. Fig. 18 shows the timber wharfage constructed by Mr Smith at Belfast,

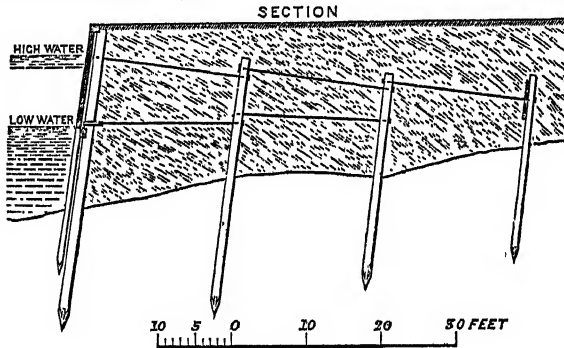

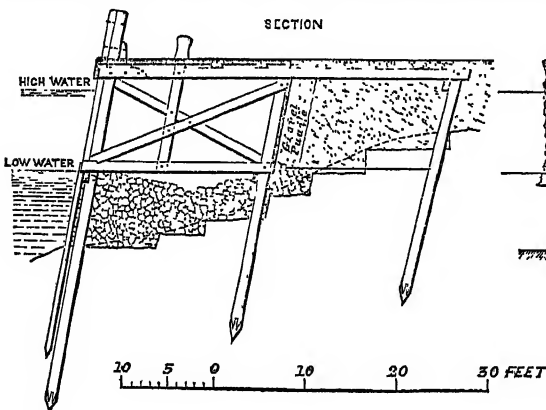

Fig. 18.

which is composed of a facing of timber-work secured by iron ties fixed to piles, the space behind the face-work being filled up, and the roadway formed at the top. Fig. 19 is

Fig. 19.

a plan showing the positions of the piles and ties. Sometimes a similar face-work is employed, backed by a wall of concrete; and iron plates have also been used for the facing,

Figs. 20 and 21.

instead of planking. Figs. 20 and 21 are a section and elevation of the quays of Londonderry, designed and executed

by Messrs Stevenson. At this place the ground is very soft,

Rivers.

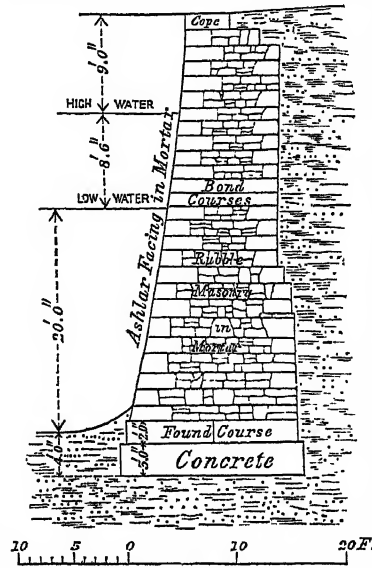

Fig. 22.

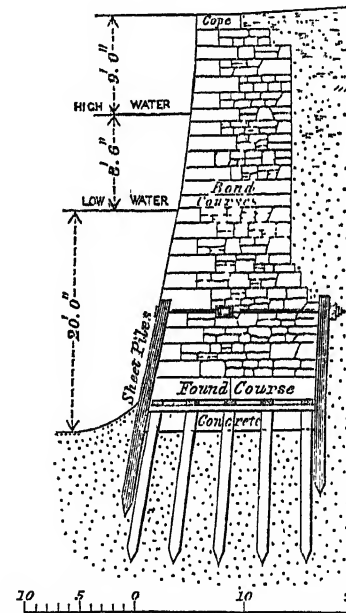

Fig. 23.

and in order as much as possible to reduce the weight, the front compartment of the wharf next the river is left open. Figs. 22 and 23, again, are sections of the stone wharves now being constructed from a design by Mr Walker, at Glasgow, under the superintendence of Mr Ure. Fig. 22 is the section adapted to a clay bottom; and fig. 23 is that which is adopted when the bottom consists of sand. In both cases the depth of water in front of the quays is 20 feet at low-water, and is intended to accommodate merchant vessels of the largest class. These examples furnish an illustration of the means employed for providing wharfage on tidal rivers; the details of their construction must be studied in treatises on such branches of engineering construction as Carpentry, Masonry, Piling, Foundations, Mortar, and Quay Walls.

The engineer is often called on to construct swing-bridges in connection with navigations, but for particulars as to such works, reference is made to the article IRON BRIDGE.

SECT. VIII.—“SEA PROPER” DEPARTMENT OF RIVERS.

Having considered the treatment of rivers from their source to the ocean embracing the upper or “river proper,” and the intermediate or “tidal compartment,” we have now to direct attention to what we have termed the “sea proper” compartment, which, in the sense we have attached to it, may be said to embrace the phenomena connected with the flow of rivers or bodies of tidal water into the sea.

In some instances, such, for example, as the Forth, the junction of the river with the sea occurs without giving rise to any very

perceptible or marked phenomena; the one seems to glide naturally into and be mingled with the other, without producing any apparent disturbance of the currents or

Bars.

Rivers.

change on the bed of the channel. But such cases are exceptions; and, generally speaking, we may safely affirm that the junction of a river with the sea gives rise to what is termed a "bar,"—the most difficult subject with which the hydraulic engineer has to grapple, and the nature and cause of which we have now to discuss.

A bar, then, is the name applied to that shallow part of a channel which occurs at the junction of a river or estuary with the sea. On either side of it—that is, both seaward and landward of it—there may be ample depth of water for all purposes of navigation, but the bar forms the regulating navigable depth, and no passage over it can be obtained until the tide has risen sufficiently high to enable vessels to cross it. The depth at low-water on the bars of some of our rivers is as follows:—

The Mersey has a depth of from	9 to 10 feet	at low-water.
" Tyne.....	6 to 7	do.
" Wear.....	3 to 4	do.
" Ribble.....	7 to 8	do.
" Tay.....	16 to 18	do.

And while these limited depths exist on the bar, there is in all of these cases ample depth within, or landward, for vessels of the largest class to lie afloat at all times of tide.

Theories to account for formation of bars.

Many theories have been propounded to account for the phenomenon of the bar. Some have advocated the idea that bars are composed of materials held in suspension by the river, and deposited so soon as its current is checked by meeting the still water of the ocean. But this theory, at all events as regards sea bars, of which we are now treating, is disproved by the facts of the Dornoch Firth, to which we have already alluded. The bar at that place occurs at a point 14 miles seaward of the point at which the river enters the sea. The idea that a bar of such magnitude as that at the Dornoch Firth, could be formed by the detritus brought down by the small rivers Oykel and Cassily, is wholly untenable, and is indeed contradicted by the fact that the bar and adjoining banks are composed of pure sand; and hence the writer attributed its formation, when he examined the firth in 1842, entirely to the action of the sea. We find that Mr Ellet, though founding his opinion on totally different premises, also comes to the conclusion that the bars of the Mississippi were not due to materials deposited by the outgoing stream. In explaining his views, he writes as follows:—"The velocity of the river is not destroyed, nor very sensibly diminished, at the bars. When the river was rising, but still far from being at full height, I measured the velocity of the current on the bar of the Passàla Loutre, and found it to vary, at different times and places, from 3 feet to 3½ feet per second, or from 2 miles to 2½ miles per hour. I measured it also repeatedly on the south-west bar, and found it there 3 feet per second, or about 2 miles per hour. But there are many parts of the river where the speed of the current does not exceed 2½ miles, or even 2 miles per hour, in times of flood, and where it is, notwithstanding, more than 100 feet deep. In fact, on testing the velocity of the south-west pass, 4 miles above the bar, and in 5 fathoms water, I found the current to be but 2 miles per hour,—precisely the same as it was under like circumstances of wind and tide on the bar. The current of the Mississippi sweeps over the bars at the mouths of the passes, and at periods of flood many miles out into the gulf, with a velocity almost undiminished by its contact with the waters of the gulf." He therefore concludes that there is in the Mississippi no retardation of the river's velocity on the bar to account for any deposit due to such a cause. Another theory attributes bars to the want of sufficient scouring power; but when we find bars existing

at the mouths of such rivers as the Mississippi, we cannot attach much importance to such a suggestion. Another theory attributes the *absence* of a bar to "the presence of a nearly equal duration of the period of the ebb and flow in the lower reach of the river accompanied by an extremely gentle inclination of its surface at low water."¹ To refer again to the Dornoch Firth, we have an equal duration of the ebb and flow throughout the firth, and a surface practically level, and yet we have as perfect a specimen of a bar at the Gizzen Briggs, at the mouth of the firth, as can possibly be imagined. We cannot, therefore, in endeavouring to account for the existence of bars, or the exemption from them, accept the explanations to which we have alluded.

The bars with which we have to do in this country may be said to be of two kinds; one class of bars is due to the hard formation of the bottom, which occurs in some situations; the other class is due to the action of certain elements, on the soft matters of which the bottom in other places is composed. Of the first class are such bars as that at Ballyshannon in Ireland, or at the entrance of Loch Fleet in Sutherlandshire, both of which the writer has had occasion professionally to examine. The bar at Loch Fleet, for example, is composed of boulder stones firmly imbedded in a mass of indurated gravel, and is obviously a continuation of a bed of similar formation which seems to traverse the coast at that place. The consequence is, that no scouring power can prove available in deepening the channel. Such bars being entirely due to the hardness of the bottom, are generally comparatively easily treated by the engineer, and an encouraging prospect is held out that their removal will be attended with permanent benefit, since, by excavating a channel through them, the engineer at the same time removes the evil and its cause.

In the other class are comprehended those sand-bars which occur at the mouths of the firths of Dornoch and Tay, and of the Tyne, Wear, Mersey, Ribble, and other tidal rivers and estuaries; and it is to the formation of these capricious and troublesome accumulations that the theories to which we have alluded apply. The true source of all such bars is to be found, as already stated, in the action of the sea. The natural effect of the sea is to throw up sand, and form a continuous line of beach across the mouths of all our tidal rivers and inlets; while, again, the flow of the tidal and fresh-water currents tends to maintain an open channel through the beach. In this way the antagonistic action of the waves of the sea on the one hand, and the currents of the estuary or river on the other, produce the well-known feature of a submerged beach or sand-bank, extending from shore to shore across our inlets, having a deeper channel through them, which channel is termed the "bar." This explanation is due to the Abbot Castelli, who, in his work on the Mensuration of Running Waters, written in the beginning of the seventeenth century, gives the following clear announcement of his views:—"As to the other point of the great stoppage of ports, I hold that all proceedeth from the violence of the sea, which being sometimes disturbed by winds, especially at the time of the waters flowing, doth continually raise from its bottom immense heaps of sand, carrying them by the tide and force of the waves into the lake; it not having on its part any strength of current that may raise and carry them away, they sink to the bottom, and so choke up the ports. And that this effect happeneth in this manner, we have most frequent experience thereof along the sea-coasts; and I have observed in Tuscany, on the Roman shores, and in the kingdom of Naples, that when a river falleth into the sea, there is always seen in the sea itself, at the place of the river's outlet, the resemblance, as

Rivers.

¹ *Treatise on the Improvement of the Navigation of Rivers*, by W. A. Brooks.

² *The Mensuration of Running Waters*, by Don Benedetto Castelli, Abbot of St Benedetto Aloysio, and professor of the mathematics to Pope Urban VIII. in Rome; translated by Thomas Salusbury, Esq., London, 1661.

Rivers. it were, of a half-moon, or a great shelf of settled sand under water, much higher than the rest of the shore, and it is called in Tuscany *il cavallo*, and here, in Venice, *lo seanto*; the which cometh to be cut by the current of the river, one while on the right side, another while on the left, and sometimes in the midst, according as the wind fits. And a like effect I have observed in certain little rilletts of water along the Lake of Bolsena, with no other difference save that of small and great.

"Now whoso well considereth this effect, plainly seeth that it proceeds from no other than from the contrariety of the stream of the river to the impetus of the sea-waves; seeing that great abundance of sand, which the sea continually throws upon the shore, cometh to be driven into the sea by the stream of the river, and in that place where these two impediments meet with equal force, the sand setteth under water, and thereupon is made that same shelf or *cavallo*; the which, if the river carry water, and that any considerable store of it shall be thereby cut and broken, one while in one place, and the other while in another, as hath been said, according as the wind blows; and through that channel it is that vessels fall down into the sea, and again make to the river, as into a port. But if the water of the river shall not be continual, or shall be weak, in that case the force of the sea wind shall drive such a quantity of sand into the mouth of the port and of the river as shall wholly choke it up. And hereupon there are seen along the sea-side very many lakes and meers which at certain times of the year abound with waters, and the lakes bear down that inclosure, and run into the sea.

"Now it is necessary to make the like reflections on our ports of Venice, Malamocco, Bandolo, and Chiozza, which in a certain sense are no other than creeks, mouths, and openings of the shore that parts the lake from the main sea; and therefore I hold that if the waters in the lake were plentiful, they would have strength to scour the mouths of the ports thoroughly and with great force; but the water in the lake failing, the sea will, without any opposal, bring such a drift of sand into the ports, that if it doth not wholly choke them up, it shall render them at least unprofitable and impossible for barks and great vessels."

Conditions under which bars are formed. The conditions under which such accumulations are formed the writer holds to be,—1st, The presence of sand or shingle, or other easily moved material; 2d, Water of a depth so limited as to admit of the waves during storms acting on the bottom; and 3d, Such an exposure as shall allow of waves being generated of sufficient size to operate on the submerged materials.

In confirmation of this opinion, we may once more refer to the Dornoch Firth. The Oykel joins it at a point about a mile below Bonar Bridge, but we find no indication of what may be termed a bar throughout the whole of the sheltered part of the firth, which extends for 12 miles seaward of that point, until we reach the outer portion which is exposed to the unbroken sea of the Moray Firth, and there we find an extensive sand-bank, forming as it were, a continuation of the shore on either side, and stretching quite across the mouth of the firth, with the bar in the centre of it. But the fact, that in all such bar-rivers and estuaries the depth is often found to be seriously diminished after heavy seas, is beyond doubt, and serves as a further confirmation of the correctness of the theory for which we are contending.

The same reasoning may explain why, in such a case as the Firth of Forth, for example, no bar exists. The Firth of Forth is an inlet or arm of the sea, of great width and depth, the seas entering it do not act on the bottom, so as to

cause a heaping up of the material of which it is composed, in the same manner as in a shallow sea. This great natural depth continues as the Forth gradually contracts; and before the necessary conditions for the formation of a bar occur—namely, sufficiently shallow water and presence of sand—the sea is so land-locked that waves of sufficient size to produce the necessary effect cannot be generated. There is, in fact, in the Forth that gradual diminution of depth, and increase of shelter, which combine to produce the phenomenon of a river without a bar.

We must also notice a cause for the formation of bars advanced by Mr Ellet. Although it is not applicable to the rivers in this country, still, from the observations he has made, we think it likely that his theory may be held to account for the bar of the Mississippi. It is founded on the fact, that at the junction of a river with the sea the fresh water flows in a stratum above, and distinct from, the salt water, for some distance after entering the ocean. This is occasioned by the higher specific gravity of salt water, the weight of fresh water being 1000, while that of salt is 1026. **Relative specific gravities of salt and fresh water.**

Before noticing Mr Ellet's theory, however, we may state, that so far as we are aware, the first observations made on this subject were those instituted by the late Mr Robert Stevenson, of Edinburgh, on the River Dee in Aberdeenshire, in the summer of the year 1812, while engaged in surveying that river with reference to a disputed right of salmon-fishing. Mr Stevenson, in his report on that subject, states that, by means of an instrument devised for that purpose, he ascertained that the salt or tidal water of the ocean flowed up the channel of the River Dee, and also up Footdee and Torryburn, in a distinct stratum, next to the bottom and under the fresh water of the river, which, owing to the specific gravity being less, floated upon it, continuing perfectly fresh, and flowing in its usual course towards the sea, the only change discoverable being in its level, which was raised by the salt water forcing its way under it. The tidal water so forced up continued salt; and when the specific gravities of specimens from the bottom were tried, they were found to possess the greater degree of specific gravity due to salt water, while the surface specimens were found to be specifically unaltered. **Experiments at the Dee.**

Similar observations have been made by the writer of this article in several places, with the same results. The appearance of fresh water floating on the surface of the sea is no doubt familiar to most persons. It occurs at the mouths of many of our rivers, and is most apparent when they are in flood, from the brown tinge given to the water, which is easily discoverable for many miles at sea. It is well known on our coasts to the crews of the welled smacks employed in cod-fishing, who invariably lose a great portion of their live stock if they happen to encounter what they term "a fresh," which is believed by them to be a brackish portion of the sea, caused by the imperfect admixture of fresh water discharged from rivers in flood. On this subject the following passage from the work¹ of Father Manuel Rodriguez, a Spanish Jesuit, is interesting, and its correctness, as regards the extent to which the influence of large rivers is felt, has since been corroborated by the investigations of Colonel Sabine.² "This river," says Rodriguez, speaking of the Amazon, "is like a tree; its roots enter as far into the sea as into the land. It communicates to it a flavour, so that at 80 leagues within the sea its waters are seen, and taste sweet, and in a semicircle of 100 leagues in circumference they form a gulf not the least degree brackish, so that sailors call it the fresh sea."

But to return to the Mississippi: Mr Ellet, in the following extract, says:—"The river water does not mix suddenly

¹ *El Maranam y Amazonas*, Madrid, 1684, p. 18.

² *An Account of Experiments to determine the Figure of the Earth, as well as on various other subjects of Philosophical Engineering*, by Edward Sabine, London, 1835, p. 445.

Rivers.

with the sea, but rises upon it, floats over it, and rushes far out into the gulf on the top of the dense sea water, by which it is buoyed up. I tested this repeatedly, and found uniformly a column of fresh water, nearly 7 feet deep, in the gulf, entirely outside of the land, and salt water at a depth of 8 feet from the surface, and extending thence to the bottom. The river does not come down with a certain normal depth and speed, and encounter the gulf at the bar. No such process takes place. There is no sudden destruction of velocity, or consequent deposit of suspended silt. But the water of the Mississippi does not move over the surface of the gulf at a speed of 3 feet per second without imparting a portion of its motion to the sea.¹ The fresh water and the salt water take the same direction towards the sea, and with nearly the same velocity, but yet keep separate. This state of things clearly cannot exist at the bottom; for as the river water is for ever coming forward, if the salt water all flowed towards the gulf, it would all be carried out, and river water would take its place. Salt water must come in from some quarter, to supply the current of sea water that is for ever setting towards the gulf, beneath the water discharged by the river. This salt water can only come from the sea, and can only come in along the bottom. It is, in fact, an eddy that is here at work, the movements being in a vertical instead of a horizontal plane. Now, the question is, How does this account for the existence of the bar? The fresh water running out cannot produce deposit, for it has velocity enough to sweep away a foundation of coarse gravel. The outpouring salt water, immediately beneath the fresh, cannot produce deposit, because it also has a velocity seaward strong enough to remove anything that is brought down the Mississippi. The salt water that is coming in might produce, and I doubt not does produce, a deposit, for it passes over the soft muddy bottom of the gulf, and moves into the river, and along the bar, at a very slow rate. According to these facts, and this reasoning, there must be usually on the bar three distinct strata: 1st, Fresh water, running out at top, found by experiment on the S.W. bar to have a velocity of 3 feet per second. 2d, Salt water below the fresh, also running out with nearly the same velocity as at top; and 3d, Salt water coming in slowly along the bottom, and apparently a sheet of salt water between that running out and that coming in, which will be without motion.

"But as already said, and as is obvious, all the sea water that comes in must go out again. It comes in along the bottom, and it must go out between the column of salt water coming in and that of the fresh water going out. Each particle of salt water, therefore, must change its direction and position in elevation. It must pass from an inward-bound lower stratum to an outward-bound upper stratum. But in passing through this change of motion, its velocity up stream must be neutralized. It passes, to use a technical term, the *dead point*. At this point it may cease to bear its whole burden of mud, which it has brought from the gulf further forward. It leaves it, or a portion of it, at the turning-point. This turning-point is the place where the bar for the time being is in process of formation. But as the upper and lower strata are moving in opposite directions, the intermediate column must of necessity have a rotatory motion; that motion must be shared by the lower column of salt water, and this turning-point must therefore be found at the same time at different places along the bar."

Mr Ellet gives an interesting detail of his experiments on the saltness and freshness of the water, as taken from different depths, and also of the means he took to ascertain the strength and directions of the two under-currents re-

ferred to in his ingenious theory of the formation of the bar; but the details are too long to give in this sketch of his researches. Rivers.

We have seen that bars, in some situations, are formed by the hard strata of which the bottom is composed; that in other places they are due to the waves of the sea; and that in the case of the Mississippi Mr Ellet attributes the phenomenon entirely to the eddy caused by an under-current inwards.

The removal of *hard bars* is, as already noticed, likely in most cases to result in a successful issue; but the treatment of those bars which are due to the waves of the sea, with which class of phenomena we have chiefly to do in this country, is an operation not only more difficult to deal with, but far more uncertain in its results.

From what has been said, the reader will see that we believe the depth of water, on such bars as are caused by the waves of the sea, to be in some degree proportional to the scour produced by the tidal currents, which cross them four times in every twenty-four hours. If this assumption be correct, it is obvious that the principle which should guide us in all our considerations as to increasing, or even maintaining the depth upon sea-bars, is the preservation of a sufficient amount of tidal water to counteract the tendency of the sea to heap up detritus at the mouths of our harbours. These two agents, the *waves* and the *tidal scour*, are constantly opposed the one to the other: a storm from the sea, or a heavy flood from the land, occasionally causes the one or the other to have the ascendancy; but this is only temporary. A variation in the depth of water on the bars of our harbours, caused by such temporary disturbances, may occasionally occur; but nevertheless, unless some work of magnitude is formed, so as to alter permanently the natural disposition of matters, no pilot has any difficulty in fairly estimating what is the general navigable depth over the bar of any of our seaports.

That the beds of the upper parts of rivers are scoured, and their depth maintained by the flow of the fresh-water stream, is not to be questioned; and it is also beyond doubt, that in many situations the upper portions of the tidal compartments of rivers are kept open in a great measure by the fresh-water stream; but it is no less certain that the opinions which would assign the depth of water in the lower parts of tidal rivers, and also through estuaries and across bars, to any other cause than the action of tidal water as the chief agent, are erroneous. We think this will be apparent by a reference to some of the investigations which have from time to time been made to ascertain the amount of the river or fresh water, as compared to the volume of the tidal water of some of our firths and estuaries. Comparison of amount of river and tidal water in firths and estuaries.

By means of a series of careful observations and measurements made at the Cromarty Firth in 1837, to which reference has already been made, Mr Alan Stevenson found that the River Conon, when highly flooded (a state of matters which of course occurs only occasionally), discharges during twelve hours a quantity which is only equal to $\frac{1}{11}$ th part of the water which passes out of the firth at every ordinary spring tide, and $\frac{1}{15}$ th of that which passes out at neap tides. While in its summer-water state, the produce of the river is reduced to $\frac{1}{111}$ of the discharge of the firth in spring, and $\frac{1}{11}$ of the discharge in neap tides; a quantity too small to affect appreciably either the velocity of the currents of the firth or their scouring power. It has often been argued, that in situations where the velocity of the ebb exceeds that of the flood tide, the excess is due to the increased quantity of water passing out with the ebb, the volume of the ebbing waters being assumed to be augmented by the amount discharged by the river. But this

Depth of water due to amount of back-water.

Comparison of amount of river and tidal water in firths and estuaries.

Cromarty Firth and River Conon.

¹ This is in harmony with Venturi's well-known experiments, from which he found, that a body of water in motion leads or drags with it the particles of water at rest with which it may be in contact.

Rivers. is wholly disproved in the case of the Cromarty Firth; for while the increased quantity due to the river is seen to be only from $\frac{7}{8}$ to $\frac{1}{8}$, the average velocity at the flood-tide at that place was found to be 2.9 miles per hour, while that of the ebb was 3.6; an increase which is in all probability due to the tide beyond the Suters falling more rapidly than it rises, and thus producing a greater head and more rapid current on the ebb, but is assuredly not due to any augmentation of water from the discharge of the Conon.

The Tay. The Tay presents another example of the disproportion between the tidal and river waters. That river, as gauged by Mr Leslie when in flood, was found, including the Earn, to discharge 969,340 cubic feet per minute. Mr Walker, in his report to the trustees of Dundee harbour, assumes the discharge in round numbers at one million cubic feet per minute, or 240,000,000 during four hours, and arrives at the following conclusion:—"To compare the above with the effect of the tidal water at Dundee, I assume 15,000 acres as the average area (above Dundee) of the reservoir or estuary during the first four hours of the ebbing tide, and the vertical fall of tide during these four hours to be 11 feet. This will give 7,187,400,000 cubic feet, or thirty times the 240 millions of river water. To compare the effect upon the bar, the area of the river between Dundee and the bar must be added; and the tidal water upon the bar will then be upwards of *forty times* the river water."

Works recommended favourable for bars. It will be apparent that an important question is suggested as to the manner in which such works as we have recommended for improving the upper parts of rivers may operate in assisting or retarding the scour of the bar. We have no hesitation in replying, that if executed in the manner we have indicated, they will improve the higher part of the river without prejudicially affecting the bar, and in certain cases they will operate beneficially on the bar also.

Piers for entrance to rivers. The construction of piers for improving the entrances of rivers, as in the case, for example, of the Wear at Sunderland, is more properly included in the subject of harbours. Such works seem to us to act beneficially, not so much by increasing the *depth* on the bar, as by limiting the extent of shoal water at the entrance to the river. In its natural state such a river as the Wear flows across the beach from high to low water in a broad and shallow channel, the direction of which is ever changing. It thus forms a long bar or shoal, with broken water throughout its whole extent. But the projection of piers across the beach affords shelter from the waves, and admits of a navigable channel being excavated and maintained; and after a vessel crosses the short bar, which occurs at or near the pierheads, she not only gets into deeper water, but has the additional advantage arising from the shelter afforded by the piers. To this extent piers in such situations are highly advantageous. They further act beneficially in directing the flow of the tidal currents in a fixed channel across the beach and bar, and, in connection with an increase of tidal capacity in the interior, such as we have mentioned as the result of the works on some rivers, they cannot fail, if judiciously designed, to operate beneficially by maintaining an increased depth of water on the bar.

Groynes. In certain situations where the coasts are faced with gravel or shingle beaches, accumulations or bars may be lessened by means of groynes, so formed as to intercept the gravel, and either retain it, or lead it past the harbour's mouth into an adjoining bay. The writer has in several situations recommended the adoption of such works; and Mr Walker has applied them with success at the harbour of Newhaven in Kent, where, in conjunction with increased backwater, due to deepening and removal of obstructions, the depth on the bar has been materially increased.

Rivers. Such twofold schemes as have for their ostensible object the improvement of rivers and the *formation of land*, have generally been unsuccessful in benefiting navigation. We do not affirm that river-works, constructed on the principle which we have advocated, have not the effect of *making land*, in the particular sense in which we shall afterwards explain it; but we do state that *land-making* is no part of sound *river engineering*. Judiciously designed works may, as we shall presently explain, have the effect of reclaiming and protecting land, while at the same time they, as their primary object, benefit navigation; but we know of no case where the interests of navigation have been promoted by any measure which has for its object the conversion of large tracts of tide-covered sands into cultivated fields.

We refer to the Dee in Cheshire, as an aggravated instance of the incompatibility of the two interests.¹ The outline of this river is shown in Plate I., from a survey by Messrs Stevenson, made in 1838. The River Dee Company, incorporated by act of Parliament in 1732, have from time to time reclaimed from the upper part of the estuary a large tract of land, extending to about 4000 acres, which is now in full cultivation; and alongside of this gradually gained territory the river has been conducted from Chester to near Flint, in a narrow canal of about 8 miles in length, and 400 feet in width. A considerable portion of land has also been reclaimed on the Flintshire side of the estuary, though not by the proprietors of the Dee Company; and it is believed that the aggregate amount which has from first to last been gained from the sea is about 7000 acres. Now it is well authenticated, that previous to the commencement of the land-making operations on that river, there was a depth of not less than a fathom at low water of spring tides up as far as Burtonhead, and that there was an anchorage for vessels of the largest size opposite to Parkgate, the positions of which places are marked on the plan. But when the writer surveyed the Dee in 1838, the depth of 6 feet was not found for more than 6 miles below Burtonhead, the low-water features of the estuary having been forced to that extent further seawards by the extensive reclamation of land in the upper part of the estuary, and the consequent diminution of the tidal scour. It cannot, we think, be disputed, that the effect of the works executed on the River Dee, whatever may have been the anticipations of their projectors, has been to shut out the sea, and form land at the expense of the navigation. They are designed, in fact, in direct opposition to the general principle laid down in the present treatise, which provides for the admission of the greatest possible quantity of tidal water.

It seems also equally clear that an increase of tidal water must inevitably attend the execution of such works as we have proposed; but in proof of this assumption, and in contrast to the case of the Dee, it may be well for the reader's information to cite examples which have occurred in practice. Proceeding on actual calculations of comparative sections of the River Tay before and after the operations, the writer found that by the lowering of the low-water line, consequent on the improved state of the river, an additional quantity of sea water, amounting on an average to not less than 1,000,000 cubic yards, or 760,560 tons, is *during every tide* propelled into and again withdrawn from that part of the river which lies above Newburgh. This quantity is equal to two hours' discharge of the Tay in its ordinary state; and it therefore follows that the additional tidal discharge for one year is equal to two months' constant ordinary flow of the River Tay. In the same way it was found by

¹ *Great Britain Coasting Pilot*, by Captain Greenville Collins, hydrographer in ordinary to the King's most excellent Majesty, London, 1767; *Reports to the Admiralty*, by Captain Washington; *Report of Tidal Harbour Commissioners*; *Report* by Messrs Stevenson, 1839.

Rivers. calculation that the additional amount of tidal water admitted every tide into the Lune above Heaton, in consequence of the operations, was 736,278 cubic yards.¹ To estimate truly the beneficial effects of these important changes on the scouring power of the Tay and the Lune, it must be kept in view, that in both cases the increased volume of tidal water, being obtained by the enlargement of the *low-water channel*, operates during *every tide*, and thus may be held to produce the *maximum* amount of benefit; for it is obvious that a cubic yard of low-water area, gained in the low-water channel, and filled by every tide, is very much more valuable than a similar amount of space gained at or near high-water of spring tides, which is filled only at remote intervals.

Depression of low-water line apt to mislead.

The tendency, then, of the whole system of works recommended in this treatise is to lower the low-water line, and to admit an increased amount of tidal water to act on the low-water channel. But the depression of the low-water line, particularly when the river is confined by walls in the lower part of an estuary, conveys the impression that a great rise has taken place in the level of the adjoining sand-banks, and it has consequently been thought that the erection of river walls is inconsistent with the principles of non-exclusion of tide-water which we have recommended; but we are enabled to show that this is not the case. In its natural state, the channel of such an estuary as the Lune or the Ribble, as already explained in section iv., is subject to constant change of position. The writer has seen many acres of marsh or grass land in such estuaries carried off by the waves, and the solid matter of which they were composed scattered over the shores and sand-banks. Now, the effect of fixing the channel by means of walls, in the manner which has been recommended, is to form one permanent navigable track; and the banks on either side, being no longer subject to the periodical inroads of the river or tides, gradually rise in elevation until they are capable of producing vegetation, and ultimately become what are termed marsh

lands. When a river channel has been thus fixed and confined by walls, it has been ascertained by repeated observation that the tidal water comes up the channel in a comparatively pure state, instead of being loaded with particles abraded from the sand-banks and marshes. It has also been found that the process of deposit at the sides of an estuary so improved goes on very slowly after it has reached a certain stage; for the materials deposited on the upper parts of the banks are, as afterwards more particularly described, exceedingly fine, and are carried only by the highest tides, which seldom reach those elevated portions of the shores. From all these considerations we infer that the effect of river-walls upon an estuary is to prevent the constant disturbance of the materials of which the banks are composed, but not to occasion additional accumulations.

Rivers.

The writer had an opportunity, in the case of the Lune, As tested of testing by actual measurement in how far the raising of in the the banks, caused by the erection of walls, was due merely Lune. to a new disposition of the materials which originally filled the bed of the estuary, or to additional foreign matters deposited in consequence of the operations; and the following results are instructive, being, it is believed, the only observations that have been made to determine the state of the sand-banks of an estuary after the river has been improved, as compared with their former condition.

The rubble walls and other works constructed on the Lune caused, as might have been expected, a very considerable alteration in the position and form of the sand-banks in the estuary; and this alteration, in connection with the depression of from 2 to 3 feet in the low-water level of the river, was apt to lead a casual observer to suppose that a great accumulation of sand had taken place, and consequently that a corresponding amount of back-water had been excluded. The writer was authorized by the Admiralty to make such observations as were neces-

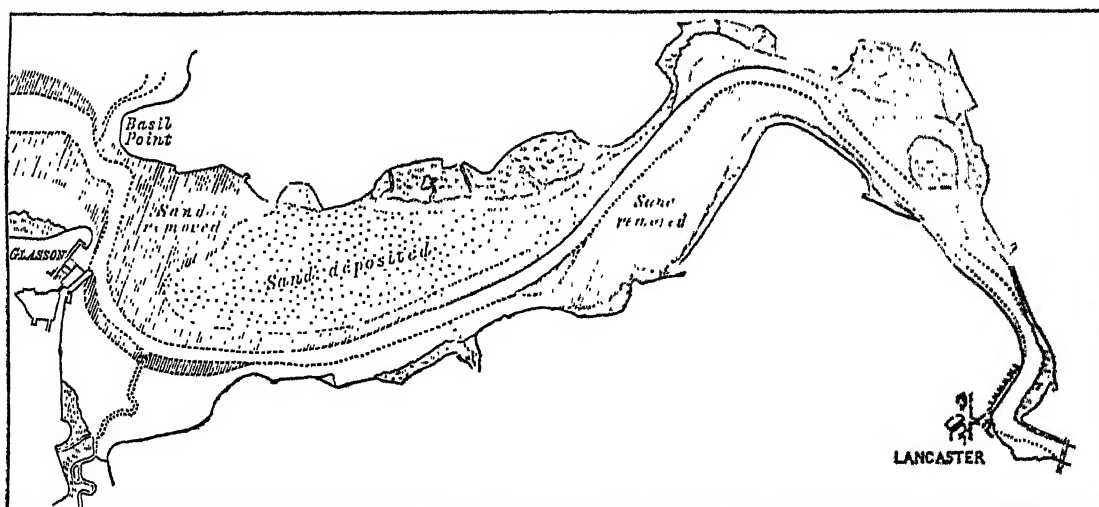

Fig. 24.

sary to determine the true state of the case. Figure 24 represents the changes that were produced by the works. Over the whole area which is represented as covered by sand a deposit had taken place, the banks being higher than formerly; whereas the whole area included in hatched lines had been scoured, the banks having been lowered. A

careful calculation was made, founded on numerous sections taken in 1838, before the works commenced, and in 1851, after their completion. The result of this investigation was, that after the completion of the works, the amount of deposit on the space shown as sand in the cut was 3,070,146 cubic yards; while the amount of scour on the

¹ The mere cubic contents dredged from a ford or shoal often form no measure of the gain of tidal water due to the operations, because the removal of such an obstruction has the effect of lowering the low-water line for a considerable distance up the river, the extent to which the influence of the works extends depending on the amount of fall; and the whole of the wedge-shaped space included between the old and new low-water lines is a clear gain of tide-water, and the cubic contents of this space generally greatly exceed the cubic quantity of materials removed from the ford by dredging.

Rivers. space shown by hatched lines was 2,810,449 cubic yards; giving an excess of deposit of 259,697 cubic yards. But the amount stated as having been scoured does not include what has been taken away below Glasson and Basil points; and which has doubtless been deposited in the bank above. The survey of 1838 did not afford data for ascertaining the amount of what had been scoured from below Glasson with sufficient accuracy to admit of its being included in the foregoing calculations. But an amount of scouring was ascertained to have actually occurred at that place, which was amply sufficient to counterbalance the surplus of 259,697 cubic yards of deposit, as given in the above statement.

Such a result, we think, may indeed be expected; for it is difficult to conceive in what way parallel walls formed in an estuary can operate either in bringing down additional alluvial matters from the river above, or in bringing up additional detritus from without the bar.

Holding these views, and supported by the actual observations made in the case of the Lune, we therefore conclude—1st, That works executed in accordance with the principles laid down do not necessarily produce additional accumulation of matter, but *simply alter the disposition of the existing materials of which the bed of the estuary was originally composed.* 2d, By deepening the navigable track they admit of a large accession of water to act upon the low-water channel during all tides, and at the most favourable period of the tide. 3d, That the depth of water on such bars as are produced by the action of the waves may be maintained, and even increased, by means of the works which have been described as applicable to the intermediate or tidal compartments of rivers.

Size of particles transported proportional to velocity of stream.

While treating of deposits, this is probably the proper place to observe, that the size of detrital particles which can be carried by a current depends on the velocity of the stream, the nature of the bottom along which the detritus is moved, as well as the shape of the particles of which the detritus itself is composed, and is altogether a subject so dependent on special circumstances, that there is great difficulty in laying down rules which can be generally applicable. The following are the results of experiments made by Bossut, Dubuat, and others, on the size of detrital particles which streams flowing with different velocities are said to be capable of carrying:—

3 in. per sec.	=0.170	mile per hour will just begin to work on fine clay.
6 " "	=0.340	do., will lift fine sand.
8 " "	=0.454	do., will lift sand as coarse as linseed.
12 " "	=0.681	do., will sweep along fine gravel.
24 " "	=1.363	do., will roll along rounded pebbles 1 inch in diameter.
3 ft. "	=2.045	do., will sweep along slippery angular stones of the size of an egg.

The only recent experiments made on this subject are those of Mr T. Login, C.E., given in the *Proceedings of the Royal Society of Edinburgh*, vol. iii., p. 475, which were made with a stream seldom exceeding half an inch in depth; and are as follows:—

Nature of Materials.	Rate of sinking in water.	Current required to move.	
	Feet per minute.	Feet per minute.	Mile per hour.
Brick-clay when mixed with water, and allowed to settle for half an hour.....	566	15	1.70
Fresh-water sand.....	10	40	4.54
Sea sand.....	11.707	66.22	7.52
Rounded pebbles about the size of peas.....	60	120	1.37
Vegetable soil.....	...	50	56

Brick-clay in its natural state was not moved by a current of 128 feet per minute, or 1.45 mile per hour.

Rivers. We give these results as they have been stated by their authors; at the same time it is necessary to say that, for the reason above mentioned, we consider their application in practice to be very uncertain. Regarding the subject in a general point of view, however, certain laws as to the transmission and deposition of detritus will be found applicable to certain situations. On this subject Sir H. De la Beche says:—"Where the velocity of a river is sufficient to produce attrition of the substances which it has either torn up, collected by undermining its banks, or which have fallen into it, they gradually become more easy of transport, and would, if the force of the current continued always the same, be forced forward until the river delivered itself into the sea; but as the velocity of a current greatly depends on the fall of the river, the transport is regulated by the inclination of the river's bed. Now it is well known that this inclination varies materially even in the same river; so that it may be able to carry detritus to one situation, but may be unable to transport it further under ordinary circumstances, in consequence of diminished velocity. As a general fact, it may be fairly stated that rivers, where their courses are short and rapid, bear down pebbles to the seas near them, as in the case of the Maritime Alps, &c.; but that where their courses are long, and change from rapid to slow, they deposit the pebbles where the force of the stream diminishes, and finally transport mere sand or mud to their mouths, as is the case with the Rhone, Po, Danube, Ganges, &c."

In rivers, lightest matters found next the sea.

This holds true in the case of such rivers as those to which Sir H. De la Beche refers; but it will be found that the case is exactly reversed in tidal estuaries. There the heavier sands and deposits are found at the mouth of the estuary, and the particles are lighter as we recede inwards. The writer has tested this on several occasions, more particularly in the Dee, the Ribble, the Lune, the Wear, the Forth, and the Tay, by agitating equal quantities of sand and deposit (taken from different parts of the tidal estuary) in equal quantities of water, and observing the time which elapsed in each case before the materials were deposited and the water assumed a state of purity. The result of these observations proved that the sand of outer or seaward banks was composed of large particles, which were held in suspension only a few seconds, and that in the inner parts of the estuary the deposit decreased in weight, and that *generally* it decreased from low to high water, where the silt was exceedingly fine, and remained in suspension in some cases even for hours after the agitation of the water. The following statement by Mr William Bald of experiments made on materials taken from different parts of the bed of the Clyde, shows the variety of materials found in the same stream, and is a valuable record of the weight of the deposits which form the beds of our tidal rivers:²—

DEPOSITS.	Lbs. to cubic feet.	No. of cubic ft. to the Ton.
Fine sand and a few pebbles laid in the box, loose, not pressed, nearly dry.....	87	26
Do. do. pressed.....	92	24
Mud at White Inch, dry, and firmly packed; contained very fine sand and mica.....	97	23
Wet mud, rather compact and firm, well pressed into the box.....	115	19
Wet, fine sharp gravel, well pressed.....	124	18
Wet running mud.....	122½	18.1
Sharp dry sand deposit in harbour.....	92	24.3
Port-Glasgow Bank (sand) wet, pressed into a box	120½	18.6
Sand opposite Erskine House, wet, pressed.....	116	19.3
Alluvial earth, pressed.....	93	24
" " loose.....	67	33

The writer of this article found the gravel of the Tay to be 18 feet to the ton.

Rivers.
Quantity
of matters
in suspen-
sion.

The quantity of solid matter carried or held in suspension by rivers has also been made the subject of observation; but the different observers whose remarks have come under our notice have stated their results in different ways, some giving the *weight* and others the *bulk* of detritus. But assuming 18 cubic feet of solid matter to weigh a ton, we think the following table presents a fair view of the cubic measure of solid matter, and the ratios of volume and weight in each case. In submitting this table, we must observe that the discrepancies in the statements are so great, that further observations are necessary before any satisfactory conclusion can be arrived at; but we give the results as they have been stated by their respective authorities:—

Name of River.	Cubic inches of solid matter in every cubic yard of water.	Ratios of volume of solid matter to volume of water.	Ratios of weight of solid matter to weight of water.
Mississippi, mean...	15.5	$\frac{1}{1000}$	$\frac{1}{1000}$
Irrawaddy, in flood..	11.71	$\frac{1}{1000}$	$\frac{1}{1000}$
Do., ordinary state	4.1	$\frac{1}{1000}$	$\frac{1}{1000}$
Rhine, in flood	1.87	$\frac{1}{1000}$	$\frac{1}{1000}$
Do., ordinary state	1.13	$\frac{1}{1000}$	$\frac{1}{1000}$
Do., mean	1.5	$\frac{1}{1000}$	$\frac{1}{1000}$
Mersey, flood-tide...	29	$\frac{1}{1000}$	$\frac{1}{1000}$
Do., ebb-tide.....	33	$\frac{1}{1000}$	$\frac{1}{1000}$

From this table it will be seen that the Rhine, as compared to the others, is exceedingly pure; while the waters of the Mersey, on the other hand, hold in suspension a very large amount. It must be kept in view, however, that the source from whence the sedimentary matter in the Mersey is derived is very different from any of the other cases mentioned in the table. The main part of the solid matter in suspension in the Mersey, and indeed in all our tidal rivers, is sand, stirred up by the flowing tide, which is deposited again during the ebb-tide. The sedimentary matters in such rivers as the Mississippi or the Irrawaddy, on the other hand, are borne down from the low tracts of alluvial country through which it flows, and form a constant and consequently increasing deposit at the mouth of the river.¹

Formation
of deltas.

In all cases where the tidal currents across the mouths of such rivers are languid or altogether absent, as in the Mississippi, the Nile, the Danube, and other continental rivers, the deposits brought down are not carried away, but form deltas, which collect with greater or less rapidity in proportion to the quantity of material brought down and the depth of water in which it is deposited. Mr Ellet computes the delta of the Mississippi at 40,000 square miles in extent, its average length from north to south being 500 miles. Assuming the sedimentary matter brought down at $\frac{1}{1000}$ th of the volume of water, and the discharge of the river at 21,000,000,000 cubic feet per annum, he estimates that this vast accretion of deposited stuff must have formed at an average rate of 1 mile in 99 years, giving a period for its entire formation of something like 45,000 years! Sir H. De la Beche has, however, with reason, suggested that deltas would increase most rapidly at the first period of their formation, on account of the greater declivity of the river, and the

supposition that the detritus from the interior would become gradually less, from the equalization of levels and the fewer asperities that agents have to act on; and thus it seems impossible to calculate from the present rate of accretion the time which the whole mass has taken to accumulate.

In concluding this treatise, we have to point out in what way, and to what extent, river improvements conducted on the principles advocated benefit adjoining property; for it is obviously highly important if the two objects of *river* and *land* improvement can be carried on simultaneously, and we think that to a certain extent this is perfectly practicable. The attempts of proprietors to protect the foreshores of their lands from the encroachments of rivers in tidal estuaries are often attended with great expense; and if those efforts prove for some time effectual in warding off the approach of the channel, the land speedily takes on vegetation, and is fit for pasture. But the tenure by which such property is held is very slight; and the spot which to-day affords grazing for cattle may in a few tides become the navigable channel of the river. Now, it is obvious that the perfect protection from such encroachments afforded by the training and guiding of the low-water channel by longitudinal walls, adds materially to the value of the adjoining property; for not only is the land beyond high-water mark completely protected from encroachment, but the marsh lands bordering the estuary become in fact *perpetual property*, and not an ever-changing benefit held for one year and probably lost the next. Marsh lands so protected from waste are still, it is true, liable to be flooded by high tides, a circumstance, however, which is considered by some persons not injurious, but rather beneficial, for marsh pasture lands.

Adjoining
property
benefited
by river
improve-
ments.

The process of reclamation in all such cases goes on very slowly after it has reached a certain stage, because, as the banks rise, they are more seldom covered by the tide, and the materials deposited on the inner and higher parts of the banks are, as already stated, exceedingly fine, and are carried only by the highest tides, which seldom reach them. Mr Park has found on the Ribble that the first indications of vegetation appear when the banks are elevated 12 ft. et above the ordnance datum-line, which is the mean level of the sea. This height corresponds at the Ribble to about the level of high-water of neap tides. Mr Gordon² also found, that in the Norfolk estuary "the samphire began to settle on the sands, which the neap tides just cover," and that "grass began to grow about one foot above the samphire level." Such marsh lands, if left unprotected, must remain for ever liable to be covered during high floods or tides, and therefore cannot be said to be available as arable lands, without the erection of considerable works for the purpose of protecting them from floods, and providing for their effectual drainage. As the erection of such works, however, forms no part of river improvement, we allude to them in this place only for the purpose of remarking, that in all cases they should be erected with caution. There are situations in which the erection of embankments for protecting land may be injurious to the interests of navigation; there are others in which such works, if judiciously laid out, may be harmless; but their

Level of
vegetation
on marsh
lands.

¹ Mr Ellet says that the sedimentary matter transported by the Mississippi forms $\frac{1}{1000}$ th part of the volume discharged by the river. (Ellet, *On the Ohio and Mississippi*.)—Mr T. Login, C.E., in Pegu, states in a paper on the Delta of the Irrawaddy, read before the Royal Society of Edinburgh, session 1857, that the waters of the Irrawaddy contained $\frac{1}{1000}$ th part of their weight of sediment during floods, and $\frac{1}{1000}$ th part of their weight when the river was in a low state, and gives the mean deposit at 8 inches per cubic yard.—Mr Leonard Horner found that the water of the Rhine at Bonn contained from $\frac{1}{1000}$ th part of its weight during floods to $\frac{1}{1000}$ th part of its weight in a low state. (*Arcana of Science and Art*, 1835.)—Captain Denham found that the tidal water of the Mersey contained 29 cubic inches of solid matter in every cubic yard during flood-tide, and 33 cubic inches in every cubic yard during ebb-tide. (*Observations on the Mersey*, by Captain H. M. Denham, R.N., Liverpool, 1840.)—Mr Lyell says:—"Hartsaeker computed the Rhine to contain, when most flooded, 1 part in 100 of mud in suspension. By several observations of Sir George Staunton, it appeared that the water of the Yellow River in China contained earthy matter in the proportion of 1 to 200. Manroli, the celebrated Italian hydrographer, conceived the average proportion of sediment in all running water to be $\frac{1}{1000}$ th. Some writers, on the contrary, as De Maillet, have declared the most turbid waters to contain far less sediment than any of the above estimates would import; and there is so much contradiction and inconsistency in the facts and speculations hitherto promulgated on the subject, that we must wait for additional experiments before we can form any opinion on the subject." (*Principles of Geology*, by Charles Lyell, F.R.S., London, 1830, vol. i., p. 247.)

² *Report on Norfolk Estuary*, by L. D. B. Gordon, C.E., Glasgow, 1856.

Rivers. effect in any case can only be determined by a careful consideration of the special circumstances of the locality in which they are erected. We know many cases where the interests of navigation have been sacrificed by unwarrantable encroachment; and, on the other hand, instances are not wanting where even important works have been embarrassed and crippled by an over-cautious regard to the principle of *non-encroachment* on the high-water line.

With reference more particularly to the operations of landowners, it is notorious that in many cases attempts to reclaim or protect property have led to serious and costly legal proceedings between landowners and the local conservators of navigations; and this we are sensible has in some instances arisen from a feeling, on the part of the landowners, that their operations could not be regarded as prejudicial. The local conservators, on the other hand, have generally no means of knowing what the ultimate intentions of the landowners are until their operations have proceeded so far as to render it impossible, if the interest of navigation require it, to stop or to remove the works without considerable loss. A difference of opinion has thus been raised, which has too often ended in an expensive lawsuit. We have long held the opinion that it would in many, if not in all, of our estuaries, be most desirable to have a line of conservation marked out by the Admiralty (without whose authority no encroachment can be made within high-water mark) for the regulation of all works for the protection of land. Were such a line defined, the landowners could then with confidence, and without risk of challenge, enter on such works within the line of conservation as they considered necessary for the protection of their property, and a source of much difference of opinion and expensive litigation would be at once removed. We had hoped that the Tidal Harbour Commission, who have been enabled, through the exertions of Captain Washington, the hydrographer of the Admiralty, who was one of the commission,

to give in their printed reports so valuable a fund of information on our tidal harbours, would have terminated their labours by pointing out and recommending some such system as we have suggested of defining lines of conservation for all the important rivers and estuaries of the country. It is obvious, however, that were such a duty to be performed, it must be committed to a duly qualified commission, acting most naturally under the Admiralty, and so composed that the protection of navigation, and the interests of landowners or trustees for public works, should be fully represented, the whole of its members being actuated by one common desire to do what is best for the community at large.

The following is a statement of ratios between the discharges of certain rivers during low-water and when in flood; but it must be kept in view, as stated in treating of the formulæ for calculating the discharge, that its determination is a difficult problem; so that the results stated with reference to the discharge of different rivers must be received with this caution as to their accuracy.

	Mean Discharge. Cubic ft. per min.	Flood.	
Clyde.....	48,000	194,000	1 to 4.0
Conon.....	7,969	216,589	1 „ 27.2
Earn.....	54,000	215,600	1 „ 3.9
Ganges.....	12,420,000	29,652,480	1 „ 2.4
Irrawaddy.....	4,500,000	45,000,000	1 „ 10.0
Mississippi.....	39,954,000	76,800,000	1 „ 1.9
Nile.....	1,386,000	13,200,000	1 „ 9.5
Tay.....	218,000	753,740	1 „ 3.4
Thames.....	80,220	475,000	1 „ 5.9

The high ratio on the Conon may be due to the steepness of its bed, and the absence of any natural lake or reservoir on its course to act as a regulator.

The quantities in the following table represent the discharges of the rivers in their ordinary state.

Physical Characteristics of Rivers.

(D. S.—N.)

NAVIGATION LAWS, THE, of which some notice has been given under the articles COMMERCE and EX-LAND, and which were considered obnoxious to the interests of commercial enterprise, were in effect repealed in 1854. An act to admit foreign ships to the coasting trade of this country (17th Vict., cap. 5) was passed March 23, 1854; and an act to amend and consolidate the acts relating to merchant shipping (17th and 18th Vict., cap. 104) on the 10th August 1854. The latter act received some amendment, particularly with regard to the erection and maintenance of colonial lighthouses (18th and 19th Vict., cap. 91) in 1855.

NAVIGATOR'S ISLANDS, or SAXOAN ISLANDS, a group in the Pacific, lying to the N.E. of the Friendly Islands, between S. Lat. 13. 30. and 14. 30., and W. Long. 168. and 173. They are eight in number, and three of them are of considerable size. The largest of the group is Savaii, which is upwards of 200 miles in circuit, and the principal others are Maoota, Pala, and Oyalava. They are for the most part mountainous and of volcanic formation. The soil is very rich and fertile, and the mountains are thickly covered with wood to their very summits. The trees are chiefly evergreens, and are remarkable for the beauty and variety of their appearance. Palms, cocoa-nut trees, breadfruit trees, banyans, sugar-canes, pine-apples, potatoes, coffee, yams, and tobacco are among the productions of these

islands. The climate is variable, and heavy rains fall during the winter. No indigenous quadrupeds are found; but horses, cattle, and swine, which have been introduced from other places, thrive well and increase largely. Fowls are numerous, and the surrounding parts of the ocean abound in fish. The inhabitants are superior in appearance to most of the tribes of the South Sea Islands. They are stout, well-proportioned, and of a dark-brown complexion, and the men are in general better looking than the women. In character, they are generally good-natured, hospitable, and affectionate, and they show great respect for the aged. They are intelligent, and display considerable ingenuity in making their canoes and houses; but they are indolent, fond of pleasure, covetous, and deceitful. Their language is smooth and liquid, and in it alone of Polynesian tongues the sibilant sound occurs. The Navigator's Islands were first visited by missionaries in 1830 from Otaheite; and since 1836 missionaries have been sent out directly from Europe, by whose means a great number of the inhabitants have been converted to Christianity. They are also beginning to pursue the employments of trade, and to learn the use of money. Cocoa-nut oil is the principal article of export, and the imports are cotton, calicoes, fire-arms, ammunition, &c., supplied chiefly by American whalers. The whole area of the islands is 2650 square miles; and the estimates of the population vary from 50,000 to 160,000.

N A V Y.

Navy.

AN insular empire, like that of the united kingdom of Great Britain and Ireland, which is so much indebted, and always must be, for that power, prosperity, and renown which she enjoys, to the glorious deeds of her navy, cannot but take a peculiar degree of interest in every thing that concerns it. This vast machine, indeed, has at all times been the pride and boast of Great Britain, the terror of its enemies, and the admiration of the world. It is under the impression of its vast importance that we have been induced to give, under their proper heads, such details of the civil and military branches of the naval departments as may afford, without entering into too minute details, a comprehensive sketch of this great national bulwark, of which it is now proposed to take a general view.

The term NAVY is generally intended to express all ships of commerce as well as those of war, the mercantile as well as the military marine; but the observations contained in the present article are meant to relate only to the latter, excepting that, in speaking of the progressive enlargement of ships, and improvements in naval architecture, the remarks may sometimes equally apply to ships of commerce and of war.

NAVY composed of *MATERIEL* and *PERSONNEL*.

The composition of a navy may be considered under the two distinct heads into which it naturally divides itself, and under which the French generally distinguish an army, the *matériel*, and the *personnel*; the former embracing every thing that appertains to the ships, their capacity, construction, armament, and equipment; the latter all that concerns the rank, the appointment, the various duties, &c. of the officers, seamen, and marines.

I.—*MATERIEL* OF THE NAVY.

History.

It would occupy too large a space to give even a short sketch of the origin and the progress of naval architecture, from a bundle of branches, or the hollow trunk of a tree—the rude raft and the frail canoe—to the more perfect coracle, or the wicker-boats of the ancient Britons, covered with hides. For many centuries after the expulsion of the Romans from, or their abandonment of, the British Islands, very little progress appears to have been made by us in the art of navigation or ship building: the natives would appear, for many centuries afterwards, to have acted merely on the defensive against naval invasions.

“The whole of our naval history,” say the commissioners for revising the civil affairs of the navy, “may be divided into three periods; the *first* comprehending all that preceded the reign of Henry VIII.; the *second* ending with the restoration of Charles II.; and the *third* coming down from the Restoration to the present day.”

First period.

To what size, and to what extent, the amount of the English ships or vessels were carried, which supported so many contests with the invading Danes in the ninth century, our naval history has not preserved any record. We are told, however, that Alfred increased the size of his galleys, and that some of them were capable of rowing thirty pair of oars. These galleys were chiefly employed in clearing the Channel of the nests of pirates by which it was infested. It is also said, as a proof of his attention to naval matters, that, under his auspices, one Ochter under-

took a voyage into the arctic regions, made a survey of the coasts of Lapland and Norway, and brought to Alfred an account of the mode pursued by the inhabitants of those countries to catch whales. It is, moreover, on record, that his two sons, Edward and Athelstan, fought many bloody actions with the Danes, in which several kings and chiefs were slain; and that Edgar had from three to five thousand ships, divided into three fleets, stationed on three several parts of the coast, with which, passing from one fleet or squadron to the other, he circumnavigated the island; that after this he called himself “Monarch of all Albion, and Sovereign over all the adjacent Isles.” Some notion, however, may be formed of the size of the vessels which composed his fleets, from the imposition of a land-tax, which required certain proprietors to furnish a stout galley of three rows of oars, to protect the coast from the Danish pirates. The more effectually to check these marauders, and protect the coasts of the kingdom, William the Conqueror, in 1066, established the Cinque Ports, and gave them certain privileges, on condition of their furnishing fifty-two ships, with twenty-four men in each, for fifteen days, in cases of emergency. We should not, perhaps, be far amiss in dating the period of our naval architecture from the Conquest. “The Normans,” says Sir Walter Raleigh, “grew better shipwrights than either the Danes or Saxons, and made the last conquest of this land; a land which can never be conquered whilst the kings thereof keep the dominion of the seas.” But Raleigh does not describe what the ships were which the Normans taught us to build; nor can it now be known in what kind of vessels William transported his army across the Channel, or what was the description of the hundred large ships and fifty galleys of which the naval armament of Richard I. consisted on his expedition to the Holy Land. We are told, however, that having increased his fleet at Cyprus to two hundred and fifty ships and sixty galleys, he fell in with a ship belonging to the Saracens, of such an extraordinary size that she was defended by 1500 men, all of whom, with the exception of 200, Richard, after taking possession of her, ordered to be thrown overboard and drowned.

There can be no doubt that the nations of the Mediterranean, particularly the Genoese and Venetians, introduced many improvements as to the capacity and stability of their ships, in consequence of the crusades, and the demands for warlike stores and provisions which such vast and ill-provided armies necessarily created; but these improvements would seem not to have reached, or, at least, to have made but a tardy progress in, Great Britain. King John, it is true, stoutly claimed for England the sovereignty of the sea, and decreed that all ships belonging to foreign nations, the masters of which should refuse to strike to the British flag, should be seized and deemed good and lawful prize. And this monarch is said to have fitted out no less than five hundred sail of ships, under the Earl of Salisbury, in the year 1213, against a fleet of three times that number, prepared by Philip of France for the invasion of England; of which the English took three hundred sail, and drove a hundred on shore, Philip being under the necessity of destroying the remainder, to prevent their falling also into the hands of the English. Of the kinds of ships of which his fleet consisted, some notion may be formed by the account that is related of an action fought in the following reign with the French, who, with “eighty stout ships,” threatened the coast of Kent. This fleet being discovered by Hubert de Burgh, governor of Dover Castle, he put to sea with forty English ships, and having got to

Matériel. the windward of the enemy, and run down many of the smaller ships, he closed with the rest, and threw on board them a quantity of quicklime, which blinded them so effectually that all their ships were either taken or sunk.

Whatever the size and the armaments of our ships were, the empire of the sea was bravely maintained by the Edwards and the Henrys in many a gallant and glorious sea-fight with the fleets of France, against which they were generally opposed with inferior numbers. The temper of the times, and the public feeling, were strongly exemplified in the reign of Edward I. by the following circumstance: An English sailor was killed in a Norman port, in consequence of which a war commenced, and the two nations agreed to decide the dispute on a certain day, with the whole of their respective naval forces. The spot of battle was to be the middle of the Channel, marked out by anchoring there an empty ship. The two fleets met on the 14th April 1293; the English obtained the victory, and carried off above two hundred and fifty sail.

In an action with the French fleet off the harbour of Sluys, Edward III. is said to have slain 30,000 of the enemy, and to have taken two hundred great ships, "in one of which only, there were four hundred dead bodies." This is no doubt an exaggeration. The same monarch, at the siege of Calais, is stated to have blockaded that port with seven hundred and thirty sail, having on board 14,956 mariners; twenty-five only of which were of the royal navy, bearing four hundred and nineteen mariners, or about seventeen men each. In various other sea actions did this great sovereign nobly support the honour of the British flag. But though we then, and ever after, claimed the "dominion of the seas," that dominion, says Raleigh, "was never absolute until the time of Henry the Eighth." It was a maxim of this great statesman, that "whosoever commands the sea, commands the trade of the world; whosoever commands the trade, commands the riches of the world, and consequently the world itself."

The reign of Henry V., however, was most glorious in maintaining the naval superiority over the fleets of France. From a letter of this sovereign to his lord chancellor, dated 12th August 1417, discovered by Samuel Lyons among the records in the Tower, and of which the following is a copy, it would appear that there was something like an established royal navy in his reign, independently of the shipping furnished by the Cinque Ports and the merchants, for the king's own use, on occasion of any particular expedition. The letter appears to have been written nine days after the surrender of the castle of Touque in Normandy, from whence it is dated.

*"Au révérend pere en Dieu l'Evesque de Duresme nre
Chancellor d'Angleterre.*

"Worshipful fader yn God We sende you closed within this letter a cedula conteynng the names of certain Maistres for owr owne grete Shippes Carrakes Barges and Ballyngers to the whiche Maistres We have granted annuities such as is appointed upon eche of hem in the same Cedula to take yerely of owre grante while that us lust at owr Exchequer of Westm^r. at the termes of Michelmasse and Ester by even porcions. Wherefore We wol and charge yow that unto eche of the said Maistres ye do make under owr grete seel beyng in yowre warde owr letters patentes severales in due forme after th'effect and pourport of owr said grante. Yeven under owr signet atte owr Castle of Touque the xij. day of August."

Matériel.

The remainder, to the masters of which pensions were thus granted, consist of seventeen "niefs, barges, and ballyngers," some with three, and others two mariners only. But history informs us, that about this time Henry embarked an army of 25,000 men at Dover on board of 1500 sail of ships, two of which carried purple sails, embroidered with the arms of England and France; one styled the King's Chamber, the other his Saloon, as typical of his keeping his court at sea, which he considered as a part of his dominions. Still we are left in the dark as to the real dimensions of his ships, and the nature of their armament; they were probably used only as transports for his army. It would appear, however, from a very curious poem, written in the early part of the reign of King Henry VI. that the navy of his predecessor was considerable, but that, by neglect, it was then reduced to the same state in which it had been during the preceding reigns. The poem here alluded to is entitled "The English Policie, exhorting all England to keep the Sea, and namely the Narrow Sea; showing what profit cometh thereof, and also what worship and salvation to England and to all Englishmen;" and is printed in the first volume of Hackluyt's Collection of Voyages. It was evidently written before the year 1438, when the Emperor Sigismond died, as appears by the following passage in the prologue:

For Sigismond, the great Emperour,
Which yet liveth, when he was in this land,
With King Henry the Fifth, Prince of Honour,
Here much glory, as him thought, he found
A mightie land, which had take in hand
To werre with France, and make mortalitie,
And ever well kept round about the sea.

The part of the poem which alludes to the navy of King Henry V. is entitled "Another incident of keeping the Sea, in the time of marvellous werriour and victorious Prince, King Henrie the Fifth, and of his great Shippes."

The following are the most remarkable passages:

And if I should conclude all by the King
Henrie the Fift, what was his purposing,
Whan at Hampton he made the great dromons,
Which passed other great ships of the Commons;
The *Trinitie*, the *Grace de Dieu*, the *Holy Ghost*,
And other moe, which as now be lost.
What hope ye was the Kings great intent
Of thoo shippes, and what in mind he meant:
It was not ellis, but that he cast to bee
Lorde round about environ of the see.
And if he had to this time lived here,
He had been Prince named withouten pere:

Matériel.

His great ships should have been put in preefe,
Unto the ende that he ment of in chiefe.
For doubt it not but that he would have bee
Lord and master about the round see:
And kept it sure, to stoppe our ennemies hence,
And wonne us good, and wisely brought it thence,
That no passage should be without danger,
And his licence on see to move and sterre.

Shortly after the time when this poem must have been written, it appears from the parliament roll (20th Henry VI. 1442), that an armed naval force, consisting only of eight large ships, with smaller vessels to attend them, was to be collected from the ports of London, Bristol, Dartmouth, Hull, Newcastle, Winchelsea, Plymouth, Falmouth, &c.; and, of course, the royal ships of 1417, the names of which are contained in the foregoing schedule, were then either gone to decay or dispersed. We are not to judge of the size of these ships from the few mariners appointed to each. These were merely the ship-keepers, or harbour-duty men, placed on permanent pay, to keep the ships in a condition fit for the sea when wanted.

It is very probable that, until our merchants engaged in the Mediterranean trade, and that the attention of the government was turned, in the reign of Henry VII. (about 1496), to imitate Portugal in making foreign discovery, under the skilful seaman Sebastian Cabot, very little was added to the capacity or the power of British ships of war. It is said, however, that on the accession of Henry VII. to the throne in 1485, he caused his marine, which had been neglected in the preceding reign, to be put into a condition to protect the coasts against all foreign invasions; and that, in the midst of profound peace, he always kept up a fleet ready to act. In his reign was built a ship called the Great Harry, the first on record that deserved the name of a ship of war, if it was not the first exclusively appropriated to the service of the state. This is the same ship which Camden has miscalled the Henry Grace de Dieu, and which was not built till twenty years afterwards, under the reign of Henry VIII. The Great Harry is stated to have cost £14,000, and was burned by accident at Woolwich in the year 1558.

Second
Period.

We now come to that period of our naval history in which England might be truly said to possess a military marine, and of which some curious details have been left us by that extraordinary man of business Mr Pepys, a commissioner of the navy, and afterwards secretary to Charles II., at a time when the king executed in person the office of lord high admiral, and also to James II. until his abdication. His minutes and miscellanies relative to the navy are contained in a great number of manuscript volumes, which are deposited in the Pepysian Library in Magdalene College, Cambridge. From these papers it appears, that in the thirteenth year of Henry VIII. the following were the names and the tonnage of the royal navy:

	Tons.
Henry Grace de Dieu.....	1500
Gabriel Royal.....	650
Mary Rose.....	600
Barbara.....	400
Mary George.....	250
Henry Hampton.....	120
The Great Galley.....	800
Sovereign.....	800
Catherine Forteleza.....	550
John Baptist.....	400
Great Nicholas.....	400
Mary James.....	240
Great Bark.....	250
Less Bark.....	180

Add to these two row-barges of sixty tons each, making,

in the whole, sixteen ships and vessels, measuring 7260 tons.

Matériel.

The Henry Grace de Dieu is stated in all other accounts, and with more probability, to have been only 1000 tons; the rule for ascertaining the measurement of ships being still vague, and liable to great error, was probably much more so at this early period. This ship was built in 1515, at Erith, in the river Thames, to replace the Regent, of the same tonnage, which was burned in August 1512, in action with the French fleet, when carrying the flag of the lord high admiral. There is a drawing in the Pepysian papers of the Henry Grace de Dieu, from which a print in the *Archæologia* has been engraved, and of which a copy has been taken as a frontispiece to C. Derrick's *Memoirs of the Rise and Progress of the Royal Navy*. From these papers it appears that she carried fourteen guns on the lower deck, twelve on the main deck, eighteen on the quarter-deck and poop, eighteen on the lofty fore-castle, and ten in her stern-ports, making altogether seventy-two guns. Her regular establishment of men is said to have consisted of 349 soldiers, 301 mariners, and fifty gunners, making altogether 700 men. Some idea may be formed of the awkwardness in manœuvring ships built on her construction, or similar to her, when it is stated that, on the appearance of the French fleet at St Helens, the Great Harry, built in the former reign, and the first ship built with two decks, had nearly been sunk; and that the Mary Rose, of 600 tons, with 500 or 600 men on board, was actually sunk at Spithead, occasioned, as Raleigh informs us, "by a little sway in casting the ship about, her ports being within sixteen inches of the water." On this occasion the fleets cannonaded each other for two hours; and it is remarked as something extraordinary, that not less than three hundred cannon-shot were fired on both sides in the course of this action. From the prints above mentioned, which agree very closely with the curious painting of Henry crossing the Channel in his fleet to meet Francis on the *Champ de Drap d'Or*, near Calais, and now in the great room where the Society of Antiquaries hold their meetings in Somerset House, it is quite surprising how they could be trusted on the sea at all, their enormous poops and fore-castles making them appear loftier and more awkward than the large Chinese junks, to which, indeed, they bear a strong resemblance. It is worth remarking that, in the year 1840, the position of the Mary Rose, near Spithead, was pointed out to that extraordinary diver Mr Deane, who went down several times, and brought up some beautiful pieces of brass ordnance, as perfect and as fine specimens as any we have at the present day.

Henry VIII. may justly be said to have laid the foundation of the British navy. He established the dock-yards at Deptford, Woolwich, and Portsmouth; he appointed certain commissioners to superintend the civil affairs of the navy, and settled the rank and pay of admirals, vice-admirals, and inferior officers; thus creating a national navy, and raising the officers to a separate and distinct profession. The great officers of the navy then were, the vice-admiral of England, the master of the ordnance, the surveyor of the marine causes, the treasurer, comptroller, general surveyor of the victualling, clerk of the ships, and clerk of the stores. Each of these officers had their particular duties, but they met together at their office on Tower Hill once a week, to consult, and make their reports to the lord high admiral. He also established the fraternity of the Trinity House, for the improvement of navigation and the encouragement of commerce; and built the castles of Deal, Walmer, Sandgate, Hurst Castle, &c. for the protection of his fleet and of the coast.

At the death of Henry VIII. in 1547, the royal navy consisted of about fifty ships and vessels of different sizes, the former from 1000 to 150 tons, and the latter down to

Matériel. twenty tons, making in the whole about 12,000 tons. and manned by about 8000 mariners, soldiers, gunners, &c. In the short reign of his son Edward, little alteration seems to have taken place in the state and condition of the royal navy. But the regulations which had been made in the reign of his father, for the civil government of naval affairs, were revised, arranged, and turned into ordinances, which form the basis of all the subsequent instructions given to the commissioners for the management of the civil affairs of the navy. In the reign of Mary the tonnage of the navy was reduced to about 7000 tons; but her lord high admiral nobly maintained the title assumed by England of Sovereign of the Seas, by compelling Philip of Spain to strike his flag that was flying at the main-top-mast head, though on his way to England to marry Queen Mary, by firing a shot at the Spanish admiral. He also demanded that his whole fleet, consisting of 160 sail, should strike their colours and lower their top-sails, as an homage to the English flag, before he would permit his squadron to salute the Spanish monarch.

The reign of Elizabeth was the proudest period of our naval history, perhaps surpassed by none previously to the Revolution. She not only increased the numerical force of the regular navy, but established many wise regulations for its preservation, and for securing adequate supplies of timber and other naval stores. She placed her naval officers on a more respectable footing, and encouraged foreign trade and geographical discoveries, so that she acquired justly the title of the Restorer of Naval Power, and Sovereign of the Northern Seas. The greatest naval force that had at any previous period been called together was that which was assembled to oppose the Invincible Armada, and which, according to the notes of Mr Secretary Pepys, consisted of 176 ships, with 14,992 men; but these were not all "Shippes Royall," but were partly composed of the contributions of the Cinque Ports and others. The number actually belonging to the navy is variously stated, but they would appear to have been somewhere about forty sail of ships, manned with about 6000 men. At the end of her reign, however, the navy had greatly increased, the list in 1603 consisting of forty-two ships of various descriptions, amounting to 17,000 tons, and manned with 8346 men. Of these, two were of the burden of 1000 tons each, three of 900 tons, and ten from 600 to 800 tons.

James I. was not inattentive to his navy. He warmly patronised Mr Phineas Pett, the most able and scientific shipwright that this country ever boasted, and to whom we undoubtedly owe the first essential improvements in the form and construction of ships. The cumbrous top-works were first got rid of under his superintendence. "In my owne time," says Raleigh, "the shape of our English ships hath been greatly bettered; in extremity we carry our ordnance better than we were wont; we have added crosse pillars in our royall shippes, to strengthen them; we have given longer floors to our shippes than in older times," &c. The young Prince Henry was so fond of naval affairs, that Phineas Pett was ordered by the lord high admiral to build a vessel at Chatham in 1604, with all possible speed, for the young Prince Henry to disport himself in, above London Bridge; the length of her keel was twenty-eight feet, and her breadth twelve feet. In 1610 Pett laid down the largest ship that had hitherto been built. She was named the Prince Royal; her burden was 1400 tons, her keel 114 feet, and she was armed with sixty-four pieces of great ordnance, "being in all respects," says Stowe, "the greatest and goodliest ship that was ever built in England." He adds, "the great workmaster in building this ship was Mr Phineas Pett, gentleman, some time master of arts, of Emanuel College, in Cambridge."

This excellent man, as appears from a manuscript ac-

Matériel count of his life in the British Museum, written by himself, was regarded by the shipwrights of the dock-yards, who had no science themselves, with an eye of jealousy; and a complaint was laid against him before the king, of ignorance in laying off a ship, and of a wasteful expenditure of timber and other matters. The king attended at Woolwich with his court, to inquire in person into the charges brought forward, and, after a painful investigation, pronounced in favour of Mr Pett. One of the charges was, that he had caused the wood to be cut across the grain; but the king observed, that, as it appeared to him, "it was not the wood, but those who had preferred the charges, that were cross-grained."

The state of the navy at the king's death is variously given by different writers; but on this subject the memoranda left by Mr Secretary Pepys are most likely to be correct. From them it appears that, in 1618, certain commissioners were appointed to examine into the state of the navy, and by their report it appears there were then only thirty-nine ships and vessels, whose tonnage amounted to 14,700 tons; but in 1624, on the same authority, the numbers had decreased to thirty-two or thirty-three ships and vessels, but the tonnage increased to about 19,400 tons. The commissioners had, in fact, recommended many of the small craft to be broken up or sold, and more ships of the higher rates to be kept up.

The navy was not neglected in the troublesome reign of Charles I. This unfortunate monarch added upwards of twenty sail to the list, generally of the smaller kind: but one of them, built by Pett, was of a description, both as to form and dimensions, far superior to any that had yet been launched. This ship was the celebrated Sovereign of the Seas, which was launched at Woolwich in 1637. The length of her keel was 128 feet, the main breadth forty-eight feet, and from stem to stern 232 feet. In the description of this ship by Thomas Heywood, she is said to have "bore five lanthorns, the biggest of which would hold ten persons upright; had three flush-decks, a fore-castle, half-deck, quarter-deck, and round-house. Her lower tier had thirty ports for cannon and demi-cannon; middle tier, thirty for culverins and demi-culverins; third tier, twenty-six for other ordnance; fore-castle, twelve; and two half-decks, thirteen or fourteen ports more within board, for murdering pieces; besides ten pieces of chace ordnance forward, and ten right aft, and many loop-holes in the cabins for musquet-shot. She had eleven anchors, one of 4400 pounds weight. She was of the burden of 1637 tons." It appears, however, that she was found, on trial, to be too high for a good serviceable ship in all weathers, and was therefore cut down to a deck less. After this she became an excellent ship, and was in almost all the great actions with the Dutch; she was rebuilt in 1684, when the name was changed to that of Royal Sovereign; and was about to be rebuilt a second time at Chatham in 1696, when she accidentally took fire, and was totally consumed. In this reign the ships of the navy were first classed, or divided into six rates, the first being from 100 to sixty guns, the second from fifty-four to thirty-six, &c.

In 1642 the management of the navy was taken out of the king's hands, and in 1648 Prince Rupert carried away twenty-five ships, none of which ever returned; and such, indeed, was the reduced state of the navy, that at the beginning of Cromwell's usurped government, he had only fourteen ships of war of two decks, and some of these carried only forty guns; but, under the careful management of very able men, in different commissions which he appointed, such vigorous measures were pursued, that, in five years, though engaged within that time in war with the greatest naval power in Europe, the fleet was increased to 150 sail, of which more than a third part had two decks, and many of which were captured from the Dutch, and

Matériel. upwards of 20,000 seamen were employed in the navy. Our military marine was, indeed, raised by Cromwell to a height which it had never before reached; but from which it soon declined under the short and feeble administration of his son.

Though Cromwell found the navy divided into six rates or classes, it was under his government that these ratings were defined and established in the manner nearly in which they now are; and it may also be remarked, that, under his government, the first frigate, called the *Constant Warwick*, was built in England. "She was built," says Mr Pepys, "in 1649, by Mr Peter Pett (son of Phineas), for a privateer for the Earl of Warwick, and was sold by him to the state. Mr Pett took his model of this ship from a French frigate which he had seen in the Thames."

During the first period of our naval history, we know nothing of the nature of the armament of the ships. From the time of Edward III. they might have been armed with cannon, but no mention is made of this being the case. According to Lord Herbert, brass ordnance were first cast in England in the year 1535. They had various names, such as cannon, demi-cannon, culverins, demi-culverins, sakers, mynions, falcons, falconets, &c. What the calibre of each of these was is not accurately known, but the cannon is supposed to have been about sixty-pounders, the demi-cannon thirty-two, the culverin eighteen, falcon two, mynion four, saker five, &c. Many of these pieces, of different calibres, were mounted on the same deck, which must have occasioned great confusion in action in finding for each its proper shot.

Third period.

On the restoration of Charles II. the Duke of York was immediately appointed lord high admiral, and by his advice a committee was named to consider a plan, proposed by himself, for the future regulation of the affairs of the navy, at which the duke himself presided. By the advice and able assistance of Mr Pepys, great progress was speedily made in the reparation and increase of the fleet. The duke remained lord high admiral till 1673, when, in consequence of the test required by parliament, to which he could not submit, he resigned, and that office was in part put in commission, and the rest retained by the king. Prince Rupert was put at the head of this commission, and Mr Pepys appointed secretary to the king in all naval affairs, and of the admiralty; and by his able and judicious management there were in sea-pay, in the year 1679, and in excellent condition, seventy-six ships of the line, all furnished with stores for six months, eight fire-ships, besides a numerous train of ketches, smacks, yachts, &c. with more than 12,000 seamen; and also thirty new ships building, and a good supply of stores in the dock-yards. But this flourishing condition of the navy did not last long. In consequence of the dissipation of the king, and his pecuniary difficulties, he neglected the navy on account of the expenses; the duke was sent abroad, and Mr Pepys to the Tower. A new set of commissioners were appointed, without experience, ability, or industry; and the consequence was, as stated by the commissioners of revision, that "all the wise regulations formed during the administration of the Duke of York were neglected; and such supineness and waste appear to have prevailed, that, at the end of not more than five years, when he was recalled to the office of lord high admiral, only twenty-two ships, none larger than a fourth rate, with two fire-ships, were at sea; those in harbour were quite unfit for service; even the thirty new ships which he had left building had been suffered to fall into a state of great decay, and hardly any stores were found to remain in the dock-yards."

The first act on the duke's return was the re-appointment of Mr Pepys as secretary of the admiralty. Finding the present commissioners unequal to the duties required

of them, he recommended others. Sir Anthony Deane, the most experienced of the shipbuilders then in England, was joined with the new commissioners. To him, it has been said, we owe the first essential improvement in the form and qualities of ships of the line, having taken the model of the *Superbe*, a French ship of seventy-four guns, which anchored at Spithead, and from which he built the *Harwich* in 1664. Others, however, are of opinion that no improvement had at this time been made on the model of the *Sovereign of the Seas* after she was cut down. The new commissioners undertook, in three years, to complete the repair of the fleet, and furnish the dock-yards with a proper supply of stores, on an estimate of £400,000 a year, to be issued in weekly payments; and in two years and a half they finished their task, to the satisfaction of the king and the whole nation; the number of ships repaired and under repair being 108 sail of the line, besides a considerable number of vessels of smaller size. The same year the king abdicated the throne, at which time the list of the navy amounted to 173 sail, containing 101,892 tons, carrying 6930 guns, and 42,000 seamen.

The naval regulations were wisely left unaltered at the Revolution, and the business of the admiralty continued to be carried on chiefly, for some time, under the immediate direction of King William, by Mr Pepys, till the arrival of Admiral Herbert and Captain Russell from the fleet, into whose hands, he says, "he silently let it fall." Upon the general principles of that system, thus established with his aid by the Duke of York, the civil government of our navy has ever since been carried on.

In the second year of King William (1690), no less than thirty ships were ordered to be built, of sixty, seventy, and eighty guns each; and in 1697 the king, in his speech to parliament, stated that the naval force of the kingdom was increased to nearly double what he found it at his accession. It was now partly composed of various classes of French ships which had been captured in the course of the war, amounting in number to more than sixty, and in guns to 2300; the losses by storms and captures on our side being about half the tonnage and half the guns we had acquired. At the commencement of this reign, the navy, as we have stated, consisted of 173 ships, measuring 101,892 tons; at his death, it had been extended to 272 ships, measuring 159,020 tons, being an increase of ninety-nine ships and 57,128 tons, or more than one half both in number and in tonnage.

The accession of Queen Anne was immediately followed by a war with France and Spain, and in the second year of her reign she had the misfortune of losing a vast number of her ships, by one of the most tremendous storms that was ever known; but every energy was used to repair this national calamity. In an address of the House of Lords, in March 1707, it is declared as "a most undoubted maxim, that the honour, security, and wealth of this kingdom does depend upon the protection and encouragement of trade, and the improving and right encouraging its naval strength.....therefore we do in the most earnest manner beseech your majesty, that the sea affairs may always be your first and most peculiar care." In the course of this war were taken or destroyed about fifty ships of war, mounting 3000 cannon; and we lost about half the number. At the death of the queen, in 1714, the list of the navy was reduced in number to 247 ships, measuring 167,219 tons, being an increase in tonnage of 8199 tons.

George I. left the navy pretty nearly in the same state in which he found it. At his death, in 1727, the list consisted of 233 ships, measuring 170,862 tons, being a decrease in number of fourteen, but an increase in tonnage of 3643 tons.

George II. was engaged in a war with Spain in 1739, in consequence of which the size of our ships of the line

Matériel.

Matériel. ordered to be built was considerably increased. In 1744, France declared against us; but on the restoration of peace in 1748, it was found that our naval strength had prodigiously increased. Our loss had been little or nothing, whilst we had taken and destroyed, of the French twenty, and of the Spanish fifteen sail of the line, besides smaller vessels. The war with France of 1755 added considerably to the list, so that, at the king's decease, in 1760, it consisted of 412 ships, measuring 321,104 tons.

In the short war of 1762, George III. added no less than twenty sail of the line to our navy. At the conclusion of the American war in 1782, the list of the navy was increased to 600 sail; and at the signing of the preliminaries in 1783 it amounted to 617 sail, measuring upwards of 500,000 tons; being an increase of 185 ships and 157,000 tons and upwards since the year 1762. At the peace of Amiens the list of the fleet amounted to upwards of 700 sail, of which 144 were of the line. The number taken from the enemy, or destroyed, amounted nearly to 600, of which ninety were of the line, including fifty-gun ships, and upwards of two hundred were frigates; and our loss amounted to about sixty, of which six were of the line and twelve frigates.

The recommencement and long continuance of the revolutionary war, and the glorious successes of our naval actions; the protection required for our extended commerce, of which, in fact, we might be said to enjoy a monopoly, and for the security of our numerous colonies; contributed to raise the British navy to a magnitude to which the accumulated navies of the whole world bore but a small proportion. From 1808 to 1813, there were seldom less than from 100 to 106 sail of the line in commission, and from 130 to 160 frigates, and upwards of 200 sloops, besides bombs, gun-brigs, cutters, schooners, &c. amounting in the whole to about 500 sail of effective ships and vessels; to which may be added 500 more in the ordinary, and as prison, hospital, and receiving ships; making at least 1000 pendants, and measuring from 800,000 to 900,000 tons. The commissioners appointed to inquire into the state and condition of the woods, forests, and land revenues of the crown, state, in their report to parliament, in the year 1792, that, "at the accession of his majesty (Geo. III.) to the throne, the tonnage of the royal navy was 321,104 tons, and at the end of the year 1788 it had risen to no less than 413,467 tons." In 1808 it had amounted to the enormous extent of 800,000 tons, having nearly doubled itself in twenty years.

It must not, however, be supposed that the effective navy consisted of more than half this amount of tonnage. Since the conclusion of the war with France, it would appear that at least one-half of the number of ships then in existence had been sold or broken up as unfit for service; and as, by the list of the navy at the beginning of the year 1821, the number of ships and vessels of every description, in commission, in ordinary, building, repairing, and ordered to be built, had been reduced to 609 sail, we may take the greatest extent of the tonnage at 500,000 tons; but the greater part, if not the whole, of this tonnage was efficient, and in a state of progressive efficiency.

According to the printed list of the 1st January 1821, the 609 sail of ships and vessels appear to be as under:—

1st rates from 120 to 100 guns	23
2d " " 86 " 80 "	16
3d " " 78 " 74 "	90
4th " " 60 " 50 "	20
5th " " 48 " 22 "	107
6th " " 34 " 24 "	40
Sloops " 22 " 10 "	136
Making a total of	432
To which being added, gun-brigs, cutters, schooners, tenders, bombs, troop-ships, store-ships, yachts, &c.,	177
Grand total	609

In the year 1836 the total number of ships of war, including every description mentioned in the above list, amounted to about 560 sail; of which 95 were ships of the line in a state of efficiency for any service, or capable of being speedily put into a fit state for sea; and many of them were of a very superior class to any employed in the war.

In the year 1846 there were 671 ships, including every description; and there are now (1857) on the list of the royal navy 735 ships, exclusive of those appropriated to harbour service, and of the coast-guard cruisers; making a grand total of 888 ships and vessels of all classes.

The increase in the size of our ships of war was unavoidable; France and Spain had increased theirs, and we were compelled, in order to meet them on fair terms, to increase the dimensions of ours; many of theirs were, besides, added to the list of our navy. The following sketch will show the progressive rate at which ships of the first order, or of 100 guns and upwards, were enlarged in their dimensions. In 1677 the first-rates were from 1500 to 1600 tons. In 1720 they were increased to 1800 tons. In 1745 we find them advanced to 2000 tons. During the American war they were raised to 2200 tons. In 1795 the *Ville de Paris*, of 110 guns, measured 2350 tons. In 1804 the *Hibernia*, of 110 guns, was extended to 2500 tons; and in 1808 the *Caledonia*, carrying 120 guns, measured 2616 tons, and here we stopped; but since then the *Nelson*, the *Howe*, the *St Vincent*, the *Britannia*, the *Prince Regent*, the *Royal George*, and the *Neptune*, have been built, all nearly of the same dimensions, and from the same draught—nine such ships as the whole world could not at the time produce. The French had one ship larger than any of these, called the *Commerce de Marseilles*. She was taken by us in Toulon, but broke her back in a gale of wind.

The following were the comparative dimensions of the *Caledonia* and the *Commerce de Marseilles*:—

Ships.	Length of Gun-deck.	Length of Keel.	Extreme Breadth.	Depth of Hold.	Tons.
<i>Caledonia</i>	205 0	170 9	53 8	23 2	2617
<i>Commerce de Marseilles</i> }	208 4	172 0	54 9½	25 6½	2747

The armament of the *Caledonia* was as follows:—On the gun-deck she carried 32 guns, 32-pounders; middle-deck 34 24-pounders, upper-deck 34 24-pounders, carronades; quarter-deck 10 32-pounders, and 6 12-pounders, carronades; fore-castle, 2 32-pounders, and 2 12-pounders, carronades. Her complement of men was 875.

At the commencement of the *third period*, we have a somewhat more precise account of the armament of our ships of war. On the 16th of May 1677, a committee of the Navy Board, Ordnance, and certain naval officers, recommended to his Majesty the following scheme for arming and manning the thirty new ships of the line ordered to be built by act of Parliament.

Guns.	1st Rates.	2d Rates.	3d Rates.
Cannon (supposed 42 prs.).....	No. 26
Demi-cannon (32 prs.).....	...	26	26
Culverins (18 prs.).....	28	26	...
Twelve-pounders.....	26
Sakers, upper-deck.....	28	26	...
" Fore-castle.....	4	...	4
" Quarter-deck.....	12	10	10
Three-pounders.....	2	2	4
Total.....	100	99	70

For the 1st rate..... 780 men

For the 2d do..... 600 do.

For the 3d do..... 470 do.

The rates of ships immediately after the revolution were reduced, the first being turned to second-rates, the second-

Matériel. rates to third, &c., and the size of each class more equalized. But from this time forward it was found impossible to preserve anything like uniformity in the several classes. So many ships captured from the French, Dutch, and Spaniards, were added to our navy, and so many new ones built after the models of ships taken from these maritime powers, that the various descriptions of ships of which our navy was composed became a very serious evil.

In the year 1745, a committee, composed of all flag-officers unemployed, of the commissioners of the navy who were sea-officers, under the presidency of Sir John Norris, and assisted by the master shipwrights, were ordered to meet, to consider and propose proper establishments of guns, men, masts, yards, &c., for each class of his Majesty's ships; and, according to their recommendation, the rates, armaments, and complements of his Majesty's ships were to be as follows:—

1st rates.....	100 guns.....	850 or 750 men.
2d „	90 „	750 „ 660 „
3d „	80 „	650 „ 600 „
	70 „	520 „ 460 „
	60 „	420 „ 380 „
4th „	50 „	350 „ 280 „
5th „	44 „	280 „ 220 „
6th „	24 „	160 „ 140 „

But this establishment was very soon departed from; for on the 3d of February 1747 the Board of Admiralty acquainted his Majesty, that the French ship *Invincible*, lately captured, was found to be larger than his Majesty's ships of 90 guns and 750 men; and suggested that this ship, and all other prizes of the like class, and also his Majesty's ships of 90 guns, when reduced to two decks and a-half, and 74 guns, should be allowed a complement of 700 men. And it further appears that at the latter end of the reign of George II. the rates of ships had undergone a very material alteration, for they consisted as under:—

1st rates.....	100 guns.
2d „	90 „
3d „	80 „ 74—70—64 guns.
4th „	60 „ 50
5th „	44 „ 38—36—32 „
6th „	30 „ 28—24—20 „

The scales for measuring the ships were as various as their rates; and the evil was further increased by the varieties which it was found necessary to introduce in the rigging and arming of the ships of war. The masts, yards, rigging, and stores, were of so many and various dimensions, as to be not only highly inconvenient, but extremely expensive. When Lord Nelson was off Cadiz with 17 or 18 sail of the line, he had no less than *seven* different classes of 74-gun ships, each requiring different-sized masts, sails, yards, &c., so that in the event of one of these being disabled, the others could not supply her with such stores as could be appropriated to her wants.

To remedy the many inconveniences resulting from the irregularities above mentioned, the lords of the Admiralty suggested, by their memorial to the Prince Regent, which, by his order in Council, of the 25th November 1816, was ordered to be carried into effect, that the ships of the navy should for the future be rated as under:—

The first rate to include all three-deckers, in as much as all sea-going ships of that description carry a hundred guns and upwards.

The second rate to include all ships of 80 guns and upwards, on two decks.

The third rate to include all ships of 70 guns and upwards, but less than 80 guns.

The fourth rate to include all ships of 50 and upwards, but less than 70 guns.

The fifth rate to include all ships from 36 to 50 guns.

The sixth rate to include all ships from 24 to 36 guns.

And that the complements of men be established as *Matériel.* under:—

1st rates.....	900 — 850 or 800 men.
2d „	700 or 650 „
3d „	650 „ 600 „
4th „	450 „ 350 „
5th „	300 „ 280 „
6th „	175 — 145 or 125 „

Of sloops, the complements established according to their size were to consist of 135, 125, 95, or 75 men; of brigs (not sloops), cutters, schooners, and bombs, 60 or 50 men.

Thus at that time stood the rating and manning of the navy; but it is now as follows, viz:—

PRESENT RATING OF THE NAVY.

Classes and Denominations of Her Majesty's Ships.

1. Rated ships, that is to say, ships registered on the list of the royal navy, under one of the six following rates:—

First-rates, to comprise all ships carrying 110 guns and upwards, or whose complements consist of 950 men or more.

Second-rates, to comprise one of her Majesty's yachts, and all ships carrying under 110 guns, and not less than 80 guns, or whose complements are under 950, and not less than 720 men.

Third-rates, to comprise her Majesty's other yachts, and all such vessels as may bear the flag or pennant of any admiral, superintendent, or captain superintendent of one of her Majesty's dock-yards; and all ships carrying under 80 guns, and not less than 70; or whose complements are under 720, and not less than 600 men.

Fourth-rates, to comprise all ships carrying under 70 guns, and not less than 50, or whose complements are under 600, and not less than 440 men.

Fifth-rates, to comprise all ships under 50 guns, and not less than 30; or whose complements are under 440, and not less than 300 men; and

Sixth-rates, to consist of all other ships bearing a captain.

2. Sloops,—to comprise bomb-ships and all other vessels commanded by commanders.

3. All other ships commanded by lieutenants, and having complements of not less than 60 men.

Smaller vessels, not classed as above, to have such smaller complements as the lords commissioners of the Admiralty may from time to time direct.

The following is the present complement of ships:—

	Steam-vessels.	Sailing-vessels.
	Men.	Men.
1st rates.....	1050 to 1130	970
2d „	750 „ 930	720 to 850
3d „	600 „ 620	600 „ 650
4th „	475 „ 560	440 „ 500
5th „	300 „ 350	300 „ 375
6th „	180 „ 260	185 „ 275
Sloops	100 „ 165	80 „ 140
Smaller vessels	36 „ 90	50 „ 65

It is of the utmost importance, with a view to convenience and economy, that the size and dimensions of the several rates should be kept as nearly as possible equal, in order that one description of stores may be applicable to every ship of the same rate. To this end the commissioners of naval revision have recommended, “that the ships of each class or rate should be constructed, in every particular, according to the form of the best ship in the same class in our navy; of the same length, breadth, and depth; the masts of the same dimensions, and placed in the same parts of the ship, with the same form and size of the sails.” A complete classification of masts, yards, and sails, has since been established.

The nine line-of-battle ships previously alluded to as “the largest the world could produce,” are now far exceeded by the screw steam-ships recently built, and in course of construction,—viz., the *Victoria*, and *Howe*, each of 121 guns and 1000 horse-power; the *Royal Sovereign*, Prince of Wales, and *Marlborough*, each of 131 guns and 800 horse-power; and the *Duke of Wellington*, of 131 guns and 700 horse-power. Besides these, we have the

Matériel. Royal Albert, 121 guns, 500 horse-power; the Trafalgar, 120 guns; the Donegal, 101 guns, 800 horse-power; the Revenge, 91 guns, 800 horse-power; the St Jean d'Acre, 101 guns, 600 horse-power; the James Watt, Agamemnon, and Orion, each of 91 guns and 600 horse-power; the Princess Royal, 91 guns, 400 horse-power; the Shannon steam frigate, 51 guns, 600 horse-power; the Terrible (paddle), 21 guns, 800 horse-power; the Doris, 32 guns, 800 horse-power; and many other screw ships (including the Mersey and Orlando, both of the largest class frigates with an armament of 40 and 50 guns respectively). The large line-of-battle ships, however, are generally considered ill adapted for the ordinary purposes of war, and will probably be discontinued. The rapid increase of steam-ships in the Royal Navy has of late years been surprising, and probably ere long there will be no other class of ships or vessels afloat. Indeed this is nearly the case now. Steam corvettes and steam gun-boats supply the place of all the smaller class of vessels. There are at present 160 gun-boats on the list of the Royal Navy, of 20, 40, 60, and 80 horse-power.

Improvements in Construction.

If we look back to the days of Elizabeth, when the chain-pump, the capstan, the striking of the top-masts, the studding-sails, top-gallant-sails, sprit-sails, &c., were first introduced into the navy, one can scarcely conceive how they contrived to keep the sea for any length of time; but these improvements, important as they were, are trifling when compared with those aids and conveniences which have gradually been introduced since her reign, and which a ship of war now enjoys. When Sir Anthony Deane, in 1664, raised the lower ports of a two-decker four and a half feet out of the water, which had before been scarcely three feet, and made a ship of this class to stow six months' provisions instead of three, it was justly considered as a most important improvement; not less so, when the breadth of a ship of this class was carried to 45 feet. "The builders of England," says Pepys, "before 1673, had not well considered that breadth only will make a stiff ship." It must be confessed, however, that, as far as the form of a ship's bottom depends on scientific principles, we have copied our best models from the French, sometimes with capricious variations, which more frequently turned out to be an injurious alteration than an improvement.

The first essential alteration in the form of our ships of the line was taken from the *Superbe*, a French ship of seventy-four guns, which anchored at Spithead, on the model of which, as already stated, the *Harwich* was built by Sir Anthony Deane in 1674; since which time we have constantly been copying from French models, improving or spoiling, as chance might determine. "Where we have built exactly after the form of the best of the French ships that we have taken," say the commissioners of naval revision, "thus adding our dexterity in building to their knowledge in theory, the ships, it is generally allowed, have proved the best in our navy; but whenever our builders have been so far misled by their little attainments in the science of naval architecture as to depart from the model before them in any material degree, and attempt improvements, the true principles on which ships ought to be constructed (being imperfectly known to them) have been mistaken or counteracted, and the alterations, according to the information given to us, have in many cases done harm." Whilst, therefore, they add, "our rivals in naval power were employing men of the greatest talents and most extensive acquirements to call in the aid of science for improving the construction of ships, we have contented ourselves with groping on in the dark in quest of such discoveries as chance might bring in our way."

Upon these grounds, and by the recommendation of the

Matériel. commissioners, a school for a superior class of shipwright apprentices was established in Portsmouth dockyard. It consisted of twenty-five young men of liberal education, whose mornings were passed in the study of mathematics and mechanics, and in their application to naval architecture, and the remainder of the day under the master shipwright in the mould-loft, and in all the various kinds of manual labour connected with ship-building, as well as in the management and conversion of timber, so as to make them, at the same time, fully acquainted with all the duties in detail of a practical shipwright. After producing more officers than could be provided for, it was deemed expedient to break up the establishment.

If, however, we had hitherto been inferior to the French in the scientific principles of ship-building, in the constructive part we left them behind beyond all comparison; and notwithstanding the narrow prejudices which have been more remarkably adhered to among shipwrights than among almost any other class of artisans, various alterations and improvements have from time to time been introduced into the mechanical part of naval architecture, which have added to the strength, the stability, the comfort, and convenience of our ships of war, and rendered them, in every point of view, superior to those of any other nation. The application of iron where wood was formerly used, and of copper for iron, has added considerably to the durability of ships; and the sheathing of their bottoms with copper, to their celerity, giving them at the same time a protection against the worm and those marine insects which were wont to adhere to them; yet it is remarkable how strong the prejudice was against this practice before it obtained a due degree of credit. In the fleet of Sir Edward Hughes in India there was but one coppered ship, and Rodney's squadron in the West Indies had but four that were coppered in the year 1782; but these were enough so completely to establish their superiority over the others with wooden sheathing, that in the year 1782 the whole British navy was coppered.

But the greatest of all improvements in the construction of ships of war, as tending to their strength and durability, is the system of diagonal bracing, first introduced by Mr (afterwards Sir Robert) Seppings, surveyor of the navy, and now universally adopted in all ships of the line and frigates,—a system that may be said to have established a new era in naval architecture. Of all large machines destined to undergo severe shocks, a ship is perhaps the least skilfully and artificially contrived. Her several parts are put together on a principle so much opposed to that which constitutes strength, that if a ship on the old construction should be put upon wheels, and drawn over a rough pavement, the action of a day would shake her in pieces; but being destined to move in an element that closes upon her, and presses her equally on all sides, she is prevented from falling in pieces outwards, and her beams and decks preserve her from tumbling inwards. Whoever has observed a ship *in frame*, as it is called, on the stocks—that is, with only her timbers erected—must be forcibly reminded of the skeleton of some large quadruped, as of a horse or ox, laid on its back; the keel resembling the backbone, and the curved timbers the ribs, which is, in fact, the name by which they sometimes go. These ribs, issuing at right angles from the keel, consist, in a seventy-four gun ship, of about 800 different pieces, the space between each rib seldom exceeding five inches. These ribs are covered with a skin or planks of different thicknesses within and without, also at right angles to the ribs, and fixed to them by means of wooden pins or tree-nails. In the inside three or four tiers of beams cross the skeleton from side to side, at right angles to both planks and ribs. These beams support the decks. At right angles to the beams are pieces of wood called carlings, and at right angles to these other pieces called ledges, and upon these the planks of the deck

Matériel. are laid in a direction at right angles to the beams, and parallel to the planking of the sides. From this sketch it will be perceived that all the parts of a ship are either parallel or at right angles to each other. The ribs form a right angle with the keel, the planks inside and out are at right angles to the ribs, the beams at right angles to these, the carlings to the beams, the ledges to the carlings, and the planks of the decks to the ledges, the beams, and the ribs.

Now, it is well known to every common carpenter that this disposition of materials is the weakest that can be adopted. Thus, if five pieces of wood be pinned together in the shape of a parallelogram, it will require but little force to move them from the rectangular to the oblique or rhomboidal shape. But place a cross-bar, as in the figure Z, as carpenters are accustomed to do on a common gate, and it is no longer moveable on the points of fastening.

The strongest proof of a ship's partaking of this weakness in the old construction is afforded on her being first launched into the water, when it is invariably found that the two extremities, being less water-borne than the middle, drop, and give to the ship a convex curvature upwards, an effect which, from its resemblance to the shape of a hog's back, is usually called *hogging*. In very weak or old ships this effect may be discovered in all the port-holes of the upper-deck, by their having taken the shape of lozenges, declining different ways from the centre of the ship to each extremity.

To obviate this great defect, Seppings tried the experiment of applying to the ribs or timbers of the ship, from one extremity to the other, and from the orlop-deck downwards to the keelson, that well-known principle in carpentry, called *trussing*; being, in fact, a series of diagonal braces disposing themselves into triangles, the sides of which give to each other a mutual support and counteraction. These triangles were firmly bolted to the frame; and in order to give a continuity of strength to the whole machine, and leave no possible room for play, he filled the spaces between the frames with old-seasoned timber cut into the shape of wedges; but afterwards with a prepared cement, thus rendering the lower part of the ship or floor one solid complete mass, possessing the strength and firmness of a rock; but a few years have proved that this cement has injured the timber.

The same principle of trussing is carried from the gun-deck upwards, from whence, between every port, is introduced a diagonal brace, which completely prevents the tendency of ships to stretch, or draw asunder their upper works. The decks, too, are made subservient to the more firmly securing of the beams to the sides of the ship, by the planks being laid diagonally in contrary directions, from the midships to the sides, and at an angle of forty-five degrees with the beams, and at right angles with the ledges.

In frigates and smaller vessels, iron plates, lying at an angle of forty-five degrees with the direction of the trusses, are substituted for the diagonal frame of wood in ships of the line.

By this mode of construction, the ceiling or internal planking is wholly dispensed with, and a very considerable saving of the finest oak timber thereby effected; and, what is more important, those receptacles of filth and vermin between the timbers, which were before closed up by the planking, are entirely got rid of. This is not the least important part of the improvement, either as it concerns the soundness of the ship or the health of the crew. It is stated that a ship which had been three years in India, on

being laid open, exhibited a mass of filth, mixed up with dead rats, mice, cockroaches, and other vermin, which was taken out in cakes, not unlike in appearance the oil-cake with which certain animals are fed; that the stench was abominable, and the timbers with which it was in contact rotten. No such filth can find a lodgment in ships of war as they are now built.

It has been a subject of discussion amongst ship-builders, whether tree-nails or metallic fastenings are to be preferred. The objection to iron bolts is their rapid corrosion, from the gallic acid of the wood, the sea-water, and perhaps by a combination of both; in consequence of which the fibres of the wood around them become injured, the bolts wear away, the water oozes through, and the whole fabric is shaken and disarranged. This corrosion of iron fastenings was most remarkable when the practice of sheathing ships with copper became general, and when iron nails were made use of to fix it; for, by the contact of the two metals in the sea-water a galvanic action took place, and both were immediately corroded. Mixed metal nails are now used for this purpose; and copper bolts are universally employed below the line of flotation, though it is found that in these also oxidation takes place to a certain degree, and causes partial leaks. Various mixtures of metals have been tried, but all of them are considered as liable to greater objections than pure copper. It would appear, then, that tree-nails, if properly made, well seasoned, and driven tight, are the least objectionable, being seldom found to occasion leaks, or to injure the plank or timbers through which they pass. This species of fastening has at all times been used by all the maritime nations of Europe. The Dutch were in the habit of importing them from Ireland, it being supposed that the oak grown in that country was tougher and stronger than any which could be procured on the Continent, and in all respects best adapted for the purpose. "Under all circumstances," says Mr Knowles, "it appears that the present method of fastening ships generally with tough, well-seasoned tree-nails, with their ends split, and caulked after being driven, and securing the butts of each plank with copper bolts well clenched, is liable to fewer objections, and more conducive to the durability of the timber, than any other which has been tried or proposed to be established."

Rounding the form of the bow in ships of the line is Round considered by nautical men as of great utility and importance. The plan was first proposed by Seppings in 1807, and has since been generally adopted. The removal of the head railing, and the continuing of the rounded form, give not only great additional strength to the ship, but also much more comfort and convenience to the crew, and security in that part of the ship when in action.

The scarcity of compass or crooked timber was, for some time, attended with serious injury to those ships of war while on the stocks, into which it was considered necessary to be introduced. The difficulty with which it was procured, the length of time which a ship sometimes remained on the stocks waiting for a few pieces of compass timber, the green wood, when found, being immediately added to the seasoned timber in other parts of the frame, gave to the ship different periods of durability; though, in the long run, the seasoned parts became affected by the green wood with which they were in contact, and a premature decay of the whole fabric was the consequence. Seppings, therefore, proposed a plan in 1806, which, by uniting short timbers according to a method called *scarphing*, enabled him to obtain every species of compass-form that could be required from straight timber. Since that period, the whole frame of a ship can be prepared at once, without waiting for particular pieces, and thus every part of it can be made to undergo an equal degree of seasoning.

Matériel.

Matériel.

Plan for rendering frigate timber applicable to ships of the line.

Use of chocks abolished.

By the same ingenious and indefatigable surveyor of the navy, a plan was proposed and adopted in the year 1813, by which ships of the line were built with timber hitherto considered as applicable only to the building of frigates, and that which had been deemed only fit for inferior uses was appropriated to principal purposes. The Talavera was the first ship built on this principle, and the expense of her hull is stated to have been about L.1000 less than that of the Black Prince, a ship of similar dimensions built upon the old principle. The method by which the timbers were united was found, on trial of the Talavera with the Black Prince, whilst in frame, to give so much additional strength to the former, that it furnished the groundwork of the present mode of framing the British navy, by the introduction of the same union of materials in the application of the large as was practised in that of the small timber, and from which both strength and economy have been united.

The building of the Talavera, and the great strength of her frame, led to the practice of putting together the frames of ships of the line from timbers of reduced lengths, and dispensing altogether with the chocks used for uniting their extremities, or, as they are technically called, their *heads and heels*. These chocks are of the form of an obtuse wedge, as A, and they are used to unite the two pieces of timber, as B and C, by firmly bolting the piece A to the two timbers B and C.

It generally happened, however, that in the operation of thus fixing this chock its two extremities split, and the surfaces of the chock and timbers not being in perfect contact, the moisture and the air were admitted, and occasioned, as they always do, the dry rot to a greater degree in those parts of the ship than in most others; and as there were from 400 to 500 of these chocks in a 74-gun ship, it will readily be conceived what mischief was done to the whole fabric, if the greatest care was not taken by the workmen to prevent their splitting, and to bring their surfaces immediately into contact. It is obvious, also, that a great deal of timber must have been cut to waste in making these chocks; and, in fact, they consumed timber in each ship, when it was at a high price, to the value of from L.1500 to L.2000, besides a considerable expense in workmanship; and when the ship came to be repaired, not one chock in six was found to be in a fit state to be used again. It is not easy to conceive how this practice of uniting the timbers of a ship's frame came to be introduced so generally into the British navy, more especially as it is unknown in any other nation. It was probably first adopted to preserve the length of some particular timber, one of the ends of which being defective, the unsound part may have been cut away in the manner represented, and the sound chock introduced to fill up the vacuity. But it is quite surprising how a practice should have become general which creates a waste of timber, an increase of workmanship, and sows the seeds of premature decay. To obviate these disadvantages, Sir Robert Seppings brought the butt ends of the timbers together thus—

and kept them together by means of a round dowel or coak, as C, just as the felloes of a carriage-wheel are fastened together. He justly observes, that the simplicity of the workmanship, the economy in the conversion of timber, and the greater strength and durability, although of considerable moment, are of but trifling importance when compared with the advantage of rendering timber generally more applicable to the frames of ships which had heretofore but been partially so.

Another great improvement in the construction of ships

of war, introduced by Seppings, is the round stern, which, however unsightly it may at first appear, from our being accustomed to view the square stern, with its grotesque carved work, is even in appearance more consistent with the termination of the sweeping lines of a ship's bottom than the cutting them off abruptly with a square stern. But the additional strength which is thus given to a ship in that part which was hitherto the weakest, is alone sufficient to recommend the adoption of the plan in our ships of war, particularly in those of the larger classes. The advantages gained by circular sterns are thus enumerated by Sir Robert Seppings:—

1. They give additional strength to the whole fabric of a ship.
2. They afford additional force in point of defence.
3. They admit of the guns being run out in a similar way to those in the sides.
4. From the circular form, and mode of carrying up the timbers, an additional protection against shot is obtained if the ship should be raked.
5. The stern being equally strong as the bow, no serious injury can accrue in the event of the ship being pooped; and the ship may be moored, if so required, by the stern.
6. A ship will sail better upon a wind, from the removal of the projections of the quarter galleries.
7. Ships of the line have now a stern-walk, protected by a veranda, and so contrived that the officers can walk all round, can observe the set of the sails, and the fleet in all directions.
8. The compass-timber heretofore expended for transoms is replaced with straight timber, and worked nearly to a right angle, which affords a considerable saving in the consumption of timber.

9. The counter being done away by the circular stern, the danger from boats being caught under it is obviated.

In fact, the circular stern possesses many other advantages not necessary to be enumerated in this place.

Another important improvement in the interior construction of ships has been the substitution of iron in lieu of the clumsy wooden knees for the support of the decks.

Sir William Symonds, who was many years surveyor of the navy, and who greatly improved the build of ships of all classes, assisted by Mr Edie, was the first to reduce to a system and classify the masts and yards, the advantage of which cannot be overrated.

In the same way the armament of a ship is now brought more into a system, and it is no longer necessary to alter the fittings of the ports to allow of elevating and depressing the guns. These, and many other similar systematic arrangements—simple enough, it must be admitted—are of very recent introduction into the service.

The names of Oliver Lang, his son Oliver W. Lang, (who has built the fastest steam-vessels afloat), Fincham, and Roberts, master-shipwrights of the several yards, are also closely connected with various important improvements in ship-building in the Royal Navy.

Improvements in the Preservation of the Navy.

Not only is the new mode of construction highly favourable to the duration of ships, but the ravages of the disease which is known by the name of the dry rot, occasioned principally by the hurry in which ships were built in the course of the French war, and the unseasoned state of the timber made use of (see DRY ROT), led to such measures as tend most effectually to the preservation of the fleet.

In the first place, various modes were put in practice for assorting and seasoning the timber, and for protecting it from the vicissitudes of the weather. The oak and fir of Canada, which had been introduced to a great extent into our dockyards during the time the Baltic was shut against this country, are now excluded; these woods having been

Matériel.
Round stern.

By prevention of dry rot.

Matériel. found not only to possess little durability, but to be so friendly to the growth of fungi that they communicated the baneful disease to all other descriptions of timber with which they came in contact. The practice of building ships under cover, introduced into our dockyards in the course of the said war, and carried to an extent so as to have roofed over almost every dock and slip in all the yards, has been preventive of the progress of dry rot. (See DOCKYARDS.)

By precautions in ordinary. A ship now placed in ordinary, whether new or newly repaired, is carefully housed over, so that no rain can reach her lower decks; several streaks of planks are removed from her sides and decks to admit a thorough draft of air, which is sent down by wind-sails, and which pervades every part of the ship: and these, with the addition of two small airing-stoves, in which a few cinders are burned, render her perfectly dry and comfortable on all the decks and store-rooms. All the shingle ballast is removed out of the hold, which is thoroughly cleaned and re-stowed with iron ballast. The former practice of mooring two ships together, by which the two sides next to each other, deprived of the sun and a free circulation of air, were generally found to be decayed, is discontinued. The lower masts are left standing, and their tops housed over; the gun-carriages and several of the stores are left on board; and such, in short, is the state of a ship in ordinary, that she may be fitted in all respects for proceeding to sea in half the usual time. "The ships," says Mr Knowles, "are frequently pumped to clear them of bilge-water, and cleanliness in every respect is attended to; the lower decks are rubbed with dry stones, commonly called *holly-stones*, and with sand, the use of water upon them being strictly forbidden." But that which most of all is likely to insure the preservation of the fleet whilst in the state of ordinary, is the recent regulation which places the ordinary under the immediate superintendence of a captain at each port, with other commissioned officers under his orders, who take care that the warrant-officers and ship-keepers attend to the proper airing, ventilating, and keeping clean and dry their respective ships.

By immersion of timber in salt water. A practice had been introduced into the dockyards of steeping oak timber in salt water for several months, and then stacking it till it became perfectly dry, which is said to have entirely put a stop to the progress of dry rot where it had already commenced, and to have acted as a preventive to that disease. Some doubts, however, were entertained on this point, and the practice has been discontinued. The Americans seem to place little confidence in the good effects which are said to have been experienced from the immersion of timber. Rodgers, the commissioner of their navy, stated in an official report addressed to the secretary, that "experiments have been made to arrest the dry rot in ships, by sinking them for months in salt water, but without success. The texture of the wood was found to be essentially injured by being thus water-soaked, and it became more subject to this disease than before it was sunk. The ships were also injured in their fastenings, and the atmosphere within them was kept in a constant state of humidity, whence, among other ill effects, proceeded injury to provisions and stores, and sickness to the crews." The truth is, the American timber, with the single exception, perhaps, of the live-oak, is remarkably subject to dry rot, of which, during the war with France, we had fatal experience. Mr Rodgers, however, accounts for the condition in which the oak and pine were received in England from Canada by their immersion in water. "The Canada timber," he observes, "is brought down the St Lawrence in large rafts, continues months in water, and in that saturated state is landed and exposed to frost; every attempt to season it under cover is unavailing; its pores never close again, and when used as ship-timber dry rot ensues, which, when once commenced, can never be arrested but by taking out all the pieces in any degree affected." The Russians, he says, are

so fully aware of the injurious effects of soaking ship-timber in water, that it is brought from great distances down the rivers in crafts instead of rafts. The Russian ships, however, with all this precaution, are not remarkable for durability. The ships built at Antwerp by the French were in a state of rottenness before they were launched; but whether this was owing to the bad quality of the timber of the German forests, or to its being water-soaked in rafting down the Rhine, remains doubtful. But we can have no doubt that porous timber is injured by moisture, though the solid British oak may be improved by the dissolution of its sap juices, to the fermentation of which the disease known by name of dry rot may perhaps be chiefly owing. "Water," says Lescalier, a French writer of considerable merit on the subject, "seems to be favourable to the decomposition of the sap of timber when immersed; but it substitutes in its place another kind of moisture not less destructive, of which the timber, though afterwards exposed to the air, will not easily get rid; besides, it weakens and destroys the grain of the wood." "The best means," he adds, "of preserving timber, appears to be that of keeping it in well-constructed and airy sheds, in a vertical position, so that the moisture which remains in the interior of the logs, by running along the fibres of the wood, may be enabled to issue from the lower extremity. Timber thus kept dry, under shelter, will preserve itself for ages." Mr Knowles, secretary to the committee of surveyors of his Majesty's navy, in his treatise on the *Means of Preserving the British Navy*, is led to conclude, from a variety of experiments, "that timber is better seasoned when kept for two years and a half under cover, than when placed for six months in water, and then for two years in the air, protected from the rain and sun; that it loses more in seasoning by having been, during the six months of immersion, alternately wet and dry, than the whole time under water; and that the loss in moisture is greater in all cases in a given time when the butt ends are placed downwards." And he adds, as a general principle, "that no timber should be brought into use in this country until it has been felled at least three years." Sir William Burnett, many years physician of the navy, produced a solution for the preservation of timber and canvas, which has been found in many cases efficacious.

By roofing over them whilst building and in ordinary may be considered as the greatest of all improvements for the preservation of the navy. Next to the system of diagonal braces, the roofing thrown over them whilst building and in ordinary may be considered as the greatest of all improvements for the preservation of the navy. The utility of it is so obvious, that it is quite extraordinary such a practice should not have been earlier adopted; more especially as at Venice, at Carlsrona, and at Cronstadt, ships of war had long been built, repaired, and protected under covered roofs. It was strongly recommended to the English ship-builders sixty or seventy years ago, but without effect; and had it not been for the extraordinary ravages of the dry rot in the unseasoned timber-built ships of the navy, we should still have been without roofs to our docks and slips.

By other means. If the dockyards were of sufficient capacity, there can be no doubt that the efficient plan to accomplish their durability would be that of keeping them on the slip, when built, under cover. A large frigate, the Worcester, remained on the slip and under cover for six or seven years, and there was not a flaw in her of any kind. It was stated by Mr Strange, when examined by the commissioners for land revenue, that in the year 1790 there were twenty-two ships of the line under roofs in the port of Venice, some of which had remained in that situation fifty-nine years. Since, however, it is utterly impracticable to keep our navy on slips or in dry docks, the next important consideration is, how best to preserve them afloat in a state of ordinary. Various expedients have been at different times resorted to in order to prevent the premature decay of ships laid up in this state during peace. The two great requisites for their preserva-

Matériel.

Matériel.

tion are ventilation and cleanliness. To promote the former, wind-sails were in general use; though, if not attended to, so as to oppose the open part to the quarter from whence the wind blows, or if the weather be calm, they are of little benefit. Pneumatic machines of various kinds, as pumps and bellows, have been applied to force out the foul air, and introduce atmospherical air into the lower parts of a ship's hold. Heated air from stoves, placed in various parts of the ship, and conducted through tubes, was thought at one time to be efficacious in the preservation of the navy; but experience soon showed that the heat thus circulated was so far objectionable, as it tended to encourage the growth of fungus where there was any moisture lodged, and in the timber which had not been thoroughly seasoned. Perhaps no better means can be suggested than those we have described to be in practice,—namely, to keep them clean, to admit as much dry air as possible, and to exclude all moisture.

Finally, if we take into consideration the numerous improvements which a war, unparalleled in its duration, had been the means of introducing into the *matériel* of the navy, whether it regards the economy of its application, the construction of the ships, or their mode of preservation, we may safely say, that at no former period was this country in possession of such a navy as after the close of the war with France, in respect of the number, size, and good condition of the ships which compose a fleet superior to those of the whole world besides; and it is gratifying to find that, with all the enormous consumption of the military and mercantile navy, it does not appear that the naval resources of Great Britain were at that time at all impaired. The present state of the navy, at the close of another great war, in which its resources were in some respects severely tried, is no less satisfactory.

Naval Resources.

It is of essential importance that the supply of stores for the use of the fleet should not only be adequate to the demand, but that a sufficient stock should be kept on hand to answer any sudden emergency. This is the more necessary with regard to those species of stores which are derived from foreign nations.

Principal naval stores.

Hemp.

Pitch and tar.

The principal articles of consumption required for building and equipping a fleet are,—hemp, canvas, pitch, tar, iron, copper, and timber. All these articles might unquestionably be produced in sufficient quantities in the united kingdom and her colonies, if necessity absolutely required it. Hemp, for instance, might be grown to any extent in Great Britain and Ireland, were not the land more advantageously employed in raising other articles of consumption, and if it could not be cheaper imported from Russia. In the East Indies, the Sunn hemp (inferior, it is true, to Russian hemp) might be procured to any extent; and other plants, both there and at home, might be substituted for the making of cordage and canvas. For pitch and tar recourse might be had to the pitch-lake on the island of Trinidad, and the coal-tar, of which an inexhaustible supply may be had at home. The lake is about four miles in circumference, and many feet in depth, of solid pitch; and it is stated that, when mixed with oil or tallow, it is rendered fit for all the purposes to which pitch and tar are usually applied. It has the advantage of securing ships' bottoms against the attack of the worm, which is very active in the neighbouring gulf of Para; and it does not corrode iron. The coal-tar of home manufacture, from some prejudice or other, was refused a fair trial till very lately, and it is now deemed not inferior for many purposes to the common tar. For painting or tarring over wood-work of every kind, it is said to stand exposure to the weather even better than the common tar; and it is used for injecting, in large quantities, between the timbers of ships, as a preservative from the dry rot; its powerful

smell having also the good effect of driving rats and other vermin out of the ships in which it is employed.

Matériel.

In the two important articles of copper and iron, our own resources may be considered as inexhaustible. Formerly iron.

It was deemed indispensable that certain articles should be made of Swedish iron; but of late years our own has been manufactured in every respect equally good; and the extensive application of this metal in bridges, barges, dock-gates, roofs, rafters, floors, &c., has been equally progressive in most naval purposes. Iron knees, and other modes of binding the beams to the side timbers of ships, are now substituted for those large and crooked pieces of timber, as already stated, which were once deemed absolutely necessary. Our cables, rigging, buoys, and tanks for holding water, are also now of iron. A few steam-vessels have also been constructed of iron; but from experiments made by firing at them, they have been found wholly unsuited for purposes of war, the shot passing through their side, and leaving frightful rents, which, if struck between wind and water, would speedily cause them to fill and sink. It is therefore assumed that they will be discontinued in the Royal Navy.

Iron ships.

But the most important article of demand for the use of the navy is timber, principally oak, concerning the supply

Timber.

of which from our own territories different opinions have been entertained. A deficiency in other articles may readily be supplied. A failure in the importation of hemp, for instance, in any one year, might be remedied the next, by an extended cultivation of that article; but it requires a whole century to repair any defalcation of oak timber, and to render us independent of other nations. Nor has the subject been sufficiently elucidated, so as to form a just opinion, by the several committees of the House of Commons, the evidence produced being almost always loose, and generally contradictory. The committee of 1771, which was directed to inquire into the state of oak timber throughout the kingdom, either from a disagreement of opinion, or defect of evidence, or a wish to avoid giving alarm, prayed the House to discharge that part of its order which required them to report their opinion. The Commissioners of Woods and Forests, however, in their report laid before Parliament in 1792, appeared to establish the fact of an alarming scarcity of oak timber in general, but more particularly of large naval timber, both in the royal forests and on private estates. And if such was really the fact in 1792, it will readily be conceived what the state of timber fit for naval purposes must have been at the conclusion of the revolutionary war, when the amount of private shipping had increased from 1,300,000 tons to 2,500,000 tons, or nearly doubled; that of the East India Company, in the same period, from 79,900 tons to 115,000 tons; and that of the navy from 400,000 to 800,000 tons: to say nothing of the vast consumption of oak timber in all kinds of mill-work and other machinery; in the barrack and ordnance departments; in mines, collieries, and agriculture; in docks and dock-gates; in piers, locks, and sluices; in boats, barges, lighters, bridges, and a great many other purposes to which this timber is applied. From these and many other causes, the diminution of oak timber was infinitely greater than the commissioners had calculated upon, and yet they recommended that 100,000 acres belonging to the crown should be set apart and planted for the future supply of the navy. A bill to this effect, relating to the New Forest, passed the Commons, but was thrown out by the Lords.

On the departments of the surveyor-general of the land revenue and the surveyor-general of the woods and forests being united, the board of commissioners made their first report, which was printed, by order of the House of Commons, in June 1812. In this report, it is stated that, taking the tonnage of the navy in 1806 at 776,087 tons, it would require, at one load and a half to a ton, 1,164,085 loads to build such a navy; and supposing the average duration of

Report of the Commissioners of Land Revenue respecting timber.

Matériel. a ship to be fourteen years, the annual quantity of timber required would be 83,149 loads, exclusive of repairs, which they calculate would be about 27,000 loads, making in the whole about 110,000 loads; of which, however, the commissioners reckon, may be furnished 21,841 loads as the annual average of prizes; and of the remaining 88,659 loads, they think it not unreasonable to calculate on 28,659 from other sources than British oak. "This," they observe, "leaves 60,000 loads of such oak as the quantity which would be sufficient annually to support, at its present unexampled magnitude, the whole British navy, including ships of war of all sorts, but which may be taken as equivalent together to 20 74-gun ships, each of which, one with another, contains about 2000 tons, or would require, at the rate of a load and a half to the ton, 3000 loads, making just 60,000 loads for 20 such ships."

Quantity of timber required for the navy.

Now it has been supposed that not more than forty oak trees can stand on an acre of ground, so as to grow to a full size, fit for ships of the line, or to contain each a load and a half of timber; 50 acres, therefore, would be required to produce a sufficient quantity of timber to build a 74-gun ship, and 1000 acres for 20 such ships; and as the oak requires at least 100 years to arrive at maturity, 100,000 acres would be required to keep up a successive supply for maintaining a navy of 700,000 or 800,000 tons. The commissioners further observe, that as there are 20,000,000 of acres of waste lands in the kingdom, a two-hundredth part set aside for planting would at once furnish the whole quantity wanted for the use of the navy.

This calculation, we suspect, is overrated by about one-half. In the first place, it supposes a state of perpetual war, during which the tonnage of the whole navy is considered as more than double of what it is in time of peace; and in the second place, it reckons the average duration of the navy at fourteen years only, which, from the improvements that have taken place in the construction and preservation of ships of war, with the resources of teak ships, built in India, we should not hesitate in assuming at an average of twice that number of years; and if so, the quantity of oak required for the navy will be nothing like that which the commissioners have stated. This, we think, will appear from a statement made (apparently on good authority) in the midst of the war, when the ships of the line built in merchants' yards were falling to decay after a service of five or six years.

"Assuming 400,000 tons as the amount of tonnage to be kept in commission, and the average duration of a ship of war at the moderate period of twelve and a half years, there would be required an annual supply of tonnage, to preserve the navy in an effective state, of 32,000 tons; and as a load and a half of timber is employed for every ton, the annual demand will be 48,000 loads. The building of a 74-gun ship consumes about 2000 oak trees, or 3000 loads of timber; so that 48,000 loads will build eight sail of the line and sixteen frigates. Allowing one-fourth part more for casualties, the annual consumption will be about 60,000 loads, or 40,000 full-grown trees, of which thirty-five will stand upon an acre of ground. The quantity of timber, therefore, necessary for the construction of a 74-gun ship will occupy fifty-seven acres of land, and the annual demand will be the produce of 1140 acres. Allowing only ninety years for the oak to arrive at perfection, there ought to be now standing 102,600 acres of oak plantations, and an annual felling and planting, in perpetual rotation, of 1140 acres, to meet the consumption of the navy alone. Large as this may seem, it is little more than twenty-one acres for each county in England and Wales, which is not equal to the belt which surrounds the park and pleasure-grounds of many estates."

The above calculation proceeds upon the principle that every acre is covered with trees fit for naval purposes, or

that it contains thirty-five trees, with a load and a half of timber in each. It may be doubted, however, if on the average of plantations we shall find more than one-tenth of that number on an acre; and as the same writer endeavours to show that the quantity of oak timber consumed in the navy is only about one-tenth part of the whole consumption of the country, instead of 102,600 acres being sufficient for a perpetual supply, there would be required some ten or twelve millions of acres, in plantations similar to those at present existing, to supply the demand for oak timber. Whether such a quantity exists or not, the fact is certain, that, before the conclusion of the long war, a scarcity began to be felt, especially of the larger kind of timber, fit for building ships of the line; and so great was this scarcity, that if Sir Robert Seppings had not contrived the means of substituting straight timber for those of a certain form and dimension, before considered as indispensable, the building of new ships must have entirely ceased.

If, however, the growth of oak for ship-timber was greatly diminished during the war, so as to threaten an alarming scarcity, there is little doubt that, from the increased attention paid by individuals to their young plantations, and the great extension of those plantations, as well as from the measure of allotting off portions of the royal forests to those who had claims on them, and inclosing the remainder for the use of the public, this country will, in future times, be fully adequate to the production of oak timber equal to the demand for the naval and mercantile marine. It will require, however, large and successive plantations, on account of the slow growth of the oak. But there is another tree, of late years very generally planted on rising grounds, which bids fair to become an object of great national importance, as furnishing the best, and perhaps the only substitute for oak timber. We mean the larch, which thrives well and grows rapidly in bad soils and exposed situations, the timber of which has been found to be durable, and, from several experiments, not inferior in strength, toughness, and elasticity to oak. So rapid is its growth, that the Duke of Atholl received twelve guineas for a single larch fifty years old; the timber was valued at two shillings a foot. A larch of seventy years' growth produces timber fit for all naval purposes, and may be considered as equal in size to an oak of double that age. The dimensions of a larch tree cut down at Blair Atholl in 1817, and then seventy-nine years of age, were as follows, viz.:—Stem, 82 feet; top, 20 feet; total height, 102 feet; girth at the ground, 12 feet; at 19 feet, 8 feet 3½ inches; and at 57 feet, 4 feet 10 inches: solid contents, 252·8 cubic feet. Another larch, growing at Dunkeld, measured in the year 1819, when it was eighty years old, and in full vigour, as follows, viz.:—Height of stem, 75 feet; top, 14 feet; total height, 90 feet; at 1 foot from the ground, 17 feet 8 inches in girth; at 10 feet, 10 feet 4 inches; and at 70 feet, 3 feet 2 inches: its contents, 300 cubic feet, or six loads. For all kinds of mill-work, as wheels, axle-trees, &c., the utility of the large larch wood is unquestionable; and the thinnings are excellent for paling, rails, and hurdles. The value of its application for naval purposes has been put to the test of experiment; two frigates of 28 guns, one built entirely of larch from the Duke of Atholl's plantations, the other of Riga fir (which was considered inferior only to oak), having been intended to go through the same service, precisely in the same parts of the world, in order to ascertain their comparative durability. What was the result of the experiment we are not aware, beyond the fact, that the Atholl, which was one of the frigates, is still a good, sound ship, in commission at Greenock, though built, we believe, some forty years ago.

In addition to our resources of naval timber at home, we Indian have wisely availed ourselves of those which India affords for teak. building ships of war at Bombay, of teak, a wood far superior in every respect to oak, and many times more durable, not

Matériel.

Value of larch for shipbuilding.

Personnel. liable to corrode iron or other metallic fastenings, not susceptible of the dry rot, nor subject to the attack of the worm.

II.—PERSONNEL OF THE NAVY.

The *personnel* of the navy is composed of two different bodies of men, the seamen and the marines, each of whom have their appropriate officers.

The officers of the navy are divided into two distinct branches—the military and the civil. The military, or executive branch, consists of flag-officers, commodores, captains, commanders, lieutenants, masters of the fleet, masters, mates, second masters, midshipmen, masters' assistants, naval cadets, gunners, boatswains, carpenters.

**Commiss-
ioned offi-
cers.**

Flag-officers are divided into three ranks, and each rank into three squadrons, distinguished by the colours red, white, and blue: as admiral of the red, white, or blue; vice-admiral of the red, white, or blue; rear-admiral of the red, white, or blue: the admiral wearing his colour at the main, the vice-admiral at the fore, and the rear-admiral at the mizen mast head. There is also an admiral of the fleet, who, if in command, would carry the union flag at the main. There are, besides, flag-officers on reserved half-pay, divided into three ranks, to which they rise by seniority; and superannuated rear-admirals, enjoying the rank and pay of a rear-admiral, but incapable of rising to a higher rank on the list, which is considered a grievance. The rank of commodore is temporary: he is generally an old captain, and is distinguished by wearing a broad pennant. He ranks next to the junior rear-admiral, and above all captains, except where the captain of the fleet shall be a captain who, in that situation, takes rank next to the junior rear-admiral.

The commissioned officers of the navy take rank with those of the army as follows:—

Navy.	Army.
Admiral of the fleet.....	Field-Marshal.
Admiral.....	General.
Vice-admiral.....	Lieutenant-General.
Rear-admiral.....	Major-General.
Commodore (1st and 2d class)...	Brigadier-General.
Captain of three years.....	Colonel.
Captain under ditto.....	Lieutenant-Colonel.
Commander.....	Major.
Lieutenant.....	Captain.
Master.....	
Mate.....	Lieutenant.
Second Master. }	Ensign.
Midshipmen. }	

And all officers of the same rank command according to the priority of their commissions, or, having commissions of the same date, according to the order in which they stand on the list of the officers of the navy; except in the case of lieutenants of flag-ships, who take precedence according as the flag-officer shall think fit to appoint them.

The civil branch consists of the director-general of the medical department of the navy (who ranks with a brigadier-general), medical inspectors of hospitals and fleets, and deputy-medical inspectors (who rank with lieutenant-colonels and majors), chaplains, secretaries to commanders-in-chief and commodores of first class, surgeons, paymasters (formerly pursers), assistant surgeons, assistant paymasters, naval instructors, clerks, clerks' assistants, inspectors of machinery, chief engineers, and assistant engineers of 1st, 2d, and 3d class.

**Warrant-
officers.**

The warrant-officers of the navy may be compared with the non-commissioned officers of the army. They take rank as follows, viz.:—Gunner, boatswain, carpenter.

**Petty offi-
cers.**

The petty officers are very numerous; they consist of chief petty officer, and 1st and 2d class working petty officers. Their names or ratings will be seen in the table of the establishment of the ratings and pay in the several classes of ships of war.

By the Queen's order in Council, the following regulations

are established for the promotion of commissioned officers **Personnel.** of the navy. Midshipmen are required to serve five years on board some of Her Majesty's ships, three years and six months of which they must have been rated as midshipmen, **Order of promotion.** to render them eligible to the rank and situation of lieutenant; and they must be nineteen years of age. They enter the navy between the age of thirteen and fifteen as naval cadets, in which rank they are required to serve eighteen months, the first three of which in a training ship; and at the end of the five years they are rated mates, and so continue till promoted. There are several intermediate examinations required to be passed by them.

No lieutenant can be promoted to the rank of commander until he has been on the list of lieutenants during two years, and has served that period at sea; and no commander to the rank of captain until he has been on the list, and has served at sea one year. Captains become admirals in succession according to their seniority on the list, provided they shall have commanded four years in a rated ship during war, or six years during peace, or five years in war and peace combined.

No person can be appointed to serve as master of one of Her Majesty's ships who shall not have served as second master; and no person can be appointed as second master until he has passed such examination as may from time to time be directed.

No person can be appointed gunner unless he shall have served seven years, one of which as gunner's mate or other petty officer, or seaman gunner, on board one or more of Her Majesty's ships; and he must produce certificates of his good conduct, and undergo the necessary examination.

No person can be appointed boatswain unless he shall have served seven years,—one complete year with the rating, and actually doing the duty of a petty officer in Her Majesty's navy; and he must produce certificates of good conduct, and undergo the necessary examination.

No person can be appointed carpenter unless he shall have served an apprenticeship to a shipwright, and been six months a carpenter's mate or caulker, or twelve months with the rating of carpenter, on board one or more of Her Majesty's ships.

No person can be appointed chaplain to one of Her Majesty's ships until he has received priest's orders; but he may be appointed to act whilst in deacon's orders.

No person can be appointed paymaster unless he shall have been rated, and have discharged the duties of a captain's clerk for three complete years; or two years as captain's clerk, and one year clerk to a secretary of a flag-officer; and been employed in the office of the secretary to a flag-officer for one other year; and shall produce good certificates, and find such security for the honest and faithful discharge of his duty as shall be required.

No person can be appointed surgeon to one of Her Majesty's ships until he has discharged the duties of assistant-surgeon for three years, one of which at sea; and all persons applying for the situation of assistant-surgeon must undergo an examination touching their qualifications before the medical director-general of the navy.

The Royal Marines, recently made light infantry, consist of four great divisions; the first stationed at Chatham, the second at Portsmouth, the third at Plymouth, and the fourth at Woolwich. They are composed of 104 companies besides fourteen companies of Royal Marine artillery, whose head-quarters are at Portsmouth. The first division has twenty-five companies, the second twenty-seven companies, the third twenty-seven companies, and the fourth twenty-five companies. The officers of Royal Marines take rank with the officers of the line in the army.

The deputy adjutant-general, who is a major-general, and the assistant adjutant-general, who is a lieutenant-colonel in the corps, are resident in London; and to each

Personnel. of the divisions is attached a colonel-commandant and a colonel and second commandant, a proper number of lieutenant-colonels, captains, and subaltern officers. Whilst on shore the marines are subject to the same regulations as the army; but when embarked they are liable to the naval articles of war, and to the Marine Mutiny Act.

Each division has two or more adjutants; two quartermasters, who are all first lieutenants; a paymaster, who is a captain in the corps; and barrackmaster, also a captain; and to each division is a deputy-inspector of hospitals, or staff-surgeon and two assistant-surgeons. There is also a retired list of officers, who, in consideration of wounds, infirmities, and long and meritorious services, are permitted to receive their full pay, and also a reserved half-pay list.

The commissions of officers of every rank in the marine corps are signed by the sovereign; but all commissions of officers of the navy are signed by two or more of the lords commissioners of the Admiralty. But the marines, whether ashore or afloat, are, as well as the officers of the navy, under the immediate direction and control of the lords commissioners of the Admiralty. All the appointments of commissioned and warrant officers to ships are made exclusively by the lords of the Admiralty, or made subject to their confirmation, unless in cases of the death or dismissal of officers by sentence of court-martial on foreign stations, when the admiral commanding has the power to fill up the vacancies. And the duties of each rank are pointed out in a code of instructions emanating from that board, and sanctioned by the sovereign's order in Council.

Military duties of the Lord High Admiral.

The civil powers and duties of the Lord High Admiral, or lords commissioners of the Admiralty, are treated of under the article ADMIRAL. Their military powers are more extensive and important. By their orders all ships are built, repaired, fitted for sea, or laid up in ordinary, broken up, or sold; put in commission or out of commission, armed, stored, and provisioned; and employed on the home or foreign stations, or on voyages of discovery. All appointments or removals of commission and warrant officers are made by them, and all instructions issued for the guidance of their commanders; all promotion in the several ranks emanates from them; all honours bestowed for brilliant services, and all pensions, gratuities, and superannuations for wounds, infirmities, and long services, are granted on their recommendation. All returns from the fleet are sent to the Board of Admiralty, and everything that relates to the discipline and good order of every ship. All orders for the payment of naval monies are issued to the accountant-general of the navy by the lords commissioners of the Admiralty; and the annual estimate of the expenses of the navy is prepared by them, and laid before Parliament for its sanction. All new inventions and experiments are tried by their orders before being introduced into the service; all draughts of ships must be approved by them; all repairs, alterations, and improvements in the dockyards, and all new buildings of every description, must be submitted for their decision before they are undertaken.

Commander-in-chief.

All flag-officers, commanders-in-chief, are considered as responsible for the conduct of the fleet or squadron under their command. They are bound to keep them in perfect condition for service; to exercise them frequently in forming orders of sailing and lines of battle, and in performing all such evolutions as may occur in the presence of an enemy; to direct the commanders of squadrons and divisions to inspect the state of each ship under their command; to see that the established rules for good order, discipline, and cleanliness, are observed; and occasionally to inquire into these and other matters themselves. They are required to correspond with the secretary of the Admiralty, and report to him all their proceedings.

If a commander-in-chief should be killed in battle, his

flag is to be continued flying, and intelligence conveyed, by signal or otherwise, to the next in command, who is immediately to repair on board, leaving his own flag (if a flag-officer) flying, and direct the operations of the fleet until the battle be ended, or the enemy out of sight.

Every flag-officer serving in a fleet, but not commanding it, is required to superintend all the ships of the squadron or division placed under his orders; to see that their crews are properly disciplined; that all orders are punctually attended to; that the stores, provisions, and water, are kept as complete as circumstances will admit; that the seamen and marines are frequently exercised; and that every precaution is taken for preserving the health of their crews; for all which he is responsible to the commander-in-chief. When at sea, he is to take care that every ship in his division preserve her station, in whatever line or order of sailing the fleet may be formed; and in battle he is to observe attentively the conduct of every ship near him, whether of the squadron or division under his immediate command or not; and at the end of the battle he is to report it to the commander-in-chief, in order that commendation or censure may be passed, as the case may appear to merit; and he is empowered to send an officer to supersede any captain who may misbehave in battle, or whose ship is evidently avoiding the engagement. If any flag-officer be killed in battle, his flag is to be kept flying, and signals to be repeated, in the same manner as if he were still alive, until the battle shall be ended; but the death of a flag-officer, or his being rendered incapable of attending to his duty, is to be conveyed as expeditiously as possible to the commander-in-chief.

Personnel.

Other flag-officers.

The captain of the fleet is a temporary rank, where a commander-in-chief has ten or more ships of the line under his command; it may be compared with that of adjutant-general in the army. He may either be a flag-officer, or one of the senior captains; in the former case, he takes his rank with the flag-officers of the fleet; in the latter, he ranks next to the junior rear-admiral, and is entitled to the pay and compensation of a rear-admiral. All orders of the commander-in-chief are issued through him, all returns of the fleet are made through him to the commander-in-chief, and he keeps a journal of the proceedings of the fleet, which he transmits every three months to the Admiralty. He is appointed and can be removed from his situation only by the lords commissioners of the Admiralty.

Captain of the fleet.

A commodore is a temporary rank, and of two kinds; the one having a captain under him in the same ship, and the other without a captain. The former has the rank, pay, and allowances of a rear-admiral, the latter such additional pay as the lords of the Admiralty may direct. They both carry distinguishing pennants.

Commodore.

When a captain is appointed to command a ship of war, he commissions the ship by hoisting his pennant; and if fresh out of the dock, and from the hands of the dockyard officers, he proceeds immediately to prepare her for sea, by demanding her stores, provisions, guns, and ammunition, from the respective departments, according to her establishment. He enters such men as may volunteer and be fit for the service (in time of peace), or who may be sent to him from some rendezvous for raising men; and he gives them the several ratings of petty officers, leading seamen, able seamen, ordinary, or landsmen, as their apparent qualifications may entitle them to. If he be appointed to succeed the captain of a ship already in commission, he passes a receipt to the said captain for the ship's books, papers, and stores, and becomes responsible and accountable for the whole of the remaining stores and provisions; and, to enable him to keep the ship's accounts, he is allowed one or more clerks or clerks' assistants.

Captain.

The duty of the captain of a ship, with regard to the several books and accounts, pay-books, entry, musters, dis-

Personnel.

charges, &c., is regulated by various acts of Parliament; but the state of the internal discipline, the order, regularity, cleanliness, and the health of the crews, will depend mainly on himself and his officers. In all these respects the general printed orders for his guidance, contained in the present edition of the Queen's regulations and Admiralty instructions, prepared by Sir George Cockburn (aided by Mr Barrow), and issued to the fleet in 1844, are particularly precise and minute. And, for the information of the ship's company, he is directed to cause the articles of war, and abstracts of all acts of Parliament for the encouragement of seamen, and all such orders and regulations for discipline as may be established, to be hung up in some public part of the ship, to which the men may at all times have access. He is also to direct that they be read to the ship's company, all the officers being present, once at least in every month. In every ship where there is a chaplain, he is desired to be particularly careful that the attention and respect due to his sacred office be shown to him by all the officers and men, and that divine service be performed, and a sermon preached, every Sunday. He is not authorized to inflict any corporal punishment on any commissioned or warrant officer, but he may place them under arrest, and suspend any officer who shall misbehave, until an opportunity shall offer of trying such officer by a court-martial. He is enjoined to be very careful not to suffer the inferior officers or men to be treated with cruelty and oppression by their superiors. He alone is to order punishment to be inflicted, which he is never to do without sufficient cause, nor ever with greater severity than the offence may really deserve, nor until twenty-four hours after the crime has been committed, which must be specified in the warrant ordering the punishment; and all the officers and the whole ship's company are to be present at every punishment, which must be inserted in the log-book, and an abstract at the end of every quarter made out and sent to the Admiralty; a regulation which has been attended with infinite benefit to the strict and just discipline of the naval service. The greatest number of lashes he can inflict is 48. The total abolition of flogging, so often advocated, can never, in the opinion of any officer, be advantageously carried into effect; but it would seem desirable to reduce the number of lashes to 24, considering the extreme severity of the punishment and pain inflicted, which often renders the man totally unfit for duty for some days. The disgrace attending the punishment is more likely to deter others than the pain inflicted. In a few well-regulated ships corporal punishments are quite unknown during the whole period of their commission. It was never found necessary in any ship employed in the Arctic squadron, owing to the great regularity observed on board, to daily prayers being read, and to there being little or no drunkenness. With a view to checking the flogging in the navy, a return is annually called for by Parliament, and a column inserted showing the number of lashes sentenced, and the numbers inflicted, together with the highest number of lashes given in any one case, and the lowest, together with a sum total.

Lieutenant.

The lieutenants take the watch by turns, and are at such times intrusted, in the absence of the captain, with the command of the ship. The one on duty is to inform the captain of all occurrences which take place during his watch; as strange sails that may be in sight, signals from other ships in company, change of wind, &c. He is to see that the ship be properly steered, the log hove, and the course and distance entered on the log-board; and, in short, he is to see that the whole of the duties of the ship are carried on with the same punctuality as if the captain himself were present. In the absence of the captain, the senior lieutenant is responsible for everything done on board.

Master.

The master receives his orders from the captain or any of the lieutenants. His more immediate duties are those

of stowing the ship's hold, and of attending to her sailing qualities; of receiving and placing the provisions in the ship, so as most conveniently to come at those which may be wanted. He is to take care that the cables are properly coiled in the tiers. The keys of the spirit-room are in his custody, and he is directed to intrust them only to the master's assistants. He has the charge of the store-rooms of the warrant-officers, which he is ordered frequently to visit; in short, the whole of the ship's provisions, water, fuel, and stores of every description, are under the superintendence of the master; and he is also intrusted, under the command of the captain, with the charge of navigating the ship, bringing her to anchor, ascertaining the latitude and longitude of her place at sea, surveying harbours, and making such nautical remarks and observations as may be useful and interesting to navigation in general. He keeps the ship's log-book and remark-book. For distinguished conduct masters are eligible for promotion to the rank of lieutenant; but few would accept it, except with a certain prospect of rising to the higher grades, of which there are instances.

The warrant-officers are charged with the duty of receiving on board from the dockyards, and examining, the various stores of their respective departments, and keeping an account of the expenditure of them.

The gunner has the charge of the ship's artillery and of the powder magazine. He is to see that the locks and carriages are kept in good order, and that the powder is preserved from damp; he is frequently to examine the musketry and small arms, and to see that they are kept clean and fit for service; and, in preparing for battle, it is his duty to take care that all the quarters are supplied with everything necessary for the service of the guns, and, during the action, that there be no want of ammunition served out. He is frequently to exercise the men at the guns, and to see that they perform this part of their duty with correctness, explaining and enforcing the necessity of their pointing the guns before they fire them, spunging them well, and close-stopping the touch-hole immediately after firing. The armourer and his mates are under the immediate orders of the gunner in everything that relates to the great guns and small arms.

The boatswain is charged with the duty of receiving and examining all the stores belonging to his department, consisting chiefly of the ropes and rigging, the latter of which he is ordered to inspect daily, in order that any part of it chafed or likely to give way may be repaired without loss of time. He is always required to be on deck at such times as all hands are employed; he is bound to see that the men, when called, move quickly upon deck, and when there, that they perform their duty with alacrity, and without noise or confusion. The sailmaker and the ropemaker are under his immediate orders.

The carpenter, when appointed to a ship, is carefully to inspect the state of the masts and the yards, whether in the dockyard or on board of the ship, to see that they are perfectly sound and in good order. He is to examine every part of the ship's hull, magazine, store-rooms, and cabins. He is every day when at sea carefully to examine into the state of the masts and yards, and to report to the officer of the watch if any appear to be sprung, or in any way defective. He is to see that the ports are secure and properly lined, and that the pumps are kept in good order, as also the boats, ladders, and gratings. The caulker is placed under his immediate orders, and he is to see that the former performs his duty in a workmanlike manner, in stopping immediately any leaks that may be discovered.

The engineer, when first appointed to a steam-vessel, carefully examines the engines, paddles (or screw), and the boilers, and reports to the commanding officer any defects he discovers. He takes charge of all the engineers' stores and tools, and keeps account of receipts and expenditure.

Personnel.

Personnel. He is never to quit the engine-room during his watch, and visits it frequently at all times day and night. The leading stoker and stokers are under his immediate control.

Paymaster. The paymaster (formerly purser) has the charge of all the ship's provisions, and of the serving them out for the use of the crew. His charge is, therefore, of a most important matter; and, accordingly, he must not only produce good certificates of his conduct whilst serving in the capacity of clerk, but must also find two sureties for the due discharge of his trust, who are required to give bond in a penal sum, according to the rate or class of ship to which he may be appointed. The regulations and instructions for his guidance are minutely detailed in the general printed instructions, with all the various forms established for the keeping of his accounts with the accountant-general and comptroller of victualling, to whom he is immediately responsible. To assist him in the performance of his arduous duties, he is allowed to employ the clerk, with the sanction of the captain, who is responsible for the strict performance of the duties of all the officers under his orders, and acts, as it were, as a check on the paymaster in many parts of his duty, regarding the slop-books, muster-books, &c. He has also a steward under his immediate orders.

Other officers. The duties of the medical inspectors of hospitals and fleets, the surgeon of a ship and his assistants, the secretary to the commander-in-chief, the chaplain, the naval instructor, and inspectors of machinery afloat, are too obvious to require any specification.

Midshipmen and naval cadets. The midshipmen are considered as the principal petty officers, but have no specific duties assigned to them. In the smaller vessels, some of the senior ones are intrusted with the watch; they attend parties of men sent on shore; pass the word of command on board, and see that the orders of their superiors are carried into effect; in short, are exercised in all the duties of their profession, so as, after five years' service (eighteen months as cadet, and three years and six months as midshipmen), to qualify them to become lieutenants; and are then rated mates, provided they have passed the requisite examination, and are nineteen years of age.

Marines. Every ship, according to her class, has a certain number of marines as part of her complement. They are commanded by a captain or brevet-major, in from first to fourth rates inclusive, with three or two subalterns under them, and an established number of non-commissioned officers; but the party on board fifth rates and under is commanded by a subaltern, and in small vessels by a sergeant or corporal.

All marine officers, of whatsoever rank, when embarked, are to obey the orders of the captain or the commanding officer of the watch. The marines are exercised by their officers in the use of their arms; they are employed as sentinels, and in all other duties on board of which they are capable, with the exception of going aloft. The officer commanding has the charge of the arms, accoutrements, and drums; and he is to inspect, weekly at least, the state of the clothing of his party. The marines are in every respect treated as part of the ship's company.

Number of commissioned officers. The long continuance of the revolutionary war necessarily created a prodigious increase of the commissioned officers of the navy. Their numbers in the five following years of peace were,—

	1793.	1803.	1815.	1821.	1836.
Admirals	11	45	70	63	43
Vice-admirals	19	36	73	59	59
Rear-admirals	19	51	77	68	63
Captains	444	666	824	828	755
Commanders	160	410	762	776	823
Lieutenants	1408	2461	3211	3797	2976

Personnel. In the year 1857 there were on the active list of the navy 371 captains, 530 commanders, 1122 lieutenants; and on the retired and reserved list 129 captains, 243 commanders with rank of captain (besides 113 commanders on reserved half-pay), 254 lieutenants with rank of retired commanders (besides 618 on reserved half-pay). The total number of captains was therefore 743; commanders, 897; lieutenants, 1740; being a diminution of considerably upwards of 1000 officers of the foregoing ranks, as compared with the list in 1836.

The warrant-officers have increased from the average of about 400 in 1793 and 700 in 1821, to upwards of 1000 in 1857. They are divided into two classes,—viz., those who are fit for sea service, and those who are fit for harbour duty. The latter consist of about 150 gunners, boatswains, and carpenters. The total number of officers of the Royal Navy and Royal Marines in 1857 was upwards of 7300, excluding mates and midshipmen, clerks, warrant-officers, and engineers. These may be computed at 3000; making a grand total of 10,300 officers of all ranks.

The number of seamen and marines voted in 1792 was 16,000 (but never reduced to that number); in 1822 it was 21,000; in 1836, 32,000; 1840–1, 35,165; 1850–1, 39,000; 1853–4, 45,500; and in 1854–5, 48,000. The greatest number of seamen and marines voted in any one year during the French war was 150,000, and during the war with Russia, 76,000.

All officers of the navy wear a uniform, which is established in pursuance of the pleasure of the sovereign. It consists of blue cloth, with white collars and cuffs to the coats, and various embroidery and epaulets. The epaulets of the officers of the civil branch of the service are embroidered in gold and silver. The full dress, with cocked hats, is worn, on state occasions and at courts-martial, by all naval officers. The first naval uniform (blue and white) was established in 1748. The identical patterns then issued may now be seen in the United Service Institution. They were obtained a few years since from Plymouth, where they had been carefully preserved. In the reign of William IV. the facings were for a short time changed to red. The last alteration of the uniform was in 1856. The petty officers, seamen, and boys also wear certain regulated articles of dress; the former with marks of distinction on the left sleeve of their jackets. The seamen, too, wear good-conduct badges.

The crew of a ship of war consists of leading seamen, Ship's able seamen, ordinary seamen, landsmen, leading stokers, company stokers, coal-trimmers, boys, and marines. The landsmen, boys, and marines, are always entered voluntarily, the latter in the same manner as soldiers, by enlisting into the corps, the two former at some rendezvous or on board particular ships. A supply of boys for the navy is also regularly sent from the Asylum at Greenwich and the Marine Society. Able and ordinary seamen also very commonly volunteer to serve during the war, and always in time of peace; but the high wages given by the merchant ships to seamen in time of war hold out such encouragement as to induce them to give the preference to that service, though in all other respects their treatment is far superior on board a Queen's ship, having better provisions, being subject to much less fatigue and exposure to the weather, well taken care of in sickness, and being entitled to pensions after twenty-one years' service, or when disabled. Indeed, the excellent regulations now rigidly adhered to on board H.M.'s ships, and the attention that is paid to the health and comfort of the crew, have overcome much of that reluctance which formerly was felt to the service of a ship of war.

The state of health on board of a Queen's ship is, generally speaking, not exceeded in the most favoured spot on shore; and that horrible disease, the sea-scurvy, may now be considered as unknown in the British navy, since the universal

Personnel. introduction of lemon juice, or the citric acid, without an ample supply of which no ship is permitted to sail on a foreign voyage. It appears to have been known as a remedy for the scurvy, far superior to all others, two hundred years ago, but seems to have been utterly neglected, till Dr Lind, more than a hundred years afterwards, revived and stated clearly its singular powers. In 1600 Commodore Lancaster sailed from England with three other ships on the 2d of April, and arrived in Saldanha Bay on the 1st of August. The commodore's crew, having each had three table-spoonfuls of lemon juice every morning, arrived there in perfect health; whereas the other ships were so sickly, that they were unmanageable for want of hands. We have all felt the commiseration and horror which the perusal of the narrative of Anson's voyage produces. His ship, the *Centurion*, left England with 400 men, of whom 200 were surviving on his arrival at Juan Fernandez, and of these eight only were capable of duty, from scurvy. Yet even this horrible catastrophe seems to have failed in rousing the nation to have recourse to a remedy so certain and efficacious. Cook was well supplied with vinegar and other acids, and found the good effects of them; but the first general supply of lemon juice to the navy was established only in the year 1795, in consequence of a trial which had been made of it the preceding year in the *Suffolk*, of 74 guns. This ship left England, and arrived at Madras in September, without touching at any land. With every man's grog there were daily mixed two-thirds of a liquid ounce of lemon juice and two ounces of sugar. She lost not a man; and though the disease made its appearance in a few, an increased dose of lemon juice immediately removed it. Thus the *Suffolk*, after a voyage of 162 days, arrived without losing a man, or having a man sick of the scurvy; whereas the *Centurion*, in 143 days from the last place of her refreshment, lost half of her crew, whilst the other half were so feeble and emaciated as to be utterly helpless. Many instances not less remarkable might be mentioned.

The abundant supply of lime juice to the squadrons employed on Arctic service was the means of averting this dreadful malady, very few cases having occurred, except in the *Investigator* (Sir Robert McClure), after being four years in the ice. The issue of preserved meats and vegetables to all ships in the Royal Navy has also doubtless tended to the health of the crews.

From the official returns collected by Sir Gilbert Blanc, M. Dupin, a French author well versed in naval subjects, has drawn out the following table, which exhibits at one view the progressive diminution of sickness, death, and desertion in the British navy, calculated on 100,000 men :—

Years.	Sick sent to Hospital.	Deaths.	Desertions.
1779	40,815	2654	1424
1782	31,617	2222	993
1794	25,027	1164	662
1804	11,978	1606	214
1813	9,336	698	10

Hence it would appear, that the diminution of sickness and of deaths has been in the proportion of 4 to 1 nearly between the years 1799 and 1813. The diminution of desertions from the hospital in the same period is not the less remarkable; and it affords, at the same time, the strongest proof of the progressive amelioration of the condition of seamen on board British ships of war. Indeed, whether on board of ship, or in any of those noble institutions the naval hospitals, which are established at all the principal ports at home, and in the colonies abroad, the attention which is paid to the sick sailor is above all praise.

The following returns, of more recent date, show the advance of medical science in this department :—

Years.	Sick Sent to Hospitals.	Dead in Hospitals.	Run from Hospitals.
1820	3,564	362	2
1830	3,137	187	2
1840	6,589	225	1
1850	9,743	309	...
1855	11,748	384	2

No wonder that 214 men should have run away from the doctors in 1804, when upwards of 1600 died in hospital out of 11,978. In 1855, out of the same number, there were only 384 deaths and 2 deserters. Can anything show more strongly the wonderful progress made in the medical department of the Royal Navy of late years?

The speedy manning of the fleet, on the first breaking out of a war, is one of the most important objects that can devolve on the naval administration, as on it alone must depend the safety of our commerce and our colonies. This has been felt at all times; and accordingly a variety of schemes have been brought forward for this purpose, but all of them have heretofore failed of success, except the compulsory mode of raising men, under the authority of press-warrants, issued by the lords commissioners of the Admiralty, by virtue of the Queen's order in Council, renewed from year to year. On the occasion of the late war with Russia, however, the fleet was manned, for the first time, without recourse to impressment. There likewise issues, on the breaking out of a war, a proclamation from the sovereign, recalling all British seamen out of the service of foreign princes or states; and commanders of all ships of war are directed to search foreign vessels for such seamen.

The impressment of seafaring men, however anomalous under a free constitution like that of Great Britain, is deemed feasible on state necessity, until it can be shown that the fleet, on an emergency, is capable of being manned without resorting to that measure. In consequence of some doubts being raised on the legality of the subject in the year 1676, when the affairs of the Admiralty were managed immediately under the direction of the King and the great officers of state, a discussion was held on this point, when it was decided by the judges and crown-lawyers, that the King had an indefeasible right to the services of his subjects when the state required them, and that the power of impressing seamen was indispensably inherent in the crown, without which the trade and safety of the nation could not be secured. The first instance of impressing men in Ireland seems to have been in the year 1678, when the lord-lieutenant received directions from the Privy Council to raise 1000 seamen for the fleet. In 1690 the lords-justices of Ireland were directed to assist the officers of the navy in impressing men in that kingdom. In 1697 a register was taken of all the seafaring men in Ireland, which amounted to 4424 men, of whom it is noted 2654 were Catholics. On several occasions, during Queen Anne's reign, the lords-justices of Ireland received directions to raise men to serve in the fleet.

In Scotland the mode of raising men by impressment was unknown before the Union; but in various instances the Council of Scotland was directed to raise volunteers for the fleet, each man to have 40s. as bounty.

In 1706 an experiment was tried for the speedy manning of the fleet, by virtue of an act of Parliament, which required the civil magistrates of all the counties to make diligent search for all seafaring men, and 20s. were allowed to the constables for each man taken up; the seamen to have pay from the day of delivery to the naval officers stationed to receive them; and if they deserted after that, they were to be considered as guilty of felony. By the same act, insolvent debtors, fit for the service, and

Personnel. willing to enter it, were released, provided the debt did not exceed L.30; and no seaman in the fleet was to be arrested for any debt not exceeding L.20. The whole proceeding under this act incurred a very heavy expense, and totally failed.

In the same year, the Queen referred to the Prince of Denmark, then lord high admiral, an address from the House of Lords, relating to the three following points:—1st, The most effectual means for manning the fleet; 2d, The encouragement and increase of the number of seamen; 3d, The restoring and preserving the discipline of the navy. His Royal Highness submitted these points to such of the flag-officers and other commanders as could be assembled, who made a report, of which the substance was to the following effect:—1st, To cause a general register to be kept of all seafaring men in England and Ireland, for which they presented the draft of a bill; 2d, That all marines qualified to act as seamen should be discharged from the army, the officers to have levy money and the men's clothing returned; 3d, That not fewer than 20,000 seamen should be kept in employ in time of peace. But they observe, that as to restoring and preserving the discipline of the navy, no particular defect being specified, they could pronounce no opinion on that head.

Discipline. The discipline of the navy, or the government of Her Majesty's ships, vessels, and forces by sea, is regulated by the act 22d Geo. II., usually known by the name of the Articles of War. By this act, the lords commissioners of the Admiralty are empowered to order courts-martial for all offences mentioned therein, and committed by any person in and belonging to the fleet and in full pay; and also to delegate the same power to admirals commanding in chief on foreign stations, which power also may devolve on his successor in case of death or recall, provided that no commander-in-chief of any fleet or squadron, or detachment thereof, consisting of more than five ships, shall preside at any court-martial in foreign parts, the officer next in command being ordered to preside thereat.

Courts-martial. By this act no court-martial can consist of more than thirteen or of less than five persons, to be composed of such flag-officers, captains, or commanders, then and there present, as are next in seniority to the officer who presides at the court-martial. And when there are but three officers of the rank of captains, the president is to call in as many commanders under that rank as will make up five in all.

Articles of War. This code of laws for the government of the fleet consists of thirty-six articles, of which nine award the punishment of death, and eleven death or such other punishment as the court-martial shall deem the offence to deserve. Those which incur the former penalty are,—the holding illegal correspondence with an enemy; cowardice or neglect of duty in time of action; not pursuing the enemy; desertion to the enemy; making mutinous assemblies; striking a superior officer; burning magazines, vessels, &c., not belonging to an enemy; murder; sodomy. The penalty of death for cowardice, or other neglect of duty, in time of action (art. 12), and of not pursuing the enemy (art. 13), was, by the 19th George III., so far mitigated as to authorize the court-martial "to pronounce sentence of death, or to inflict such other punishment as the nature and degree of the offence shall be found to deserve." Under these articles thus mitigated, Admiral Byng would probably not have been condemned to death. The other eleven articles, which leave the punishment to the discretion of the court, are,—not preparing for fight, or not encouraging the men in time of action; suppression of any letter or message sent from an enemy; spies delivering letters, &c., from an enemy; relieving an enemy; disobedience of orders in time of action; discouraging the men on various pretences; not taking care of and defending ships under convoy; quarrelling with and disobeying a superior officer in the execution of his office; wilfully neglecting the steering of ships; sleeping on watch,

and forsaking his station; robbery. The remaining sixteen articles incur the penalty of dismissal from the service or from the ship, degradation of rank, or such other punishment as the court may judge the nature and degree of the offence to deserve.

The discipline of the navy is also maintained, and greatly depends upon the strict carrying out, on the part of the commanding officers, and the observance by all others, of the regulations and instructions issued from time to time by the lords of the Admiralty, under sanction of the Queen in Council, for the government of Her Majesty's forces at sea.

The first regular code of printed instructions would appear to be that known as the Duke of York's *Sailing and Fighting Instructions*, bearing date about 1660, which formed the basis of all the subsequent ones. There have been various editions from time to time; but by far the most comprehensive, while at the same time clear and as concise as the nature of the work would admit, is that now in use, which was prepared, as we have said, in 1844, with great skill and labour, by Admiral Sir George Cockburn, than whom there never was an officer before nor since so intimately acquainted with all the duties and professional details of the service, or more anxious for its welfare. In the compilation of this important and laborious work, known as the *Queen's Regulations and Admiralty Instructions*, he was assisted by Mr Barrow. Fourteen years have now elapsed, and it is quite time,—but unhappily Sir George Cockburn is no more,—that there should be a new edition brought out, embodying all the new orders and regulations, and consequent alterations and additions. There are upwards of 300 printed circulars alone, we believe, which have been subsequently issued, independently of written orders.

Much, however, of the internal discipline of a ship of war depends upon the captain, who, being empowered to punish the men for minor offences, according to the usage of the service, courts-martial on seamen are rarely found necessary to be resorted to in well-regulated ships. In 1853 a more uniform system, defining the nature and duration of minor punishments, was promulgated by the Board of Admiralty. The principal circumstance which formerly militated against the perfect good order of the crew, was the great allowance of grog served out daily to the men, as established by order in Council, and which frequently led to drunkenness, and this again to insubordination. Perhaps half the punishments in the navy were, and still are, for this offence, which it requires the utmost vigilance and precautions on the part of the officers to prevent; but since the recent report of the committee of flag officers, which assembled in 1850, upon the question of the issue of spirits to the Royal Navy, and the diminution of the supply to one-half the quantity,—viz., from one gill to half a gill daily, with compensation in money for the remainder,—the non-issue of raw spirits (the allowance of which is now mixed with three times its quantity of water), the stoppage of it altogether to boys of second class, and the issue of it at the discretion of the captain to boys of first class,—consequent upon the report of the committee,—there has been less drunkenness in the navy and less necessity for punishment. Great credit is mainly due to Admiral Sir James Deans Dundas, for his anxiety and humane exertions in endeavouring to suppress the punishment in the fleet, in which he has thus so happily succeeded.

The greatest desire has been evinced by many boards of Admiralty, of late years (more particularly those of Sir James Graham, the Earls of Minto, Haddington, and Auckland, and of Sir Francis Baring), to improve all branches of the service, and to render the Royal Navy as attractive as possible both to officers and men. One of the most material improvements is the attention which has been paid to the education both of boys and men. Seamen's libraries have been established on a large scale, and boys' schools; and rated ships

Personnel.

Queen's Regulations and Admiralty Instructions.

ishment.

Personnel. have all got chaplains, naval instructors, and seamen's school-master appointed to them. Why sloops and small vessels should be without one or the other it is not easy to comprehend. One thing, however, yet remains to be carried out, viz., daily prayers on board every ship in the service. They are read in a few well-regulated men-of-war on some stations, and were never omitted in any one of the ships engaged in the Arctic squadron. It is not too much to say, that owing principally to this, and to there being little or no opportunity for drunkenness, no corporal punishment was ever inflicted. The practice of daily prayers on board men-of-war is of ancient date, and the omission comparatively modern. In all the earlier editions of the regulations, till that of 1810, an order for daily service will be found.

Effects of discipline.

In other respects the discipline of a well-organized ship of war is perfect; and to this discipline M. Dupin, a French writer of great sagacity, mainly ascribes the brilliant successes of the British navy, and to the want of it the ruin of that of France. "We have already cited," says he, "as a model, the management of the *matériel* of the English ships. In the preservation of this *matériel*, in the stowing it away, in the arrangement of whatever may be necessary either for manœuvres or for action, the most perfect regularity is observed. At the same time, what becoming austerity is maintained by the commanding officer; what obedience amongst the subalterns; and, in a space so limited, considering the number of men on board, and the multiplicity of movements they have to make in obeying so many different orders, what imposing silence! It is the calmness of strength, the presiding influence of wisdom. In the midst of the most complicated operations, and even in the heat and transport of battle, one hears only the words of command, pronounced and repeated from rank to rank, with a measured tone and perfect *sang froid*. No unseasonable advices, no murmurs, no tumult. The commanders meditate in silence; the word is given, and the men act without either speaking or thinking." This is remarkably so in the day of battle. Every officer and man knows precisely his place, and the duty he has to perform, on that day. By the general printed instructions, the captains of Her Majesty's ships are required to accustom the men to assemble at their proper quarters, to exercise them at the great guns, to teach them to point, fire, &c., under all circumstances of sea and weather. Indeed, it is well known that the preservation of the high character of the British navy essentially depends on the proper training of the seamen to the expert management of the guns, so as to be duly prepared in the day of battle, the issue of which so mainly depends on the cool, steady, and regular manner in which the ship's ordnance is loaded, pointed, and fired. Practice in these respects is much more necessary on board ships than on shore, as it can never happen that the ship is entirely steady, and has most frequently a rolling or pitching motion, for which allowances must be made, and which can only be made with effect by long practice.

Since 1830, when the Excellent was first established, much attention has been paid to the practice of gunnery in the Royal Navy; and all mates have to pass an examination on board that ship, which is stationed at Portsmouth for the practice of gunnery, where officers and men are instructed. They, too, pass examinations, and are appointed gunnery lieutenants and mates in the several sea-going ships; and the men are appointed seamen-gunners,—a rating of comparatively recent date. The training of seamen for landing in brigades with field-pieces has lately been adopted with great success.

Naval tactics.

If the management of the great guns of a ship of war is more difficult than the artillery of a fort, so likewise are naval tactics more difficult than those of an army; inasmuch as there is more difficulty and less dependence in placing

and directing the movements of an inanimate than an animate machine; although the recent introduction of auxiliary steam-engines in all the line-of-battle ships and frigates, and in many of the corvettes and sloops, has placed them under greater control. The general principles, however, are the same; the object of both being that of bringing the greatest possible force to bear on that point which is likely to produce the greatest possible injury to the enemy. With this view, as well as to keep a fleet together in compact order, so that straggling ships may not be cut off by the enemy, it has been found necessary to preserve a certain order of sailing, whether out of sight of an enemy or in his presence; and such an order as, according to the state of the wind and weather, and the point of bearing of the enemy's fleet, may most conveniently and expeditiously be changed into such a line of battle as the commander-in-chief may deem it most expedient to adopt in the attack to be made on his opponent. In order to do this, it is obvious that every individual captain must be able to know, under all circumstances, what the ship he commands will be able to do, in order to preserve her station in the fleet; for it is with ships as with horses, no two perhaps performing the same evolution with the same tightness of rein, or the same pressure of sail or steam. This shows the absolute necessity of a commander-in-chief frequently exercising his fleet in naval tactics, and to observe how such and such a ship will behave under a certain quantity of canvas and steam-power, and to assign her station in the line where she may appear calculated to act with the greatest efficiency. To facilitate these movements, the admirals commanding squadrons are considered as responsible for the movement of the ships in their respective divisions. They are to see that each captain strictly obeys the general order; and if any one is perceived to neglect his duty, whether belonging to his proper division or not, if in action, he has the power to send immediately another officer to suspend him. And in order that no confusion may arise, if, in time of battle, the admiral commanding in chief, or any of the admirals commanding squadrons, should be killed, his or their flags remain flying till the battle is decided. If the commander-in-chief be killed or severely wounded, a private signal is made to the second in command; or if a junior admiral be killed or wounded, the commander-in-chief is also acquainted by signal.

Since the introduction of steam, the system of naval tactics has undergone a great change, and some well-planned, well-tryed scheme of naval steam tactics is yet a desideratum. Admiral Moorsom was the first to turn attention to this subject. Happily no two steam fleets have hitherto been engaged in action, or brought into hostile collision; neither has there been any separate action with single steam-ships.

The silent method of communicating what is going on is the perfection of naval tactics; indeed it is very difficult to conceive how our ancestors contrived to manage a fleet without a code of signals. For great and important occasions, the exhibition of a flag or flags, in some particular part of the ship, might be generally understood to imply that the fleet should anchor, or tack, or form the order of sailing in two lines, or the line of battle, or some other great movement. The hoisting of a cask at the yard-arm might be understood to imply a want of water; or a hatchet, of wood; or an empty bag, of bread; and the table-cloth was a very significant invitation to dinner; but they had no means of interchanging freely their wants or intentions, or of conveying detailed intelligence. Even so late as the American war there was no established code of signals in the navy. "If an admiral," says Dr Beaton in his able *Memoirs*, "cannot command all the necessary movements of his ships by signal in the day of battle, he is not upon a footing with an enemy who possesses that advantage; and, even with better ships and better men, and more expe-

Personnel. rienced commanders, he may be foiled in his expectations of victory, if not defeated, from his want of means to direct and to perform the necessary evolutions of his fleet." "In no fight," he adds, "was the insufficiency of the present system of naval signals more conspicuous than in this (Keppel's unfortunate action); and it is to be hoped that if ever a new code be adopted for the use of the Royal Navy, it may be so clear and comprehensive, that such fatal errors as those which have been pointed out will in future be prevented." This, we may now say, has been accomplished on a plan of Sir Home Popham, which (together with Marryatt's) has rendered signals by flags as nearly perfect as they probably ever will be. Boat signals are also of the utmost importance; and the navy is indebted to Captain Wilmot for an admirable code which has recently been introduced by him, and is now in general use.

Boat signals.

Improvement in navigation.

The encouragement afforded by government to every branch of science connected with the navy, and navigation in general, has been carried much farther by England than by any other European nation, and has produced the happiest results for commercial enterprise, by determining with accuracy the precise position of ships, by shortening long voyages, and by the discovery of new lands and unexplored regions. The name of Admiral Sir Francis Beaufort, who was for many years hydrographer of the Admiralty, and has recently departed this life, will ever hold a prominent position in the naval annals of England as one who, in his generation, rendered the utmost service, not only to his profession, but to the navy and marine of all nations, by the extreme care and accuracy with which the numerous charts published under his immediate superintendence have been issued to the world, embracing elaborate surveys in all parts of the globe. From the commencement of the eighteenth century, when a national reward was first offered to the man of science, or the artist, who should discover a method sufficiently exact to determine the longitude of a ship's place at sea, to the present time, the improvements

in the construction and division of all kinds of instruments for measuring angles, in the calculations of lunar and other tables, and, above all, in the manufacture and adjustments of chronometers, have continued in gradual progression, and may now be considered as having arrived at such a degree of perfection, more especially the chronometers, that the discovery of the longitude can scarcely be said to remain a desideratum. We may form an idea what the progress in the improvement of chronometers has been, when a reward was offered by Parliament in the year 1814, to the first who should determine the longitude at sea *within a degree*; and in 1820, three chronometers, after remaining in the arctic regions for 18 months, returned to England without altering their rates more than a few seconds of time.

The officers of the Royal Navy are now much more generally versed in the sciences than they were in former years. In fact, it is now necessary for a young man to be well acquainted with a certain portion of mathematical and astronomical knowledge to enable him to pass an examination, without which he cannot be qualified for the commission of a lieutenant. Lord Auckland, desirous of encouraging a taste for scientific pursuits, caused a valuable scientific manual to be drawn up in the year 1847, and issued to the fleet. The examinations also of the several warrant-officers, and their qualifications for their respective stations, are more strictly attended to than formerly.

The encouragement given to the navy from its first regular establishment has marked it as a favourite service in the minds of the public. The sea-pay, the half-pay, and other emoluments, have generally been superior to those enjoyed by the army, but subject to great fluctuations in every reign, and to frequent changes in the same reign.

The following table will exhibit, at one view, the complete war establishment of officers and non-commissioned officers, seamen, and marines, on board every class of Her Majesty's ships, with the rate of pay now granted to each, as established by order in Council:—

Full Pay of the Royal Navy.

N.B.—Corporals, Fifers, or Drummers, Bombardiers and Gunners, who obtain Good Conduct Badges, are allowed additional pay according to the regulated scale.

Establishment of half-pay.

Though the navy, as we have seen, was put upon a regular establishment under the reign of Henry VIII., neither officers nor seamen received any pay or emolument in time of peace until the reign of Charles II., when in 1668 certain allowances were made to flag-officers and their captains out of the L.200,000 a year voted for the whole naval service; and in 1674 certain other allowances were granted, by order in Council, to captains who had commanded ships of the first and second rates, and to the second captains to flag-officers, on the ground, as assigned in the preamble, that they had undergone the brunt of the war, without sharing in the incident advantages of it, as prizes, convoys, and such like, which the commanders of the smaller classes of ships had enjoyed. But the first regular establishment of half-pay for all flag-officers, captains, first-lieutenants, and masters, was by King William,

in the year 1693, provided they had served a year in their respective qualities, or had been in a general engagement with the enemy. A regularly-established half-pay was further sanctioned by an order in Council of Queen Anne in 1700, the conditions of which were, that no officer should enjoy the benefit thereof who had absented himself without permission of the Lord High Admiral or lords commissioners of the Admiralty, or who had been dismissed for any misdemeanour, or by court-martial, or who had not behaved himself to the satisfaction of the Lord High Admiral, or who should have leisure to go out of his Majesty's dominions, if employed in the merchant service or otherwise, or who enjoyed the benefit of any public employment. Since the above period the rate of half-pay to the several officers of the navy has undergone various modifications. At present it stands thus:—

Rates of Half-Pay at present established for the Navy and Marines.

FLAG OFFICERS.			
	Per Annum.	Per Diem.	
Admirals of the Fleet	L.149 15 0	L.3 3 0

RATES OF PENSION TO BE GRANTED TO INSPECTORS OF MACHINERY AFLOAT, AND TO ENGINEERS OF THE ROYAL NAVY.							
(Under Her Majesty's Order in Council of 13th June 1853.)							
To an inspector of machinery afloat, provided he shall have served upwards of five years in that rank, a pension of from L.160 to L.180 per annum.							
If an inspector of machinery afloat be found unfit prior to completing five years' service in that rank, the time so served shall be added to his service as chief engineer, and he shall be pensioned on the scale for chief engineers.							
To a chief engineer, having served twelve years as a chief engineer, and being in the first class, a pension of L.110 to L.130 per annum; having served six years as a chief engineer, and being in the first or second class, a pension of from L.85 to L.105 per annum; having served five years as an engineer in the Royal Navy, three of which as a chief engineer, a pension of from L.75 to L.90 per annum.							
If a chief engineer be found unfit prior to completing three years in that rank, the time so served shall be added to his service as assistant-engineer, and he shall be pensioned on the scale for an assistant-engineer.							
To an assistant-engineer, having served as such twenty years in the Royal Navy, and being in the first class, a pension of from L.65 to L.75 per annum; having served as such ten years in the Royal Navy, and being in the first or second class, a pension of from L.50 to L.60 per annum; having served as such three years in the Royal Navy, a pension of from L.40 to L.50 per annum.							
The time served by assistant-engineers as engineers on the old establishment shall be reckoned as if the same had been served as assistant-engineers.							
CHAPELAINS.							
After 8 years' service at sea		L.91 5 0	L.0 5 0				
After 10 " " under New Regulations		91 5 0	0 5 0				
For each year's longer service than 8 at sea, 6d. per diem additional till it reach		182 10 0	0 10 0				
CHAPELAINS AND NAVAL INSTRUCTORS.							
After 15 years' service, one half of the highest rate of half-pay of naval instructors, in addition to the half-pay to which they may be entitled as chaplains.

" 15 "		91 5 0	0 5 0				
" 20 "		127 15 0	0 7 0				
(Payable Quarterly.)							

Personnel. vessels under a flag or flags, the like regulations as to the apportionment of the flag share to the flag-officer or officers are to be observed.

With reference to flag-officers it is to be noted:—

That when an inferior flag-officer is sent to reinforce a superior officer on any station, the superior flag-officer shall not share in any prize taken by the inferior flag-officer before he has arrived within the limits of that station, unless the inferior officer shall have received some order directly from, and shall be acting in execution of, some order issued by, such superior flag-officer.

No chief flag-officer quitting any station, except upon some definite urgent service, and with the intention of returning to the station as soon as such service is performed, shall share in any prize taken by H.M.'s ships or vessels left behind after he has passed the limits of the station, or after he has surrendered the command to another flag-officer appointed by the Admiralty to command in chief upon such station.

An inferior flag-officer quitting any station (except when detached by orders from his commander-in-chief upon a special service, accompanied with orders to return to such station as soon as the service has been performed) shall have no share in prizes taken by the ships and vessels remaining on the station after he has passed the limits thereof.

In like manner flag-officers remaining on such station shall not share in the prizes taken by such inferior officer, or by ships or vessels under his immediate command, after he has quitted the limits of the station, except he has been detached as aforesaid.

A commander-in-chief or other flag-officer belonging to any station shall not share in any prize or prizes taken out of the limits of that station by any ship or vessel under the command of a flag-officer of any other station, or under orders from the commissioners of the Admiralty, unless such commander-in-chief or flag-officer is expressly authorized by the said commissioners to take the command of that station in which the prize or prizes is or are taken, and shall actually have taken upon him such command.

Every commodore having a captain under him shall be esteemed a flag-officer with respect to the twentieth part of prizes taken, whether he be commanding in chief or serving under command.

The first captain to the admiral and commander-in-chief of the fleet, and also the first captain to any flag-officer appointed to command a fleet of ten ships of the line or upwards, shall be deemed to be a flag-officer for the purpose of sharing in prize, and shall be entitled to share therein as the junior flag-officer of such fleet.

Any officer on board any ships of war at the time of capturing any prize or prizes who shall have more commissions than one, shall be entitled only to share in such prize or prizes according to the share allotted to him by the above-mentioned distribution, in respect to his superior commission or office.

And with reference to other officers it is to be noted, That a captain, commander, or other commanding officer of a ship or vessel, shall be deemed to be under the command of a flag when he shall have received some order from, or be acting in the execution of some order issued by, a flag-officer, whether he be or be not within the limits of the station of such flag-officer; and in the event of his being directed to join a flag-officer on any station, he shall be deemed to be under the command of such flag-officer from the time when he arrives within the limits of the station, which circumstance is always to be carefully noted in the log-book; and it shall be considered that he continues under the flag-officer of such station until he shall have received some order directly from, or be acting in the execution of some order issued by some other flag-officer, duly authorized, or by the Lord High Admiral, or the commissioners for executing the office of Lord High Admiral

Personnel. The captain, commander, lieutenant commanding, master commanding, or any other officer duly commanding, any ship, sloop, or vessel of war, singly taking any prize from the enemy,—that is to say, the officer actually in command at the time,—shall have one-eighth of the remainder, or if there is no flag, one-eighth of the entire net proceeds; except that, if the single capturing ship be a rated ship, having a commander under the captain, the commander shall take a portion of the one-eighth part, as if he were commander of a sloop, according to the proportion hereinafter set forth; and if more than one commanding officer of the same rank of command shall be entitled to share as joint captors, the one-eighth shall be equally divided between them; but when captains, commanders, lieutenants commanding, and masters commanding, respectively, H.M.'s ships and vessels of war, and commanders under captains in rated ships, shall share together, in whatever variety of combination, the one-eighth shall be so divided into parts for a graduated apportionment as to provide for each captain receiving six parts, each commander of a sloop, or commander under a captain in a rated ship, three parts, and each lieutenant commanding, or master commanding, or other officer actually commanding, a small vessel of war, two parts; commodores of the second class, and field-officers of marines, or of land forces serving as marines, doing duty as field officers, above the rank of major, to share as captains; and field officers of marines, or of land forces serving as marines, and doing duty in the rank of major, to share as commanders of sloops.

After provision shall thus have been made for the flag share (if any), and for the portion of the commanding officer or officers, and others as above specified, the remainder of the net proceeds shall be distributed in ten classes, so that each officer, man, and boy, composing the rest of the complements of H.M.'s ships, sloops, and vessels of war, and actually on board at the time of any such capture, and every person present and assisting, shall receive shares, or a share, according to his class, as set forth in the following scale:—

First Class.—Master of the fleet, inspector of steam machinery afloat, when embarked with a fleet, medical inspector, or deputy medical inspector, when embarked with a fleet, forty-five shares each.

Second Class.—Senior lieutenant of a rated ship, not bearing a command under the captain, secretary to the admiral of the fleet, or admiral commanding in chief, thirty-five shares each.

Third Class.—Sea lieutenant, master, captain of marines, of marine artillery, or of land forces doing duty as marines, whether having higher brevet rank or not, secretary to an admiral or to a commodore of the first class not commanding in chief, chief engineer, twenty-eight shares each.

Fourth Class.—Lieutenant or quarter-master of marines, lieutenant of marine artillery, lieutenant, quartermaster, or ensign of land forces doing duty as marines, secretary to a commodore of the second class, chaplain, surgeon, paymaster, naval instructor, mate, assistant-surgeon, second master, assistant-paymaster in charge, assistant-engineer, gunner, boatswain, carpenter, eighteen shares each.

Fifth Class.—Midshipman, master's assistant, pilot, clerk (not passed), master-at-arms, chief gunner's mate, chief boatswain's mate, chief carpenter's mate, chief captain of the forecabin, admiral's coxswain, chief quartermaster, seamen's schoolmaster, ship's steward, ship's cook, ten shares each.

Sixth Class.—Naval cadet, clerk's assistant, captain's coxswain, ship's corporal, quartermaster, gunner's mate, boatswain's mate, captain of the forecabin, captain of the after-guard, captain of the hold, captain of the maintop, captain of the foretop, coxswain of the launch, sailmaker, ropemaker, caulker, leading stoker, blacksmith, sergeant of marines, of marine artillery, or of land forces doing duty as marines, nine shares each.

Seventh Class.—Captain of the mast, captain of the

Personnel. mizen-top, yeoman of the signals, coxswain of the barge, coxswain of the pinnace, coxswain of the cutter, second captain of the fore-castle, second captain of the maintop, second captain of the foretop, second captain of the afterguard, sailmaker's mate, caulker's mate, musician, cooper, armourer, corporal of marines or of land forces doing duty as marines, bombardier of marine artillery, head krooman, six shares each.

Eighth Class.—Leading seaman, shipwright, second captain of the hold, able seaman, carpenter's crew, sailmaker's crew, cooper's crew, armourer's crew, yeoman of the store-rooms, steward's assistant, ordinary seaman, blacksmith's mate, private and fifer of marines, or of land forces doing duty as marines, gunner of marine artillery, painter, stoker, coal trimmer, second head krooman, sick-berth attendant, bandsman, tailor, butcher, three shares each.

Ninth Class.—Cook's mate, ship's steward's boy, admiral's domestic, superintendent's domestic, admiral's steward and cook, captain's steward and cook, ward-room and gun-room steward and cook, subordinate officer's steward and cook, commander's servant, secretary's servant; second class ordinary seaman, assistant stoker, barber, boy of the first class, first and second class krooman, supernumeraries, except as hereinafter provided, persons borne merely as passengers, and not declining to render assistance on occasion of capture, two shares each.

Tenth Class.—Boy below the first class, one share.

All supernumeraries holding ranks in the service above the ranks or ratings specified in the fifth class, who have been ordered to do duty in any of H.M.'s ships or vessels by the Lord High Admiral, or by the commissioners for executing the office of Lord High Admiral, by the senior officer of the fleet or squadron; or, if none senior, then by the captain or commanding officer of the capturing ship or vessel, if not by special authority employed in higher capacities, shall share according to the rank which they respectively hold in the service; but in all cases to qualify them for so sharing, and not merely as supernumeraries in the ninth class, due notation of their being thus respectively ordered to do duty must have been made on the muster-books.

With respect to supernumeraries of ratings in the service below the denominations of those specified in the fourth class, who, at full victuals, are engaged in the ordinary duties of the ship, they shall share according to their ratings.

When any capture is made from the enemy, the captains or commanding officers of H.M.'s ships or vessels of war making the same shall transmit, or cause to be transmitted, as soon as may be, to the secretary of the Admiralty a true and perfect list of all the officers, seamen, marines, soldiers, and others, who were actually on board on the occasion, accompanied by a separate list, containing the names of those belonging to the crew who were absent on duty or otherwise at the time, specifying the cause of such absence, each list to contain the quality of the service of each person.

Conveyance of Treasure.—Scale of Rates.

	For Crown Treasure.	For Treasure belong- ing to other Parties.	
		Peace and War.	
		Gold or Jewels.	Silver.
	Per cent.	Per cent.	Per cent.
Between any two ports, the navi- gable distance between which shall not exceed six hundred leagues.....	2	2	1
Between any two ports, the navi- gable distance between which shall exceed six hundred leagues, and shall be less than two thousand leagues.....	1	1½	1½
For any distance of two thousand leagues and upwards.....	1	1½	2

The above rates are payable clear of all deduction whatsoever; and it is to be stipulated in the bill of lading that the captains and commanding officers of H.M.'s ships and vessels shall not be liable to any expenses attending the shipment of such treasure, or other articles, until the same shall be safe alongside of their respective ships or vessels, and that their liability shall cease from the moment they shall have landed the treasure at the port to which the ships carrying the treasure shall be destined.

Another great encouragement for young men to enter the naval service arises from the honours bestowed by the sovereign for any brilliant exploit. Thus, in consequence of the skill and bravery which were exhibited in the great and glorious action of the 1st of June 1794, his Majesty was graciously pleased to confer on Earl Howe the order of the garter; Admirals Graves and Sir Alexander Hood were made barons of the kingdom of Ireland; and Rear-admirals Bowyer, Gardner, and Pasley, together with Sir Roger Curtis, captain of the Queen Charlotte, were created baronets. Gold medals and chains were also distributed to such admirals, and gold medals to such captains, as were particularized in Lord Howe's despatches. The first lieutenants of each ship were promoted to the rank of commanders; and pensions of L.1000 per annum were granted to Rear-admirals Bowyer and Pasley, in consideration of the loss of limbs.

For the action of the 14th of February 1797, Lord St Vincent was advanced to the dignity of an earl, and a pension was granted to him of L.3000 a-year; Vice-admirals Thompson and Parker were created baronets; Commodore Nelson received the order of the bath, and Captain Calder of the Victory the honour of knighthood; and gold medals were distributed to the admirals and captains.

For the action of the 11th of October 1797, Admiral Duncan was created a viscount, with a pension of L.2000 a-year; Vice-admiral Onslow was made a baronet; and Captain Fairfax had the honour of knighthood. Gold medals were also distributed to the admirals and captains.

For the action of the 1st of August 1798, his Majesty was pleased to testify his sense of the importance of this brilliant achievement by raising Sir Horatio Nelson to the dignity of the peerage, by the title of Baron Nelson of the Nile, and by directing medals to be distributed to the captains. The first lieutenant of the *Majestic* was made a captain, and the first lieutenants of the other ships were promoted to the rank of commanders; and for the attack of the Danish fleet at Copenhagen, Lord Nelson was raised to the dignity of a viscount, and the order of the bath was conferred on Admiral Graves.

For the ever memorable action of Trafalgar, in which Lord Nelson fell in the arms of victory, his Majesty was pleased to confer upon his brother the rank of earl, with a pension of L.5000 a-year, and the sum of L.120,000 was voted by Parliament for the purchase of an estate to be annexed to the title; Admiral Collingwood was raised to the dignity of baron, Lord Northesk was honoured with the order of the bath, and Captain Hardy was created a baronet; the captains received medals, five lieutenants were made captains, and twenty-four commanders; twenty-two midshipmen were made lieutenants, and the senior captain of marines was made brevet-major.

By this last act of Lord Nelson's life was annihilated the only remaining hope of the combined navies of France and Spain, and a blow given to the naval power of the enemies of Great Britain, which they never recovered during the remainder of the war.

In the secondary victories of Sir John Warren, Sir John Duckworth, Sir Robert Calder, Sir Richard Strachan, Lord Gambier, and Lord Exmouth, and even for brilliant actions of single ships, appropriate distinctions have never been with-

Personnel

Honours
and re-
wards.

Personnel. held. Exclusive of peerages and baronetcies, the honours bestowed for gallant conduct in the naval service at present consist of six knights grand crosses of the military Order of the Bath, thirty-three knights commanders, and 114 companions of the Bath. In addition to these, there are of the civil Order of the Bath one cross, two knights commanders, and three companions.

Medals have also been granted of late years by the Queen for various naval services, and distributed alike to the officers, seamen, and marines. These consist of the war medal for actions in ships and boats from 1793 to 1815; the medal for Algiers, Navarino, Acre, and Syria; the Burmese, China, and Kafir medal; and, lastly, the medal for services performed in the Arctic seas, which have greatly added to the renown of the British navy, have led to vast discoveries in that interesting portion of the globe, solving the problem of the N.W. passage, which for three centuries engaged the attention of the maritime nations of Europe, and rendering illustrious the names of many officers. Conspicuous among these in our naval annals will ever stand the names of Franklin, Parry, Ross, Collinson, and McClure, while those of Scoresby and Penny will be scarcely less conspicuous in the mercantile marine. The institution of the Order of Valour will be another incentive to the officers and men of the Royal Navy in the performance of heroic deeds in their country's service. There are at present twenty-five officers, seamen, and marines, recipients of the Victoria Cross. In addition to the foregoing there are many officers and seamen authorized to wear foreign orders—the Legion of Honour, the Royal Hanoverian Guelphic Order, the orders of St Michael, St George, the Tower and Sword, Redeemer of Greece, the Medjedic, &c.

Naval aides-de-camp to the Queen. Amongst the honours bestowed by the sovereign upon officers of the navy and Royal Marines is the appointment of aides-de-camp to the Queen. Of these there are twelve: one of them, the first and principal, is an admiral, ten are captains, and two colonels of marines.

Good-service pensions. Good-service pensions are also awarded to a certain number of flag-officers, captains, and field-officers of marines. These are selected according to their standing, length and nature of services, a statement of which is given, in each case, in the annual naval estimates presented to Parliament. There are at present seven flag-officers and twenty-one captains of the Royal Navy, and three field-officers of the Marines, in receipt of the good-service pension.

Pensions for wounds. The provision which is made for officers, in the event of losing a limb, or being so severely wounded in the service that the prejudice to the habit of body is equal to the loss of a limb, is another encouragement for entering the naval service. There are at present 173 officers to whom pensions for wounds have been granted.

For an admiral, from L.300 to L.700 per annum.

A captain, wounds 250 0; loss of a limb, L.300 0

Commander 150 0; 200 0

Lieutenant 91 5; 91 5

Marine officers the same as in the army.

Widows' pensions. A provision is likewise made for the widows of the commission and warrant officers of the royal navy, and voted annually on the navy estimates. The pensions are allowed according to the annexed scale, being similar, in most cases, to the widows of officers in the army of corresponding ranks. The latter are also provided for by an annual vote of Parliament.

Rules and Orders for granting Pensions to the Widows of Commission and Warrant Officers of the Royal Navy.

Art. 1.—Widows of commission and warrant officers of the Royal Navy may be allowed pensions as hereinafter directed, and subject to the following restrictions, provided they shall appear to the lords commissioners of the Admiralty to be proper and de-

serving objects of the public bounty, and not left in wealthy circumstances.

Art. 2.—The rates of pensions shall be as follows, viz:—

* If the officer was killed in action, or died within six months of wounds received in action.

† If the officer was drowned, or suffered other violent death in an immediate act of duty, or if it shall be proved to the satisfaction of the lords commissioners of the Admiralty that he has died from the effects of any injury or disease caused by extraordinary exposure or exertion on service within six months after his being first certified to be ill.

Personnel.

PENSIONS TO THE MOTHERS AND SISTERS OF OFFICERS
KILLED IN ACTION.

Mothers.—Where an officer is killed in action, and leaves no widow nor legitimate child, but leaves a mother who is a widow in distressed circumstances, and who was dependent upon him, the mother shall receive a pension equal to the ordinary rate of widow's pension attached to the rank which her son held at the time of his death; but if such mother shall herself be in receipt of a pension as an officer's widow, or shall have any other provision of any kind from the public, in that case no allowance will be made to her on account of her son, unless she gives up the other pension or allowance; and the pension given to a mother on account of her son will be forfeited on re-marriage.

Sisters.—The allowance made to the sisters of officers is not to exceed that which would be given to a mother, and will not be given in any case unless the officer shall have fallen in action, or shall die of wounds received in action, within six months after being wounded, and shall have left no widow, legitimate child, nor mother, nor unless the sister shall be an orphan, having no surviving brother, and shall have been dependent for support upon the officer killed. Every pension so granted will cease when the person receiving it shall marry, or be otherwise sufficiently provided for.

The widows of boatswains, gunners, and carpenters of the royal navy, and masters of naval vessels, appointed prior to the 30th of June 1830, will, if otherwise qualified, be entitled to a pension of L.25. Widows of the above warrant-officers, and the widows of engineers who shall have been warranted *subsequently* to the 30th June 1830, are not entitled to pensions unless their husbands shall have suffered a violent death, and provided they shall be otherwise entitled to the same, in which case the following pensions will be allowed:—

Art. 1.—To the widow of a gunner, boatswain, carpenter, or engineer, whose husband shall have been killed in action, a pension of L.35 a year.

Art. 2.—To the widow of any of the above-named warrant-officers, whose husband shall have been drowned on duty, or suffered a violent death in an immediate act of duty, a pension of L.30 a year.

Art. 3.—The pensions of all widows shall commence from the first day of the month following that in which their husbands died, provided application be made by the widow within twelve months from the same, otherwise from the time only of such application; and all applications for pensions must be addressed to the Secretary of the Admiralty.

Art. 4.—The widows of officers (except chaplains) who shall have married after the 31st of December 1830, are only entitled to the pensions of their respective classes in the event of their husbands having been on the list of commission or warrant officers, or on the list of naval instructors, ten complete years, except the husband be killed in action, or lose his life in the execution of the service.

Art. 5.—No widow shall receive a pension as a chaplain's widow, unless her husband shall have been in priest's orders, nor unless his name was on the list at the time of his death, nor unless she shall have been married during, or prior to, her husband's service in the navy, and unless her husband shall have served three years on full pay subsequent to their marriage, and shall have served the length of time to entitle him to his half-pay.

Art. 6.—No widow shall be entitled to the pension who has not been married twelve months to the officer by whose right she claims the same, unless the said officer was *killed* or *drowned* in the sea service; but the lords commissioners of the Admiralty may grant the pension, in such cases as they think proper, when officers die before the expiration of twelve months from the time of their marriage.

Art. 7.—If any officer shall marry after the age of sixty years, his widow shall not be entitled to receive the pension; or, if being capable of service, he should, at his own solicitation, be excused from it, being at the time warned that his widow would thereby forfeit the pension.

Art. 8.—The above pensions shall not be received by any widow together with any other pension from the government.

Art. 9.—Widows who shall have re-married after the 31st December 1830 shall forfeit their pensions.

Art. 10.—The pensions of widows who shall have re-married prior to the 31st of December 1830 shall be paid to themselves, and their receipts shall, notwithstanding their coverture, be deemed a sufficient discharge for the payment of their pension.

Besides these pensions, there has been established a Compassionate Fund, for the relief of such widows and orphan children as may appear to be proper objects of compassion. The sums annually required are voted by Parliament, and at present are limited to L.16,000 a year. One of the greatest benefits that could be conferred upon the

Royal Navy would be to double the vote for the Compassionate Fund, which is quite inadequate for the object intended, and admits of very little compassion being shown to the orphan children of officers who have faithfully served their country.

Pensions to petty officers and seamen are granted by the Board of Admiralty for wounds, infirmities, and length of service; and the sum required for this purpose is voted annually on the navy estimates.

In addition, however, to the pensions granted for wounds, and the pensions and compassionate allowances secured to the widows and children of officers, there are happily other provisions made for them by charitable institutions,—for instance,

Naval Knights of Windsor, formerly called *Poor Knights*. Naval —There is an asylum afforded at Windsor, by the will of Knights of the late Samuel Travers, Esq., for seven "superannuated or disabled lieutenants of English men-of-war, who are to be single men, without children, inclined to lead a virtuous, studious, and devout life; and to be removed if they give occasion for scandal." One of these, the senior officer, is appointed governor of the institution.

Queen Adelaide's College at Penge was established by Queen her late Majesty for the widows of twelve officers of the Adelaide's ranks of lieutenant, master, surgeon, and paymaster. Each College. widow is allowed L.30 per annum, with coals and candles. The nominations are in the gift of the First Lord of the Admiralty.

The Royal Naval Benevolent Society, established in The Royal 1739. It affords relief to officers (being subscribers) of Naval Benevolent and above ward-room rank, and to their widows and families under misfortune and distress. The scale of subscription Society. entitling to relief is so small that all officers would do well to support it. The following is the scale, viz.:—Flag-officers—annual, 1, 2, and 3 guineas; life, L.20. Captains, commanders, inspectors of hospitals and fleets, and secretaries—annual, 10s. 6d.; life, L.10. Chief engineers—annual, 6s.; life, L.6. Ward-room officers (including assistant-surgeons who are entitled to ward-room rank, and naval instructors)—annual, 5s.; life, L.5. It appears by the report that many cases have occurred where the widows, orphans, or other relatives entitled, have received hundreds of pounds for the husband's subscription of as many shillings. Thus, the sister of a deceased captain, for four years' subscription of L.1, 1s., received for his L.4, 4s. the sum of L.530. The orphans of a master, for six years' subscription of 5s., received for his L.1, 10s. the sum of L.182, 8s. A lieutenant, with eight children, for twenty years' subscription of 5s., received prior to his death L.170; and subsequently his widow the sum of L.88; and many other similar cases might be mentioned.

Queen Adelaide's Naval Fund.—This fund was estab-Queen lished in 1850 for the relief of the orphan daughters of Adelaide's officers of the Royal Navy and Marines. The dividends Naval arising from donations and subscriptions are entirely appro- Fund. priated to the relief of orphans, who are assisted by pecuniary grants bestowed at the discretion of the committee, and available either for the education of the young, the maintenance of the aged, or the casual assistance of those in temporary difficulty.

The Royal Naval School at New Cross, Kent, incor- The Royal porated by Act of Parliament 1840, has been established a Naval quarter of a century. The annual charge for board and School. education of the sons of naval and marine officers of ward-room rank is L.30, some are admitted at L.25, a limited number gratuitously, and at L.15 a year, according to the necessitous circumstances of the parents, a preference being given to orphans of those who may have fallen in the service of the country. A limited number of pupils, not being sons of naval or marine officers, are admitted on payment of L.50 per annum. Several young officers who

Personnel. were educated at this school distinguished themselves in the late war with Russia, and particularly so in the recent Arctic expeditions in search of Sir John Franklin and the crews of H.M. ships Erebus and Terror.

Royal Naval Female School. *The Royal Naval Female School*, formerly at Richmond, and now St Margaret's, Isleworth, was established in 1840, for the purpose of bestowing upon the daughters of *necessitous* naval and marine officers, of and above the rank of ward-room officers, a good, virtuous, and religious education at the lowest possible cost. It owes its origin to the late Admiral Sir Thomas Williams, G.C.B., who invested L.1000 in trust; and by an additional contribution of L.100 per annum for seven years, arranged payments of the rents for that period. The Patriotic Fund made last year (1857) a grant of L.5000 to the institution. There are now 87 daughters of officers in the school; of these 26 are received at the annual payment of L.40; 56 (all daughters of *necessitous* officers) are boarded and educated at the entire cost to the parents or guardians of L.12 per annum; and 5 are nominees of the Patriotic Fund, whose fathers died during the late war with Russia, the establishment defraying the *larger* amount of actual cost through the means of voluntary contributions. Of the number of pupils on the reduced scale of payment, 5 have lost both parents, and 35 others have lost their fathers.

Orphan schools for seamen's children. Neither are there wanting charitable institutions for the orphan children of seamen and marines at the several ports; and the recent establishment of sailors' homes for men-of-war's men and merchant seamen, at most of the ports throughout the United Kingdom, is one of the greatest boons that could have been conferred. It is impossible to speak too highly of those zealous and humane officers through whose exertions they have been established, more especially the late Captain Robert Elliot, who devoted the whole of his time and private resources on the first sailors' home that was opened in Wells Street, London; and the present Captain William H. Hall, C.B., who has been most indefatigable at every port in the kingdom. The late Sir Edward Parry was another zealous supporter of the sailors' homes, and of all institutions which had for their object the eternal as well as the temporal welfare of the British seaman. To his illustrious name must be added those of Admiral Bowles, the late Sir Francis Beaufort, the Hon. F. Maude, of Captain Gambier, and of many other well-known officers, who have also zealously devoted themselves to the object.

These various institutions are now countenanced, and in some cases aided, by the government, by whom annual grants are made both to the orphan schools and sailors' homes. It would be well if these grants were made upon a more liberal scale.

Greenwich Hospital. The establishment of *Greenwich Hospital* embraces much more extensive objects than any of the foregoing. The first idea of this noble institution,—the glory and ornament of the kingdom, which it is to be hoped that the restless spirit of innovation will leave untouched,—has been ascribed, with every appearance of justice, to Mary, the consort of William III. Being desirous that our gallant seamen, worn down by age or infirmities, as well as suffering from wounds, should not be left destitute, she made a grant, jointly with King William, of the palace of Greenwich, and of certain lands adjoining, to be appropriated to this purpose, in order, as stated in the king's commission, to “the making some competent provision, that seamen who, by age, wounds, or other accidents, shall become disabled for further service at sea, and shall not be in a condition to maintain themselves comfortably, may not fall under hardships and miseries, but may be supported at the public charge, and that the children of such disabled seamen, and also the widows and children of such seamen as shall happen to be slain in sea service, may, in some reasonable manner, be provided for and educated.” In 1695 the committee appointed to examine and report

Personnel. on the premises recommended an additional wing to King Charles's building, which being approved by the king, Sir Christopher Wren undertook to superintend the new erections without any pay or reward. Since that time various additions and improvements have been made to this magnificent pile of building, which was completed, very nearly as it now appears, in the year 1778.

The king granted L.2000 a year, towards the carrying on, perfecting, and endowing of this hospital. The great officers of state and wealthy individuals also subscribed liberally to the undertaking. It was at the same time enacted by Parliament, that a deduction of sixpence per man per month should be made out of the wages of all mariners for the use of the hospital; and power was given to the Lord High Admiral to appoint commissioners for receiving the said duty, whose office is situated on Tower Hill. These deductions no longer exist, and the establishment has been broken up. In 1699 his Majesty contributed the sum of L.19,500, being fines laid by the House of Lords on certain merchants convicted of smuggling. In 1705 Queen Anne assigned to the use of the hospital the effects of Kid the pirate, amounting to upwards of L.6000. In 1707 Robert Osbaldiston, Esq., devised by will half of his estate, which was valued at L.20,000. In the same year Anthony Bowyer gave the reversion of a considerable estate for the use of the hospital. By several statutes the forfeited and unclaimed shares of prize-money were given to the hospital, and various grants from time to time continued to be made by Parliament. But the most substantial grant was that made by the Commons of the rents and profits of the forfeited estates of the Earl of Derwentwater, amounting at that time to about L.6000 a year, and at present to the gross rental of L.60,000, of which, after payment of all expenses for improvements, repairs, collections, and incumbrances, the annual receipt may be estimated at from L.30,000 to L.40,000.

At present the permanent revenues of the hospital consist of the following heads:— **Permanent revenues.**

1. The duties arising from the North and South Foreland lighthouses.
2. The rents and profits of the Derwentwater estates, including the lead mines.
3. Rents of the market of Greenwich, and of certain houses there and in London.
4. Interest of money invested in the public funds.
5. Forfeited and unclaimed shares of prize-money
6. Fines for various offences.

It is evident that the funds of the establishment must vary considerably in times of war and peace; being lowest in the latter period, when the demands are heaviest upon it, especially for a certain number of years after the close of a war.

The rental of the estates belonging to the hospital in the counties of Northumberland, Cumberland, and Durham, rose from L.23,000, in 1805, to L.43,000, in 1816. The present gross rental of these estates and the lead mines, as above stated, amounts to about L.60,000; the North and South Foreland lights to L.7000; and the interest of funded property to L.50,000; making, with other contingencies, an annual revenue of about L.150,000, the whole of which is expended on the household establishment, the clothing, maintenance, and allowances to pensioners and other attendants, with repairs, taxes, and contingencies.

The establishment of this noble institution consists of a military and civil department. In the former there is a **Hospital establishment.** governor, who is a flag-officer in the navy, lieutenant-governor, who is also a flag-officer, four captains, four commanders, eight lieutenants, and two masters; two chaplains, two physicians, five surgeons, and two dispensers,—all resident within the hospital. In the latter there are

Personnel. five civil commissioners, two of whom are *now* naval officers; a secretary and his assistant, a cashier, steward, clerk of the check,—each of whom has his chief clerk; an architect, and two inspectors of works, with their clerk. The number of in-pensioners is about 3000, and the number of nurses 180, all of whom must be the widows of seamen of the navy, and under the age of forty-five years at the time of admission.

Pensioned officers on Greenwich Hospital. Under the naval administration of Earl Grey the following officers were added to the out-pensions of Greenwich Hospital, to be selected by the Admiralty according to their respective claims on the service:—

	Per Year.
10 Captains at.....	L.80
15 Commanders at.....	60
50 Lieutenants at.....	50
In addition to their half-pay.	

Out-pensioned seamen. The out-pensions to seamen were first established in the year 1763, by act of 3d Geo. III., c. 16, in consequence of which 1400 out-pensioners were appointed at L.7 per annum each, after undergoing an examination at the Admiralty as to their claims.

At the close of the long revolutionary war the applications became so numerous, and the claims of the seamen who had been wounded or worn out in the service so strongly grounded in humanity and justice, that it became necessary to adopt a scale of pensions, and to establish certain rules and regulations, by which seamen of Her Majesty's fleet and Royal Marines should be remunerated for wounds or hurts, debility, and length of service. The following are the present regulations:—

For Wounds, Hurts, or Debility.

Every seaman, landman, boy, or royal marine, wounded or hurt in Her Majesty's service, is entitled to a pension proportioned to his wounds or hurts, of not less than sixpence a day, and not more than one shilling and sixpence or two shillings a day. For sickness or debility, after seven years' service, and under special circumstances before that period, of not less than fivepence a day, nor more than tenpence, according as he may appear capable of assisting himself. Beyond fourteen, and less than twenty-one years' service, not less than eightpence, nor more than one shilling and threepence. And after twenty-one years' service, one shilling and sixpence a day. But the rates are altered from time to time.

All the above-mentioned pensions may be forfeited by misconduct, by desertion, and by sentence of a court-martial; also by neglecting or omitting to attend at such port or place, and at such time, as shall, in time of war or in prospect of a war, be appointed for the assembling of the pensioners, by the lords commissioners of the Admiralty.

In 1853 a committee of naval officers was appointed to consider the whole subject of manning the navy and granting pensions to seamen. Upon their recommendation, all boys entering the navy are now required to engage for ten years' "continuous service," from the age of eighteen, and are allowed to count time for pension from that age, instead of from the age of twenty, as heretofore. All men volunteering for ten years' continuous service are also allowed pensions after twenty years' service, instead of twenty-one. In order to insure a certain number of trained seamen, in the event of an armament, in addition to those borne on the peace establishment, seamen who have served ten years continuously in the navy, reckoning from the age of eighteen, are eligible, at the discretion of the Board of Admiralty, to be granted pensions of 6d. a day each, and men with fifteen years' service, pensions of eightpence a day each,—both classes being liable to give further service, if called upon, in the event of an armament. All men and boys, upon entering the service for the first time, and who may be

granted pensions for twenty or twenty-one years' service, **Personnel** are held liable, under the pension stipulation, to give further service, if required, to meet the exigencies of an armament or of war.

To the noble institution of Greenwich Hospital is appended an asylum for the maintenance and education of **Naval Asylum** the children of officers and seamen of the royal naval service.

The Naval Asylum was originally instituted by the Patriotic Fund and private subscriptions, and afterwards established at Greenwich, by warrant under the king's sign-manual, dated in January 1818, appointing the lords commissioners of the Admiralty to be commissioners and governors, who, with twenty-four directors, were to superintend and manage the same. The object was, the maintenance and education of a certain number of orphans and other children of the non-commissioned officers, seamen, and marines of the Royal Navy. As it was manifest, however, that this establishment, so contiguous to the hospital of Greenwich, could be managed without inconvenience by the commissioners and directors of that hospital, under a more effective and economical system, His Majesty was pleased, by his warrant of January 1821, to annul the former warrant, and to vest the superintendence and internal management of the said asylum in the commissioners and governors of Greenwich Hospital.

The two schools of Greenwich Hospital and the **Naval Greenwich Asylum**, and the funds thereof, are now therefore incorporated schools. The internal management is confided to the board of directors, and one of the captains of the hospital is intrusted with the general superintendence. The schools consist of the Nautical School and of the Upper and Lower School. A chaplain, and proper schoolmasters, matron, and inferior assistants, with moderate salaries, reside in the building. The number of children maintained and educated in the institution are,—

In the Boys' Upper School.....	400
... Lower School.....	400
In the whole...800	

The Upper School is divided into two classes. 100 are the sons of commissioned and ward-room warrant-officers of the Royal Navy and Marines; and 300 are the sons of officers of the above or inferior rank, and of private seamen or marines of the navy, and of officers and seamen of the merchant service. The whole 400 are subject to the same regulations as to education, diet, clothing, discipline, and destination. None are admitted unless they can read fluently, write small text, and perform the first three rules of arithmetic. They must be free from infirmity of every description. The age of admission is from ten to eleven; and at fifteen, or sooner if qualified, the whole are sent to sea, either in the navy or merchant service, or are otherwise disposed of. Presentations by the directors in rotation.

The boys of the Lower School are the children of warrant and petty officers and seamen of the naval service, and non-commissioned officers and privates of the Royal Marines, admitted by the board of directors, giving a preference to orphans. The age of admission is from nine to eleven years inclusive; but none are retained beyond the age of fifteen. The boys are sent into the navy or merchant service, if situations can be provided for them; if not, they are to be taken away by their parents or guardians at the age of fifteen.

Thus all the classes of officers, seamen, and marines, who have faithfully served in the navy, are provided for by the state; and the children of such as may be in indigent circumstances receive an education at the public expense, suited to their condition in life.

The total expense of the navy, including every branch of the service, civil and military, for one whole year, about

Navy Bay
Naxos.

the middle of the war with France, was estimated at about L.18,000,000. In the year 1822, according to the estimates which were laid before Parliament, it amounted to about L.5,000,000; and in the year 1837, L.4,663,000; but it would be perhaps better to give a comparison between the year 1835-6 and the year 1856-7, an interval of 21 years. When at peace at the former period, the estimates amounted to L.4,245,723, with a vote for 20,000 men, 2000 boys, and 9000 marines. When at war with Russia during the latter period, the navy estimates amounted to L.16,298,155, with a vote for 71,000 men, being more than three times the number of seamen voted for 1835-6, and very nearly four times the amount.

Some idea may be formed of the prodigious increase of correspondence consequently conducted at Whitehall, by comparing the letters received and registered in the record department of the Admiralty at the same periods. In 1835-6, when Mr (now Sir Charles) Wood was secretary, and Mr Bedford held the office of keeper of the records, 25,973 letters were registered. In 1855-6, when Mr Osborne was secretary, and Mr Barrow (with one additional clerk) was in charge of the department, 49,181 letters were registered: the letters in the previous year having amounted to no less than 53,194, occasioning considerably more than double the amount of work in 1855-6, as compared to the period when Mr Wood was secretary.

NAVY BAY, or LIMON BAY, an inlet of the Caribbean Sea, indenting the N. coast of the isthmus of Panama, in the republic of New Granada; N. Lat. 9. 21., W. Long. 80. It is about 5 miles wide at its mouth, stretches 4 miles into the land, gradually diminishing in depth, and can afford safe and convenient anchorage for many large vessels. On the western side there are several projecting headlands, which afford protection to vessels moored behind them, and which might be rendered still more secure by the construction of breakwaters. On the eastern side of the bay lies the island of Manzanilla, a mile and a half long by a mile in breadth; and between it and the mainland is a channel, with excellent anchorage and good shelter for small vessels under repair. This anchorage is capable of accommodating 300 ships, and has a depth of 6 or 7 fathoms in the centre. On the island of Manzanilla stands the town of Aspinwall, near which there is a railway across the isthmus to Panama.

NAXOS, or NAXIA, an island in the Grecian Archipelago, lying to the E. of Paros, the northern extremity being in N. Lat. 37. 12., E. Long. 25. 33. It is about 18 miles in length, by 12 in breadth, and has an area of 170 square miles. It bore the same name in ancient times; but was also called *Strongyle*, from its round shape; *Dionysias*, in consequence of the worship of Dionysus or Bacchus; and by the poets, *Dia*, in honour of Jupiter. In this island, according to ancient legends, Bacchus found Ariadne, who had been brought from Crete and left here by Theseus. It is said that the earliest inhabitants were Thracians; and that a colony of Carians afterwards settled here under a chieftain named Naxos, who gave his name to the island. It was afterwards colonized by Ionians from Attica; and from its size and fertility rose to great power and prosperity among the Cyclades. The original government of Naxos seems to have been oligarchical, but a tyranny was established by Lygdamis, who, after being expelled, was restored to power by Pisistratus of Athens, whom he had assisted to reinstate in the supreme power over Attica. This state of affairs, however, did not last long; and the aristocratic party again obtained for a time the upper hand; but having been expelled by the people, they applied for assistance to Aristagoras of Miletus, who induced the Persian king

Naxos.

The following table will show the increase in the navy estimates since the introduction of steam:—

Year.	Men voted.	Sum voted.
1810.	Not given L.1,508,451 15 11	
	Supplement 2,624 0 0	
		L.1,511,075 15 11
1820.	Not given L.2,229,904 0 0	
	For conveying and victualling settlers to the Cape of Good Hope 86,760 5 4	
		2,316,664 5 4
1830.	29,000 men	5,595,855 5 8
1840-1.	35,165	5,847,516 0 0
1850-1.	33,446	6,672,588 0 0
1851-2.	33,610	6,543,255 0 0
1852-3.	33,619	5,835,588 0 0
1853-4.	39,407	6,285,493 0 0
1854-5.	50,907 (5000 seamen for 6 months.).....	10,417,309 0 0
1855-6.	65,000	11,857,506 0 0
1856-7.	71,000	16,298,155 0 0
1857-8.	39,000	8,109,168 0 0

At the close of the war with Russia, the navy estimates (1857-8) were cut down from over 16 millions (as above) to L.8,109,168. They now stand (1858-9) at L.9,140,127: and it is to be hoped that they may not be reduced, if the Royal Navy is to remain in that state of efficiency, both in its *personnel* and *matériel*, which must be the ardent desire of every true lover of his country. (J. B.—W.)

to undertake an expedition against the island. This expedition, sent against Naxos in 501 B.C., proved unsuccessful; but in 490 the island was reduced to subjection by the Persians under Datis and Artaphernes. At the battle of Salamis the Naxian contingent of four vessels deserted the Persians, and fought on the side of the Greeks. After the Persian war they joined the league of which Athens was at the head; but in 471 B.C., having revolted, they were reduced by the Athenians to a state of subjection. After this time few important events happened in connection with Naxos, till 1207 A.D., when a Venetian, named Marco Sanudo, took possession of this and some of the other islands, and founded a state, under the name of the Duchy of the *Ægean Sea*. This duchy, after a duration of 360 years, was destroyed by the Turks in 1566, under whom the island continued till the Greek insurrection, after which it formed part of the kingdom of Greece. The island is very fertile and picturesque; and produces vines, olives, oranges, pomegranates, figs, and other fruits. In the centre rises a mountain 3000 feet high, anciently called *Drius*, and now *Zia* or *Dia*; and there is also another eminence called *Coronon*, the name of which is probably derived from the nymph *Coronis*, the nurse of *Bacchus*. The rocks of Naxos consist principally of marble and granite, of which there are quarries; and the marble is hardly inferior to that of Paros. Iron ore is also found. The higher ground affords good pasturage for cattle. The resinous substance called *ladanum* is obtained here in modern as in ancient times. Near the north end of the island is a marble quarry, containing an ancient colossal statue, said to be one of *Apollo*, in an unfinished state. The principal town in the island is that of Naxos, which stands on the site of the ancient capital, on the west coast. It is irregularly built; and though it presents a fine appearance from the sea, the streets are narrow and dirty. It contains the remains of an ancient temple of *Bacchus*, and of the palace of the Venetian dukes, which was plundered by *Barbarossa*; and two moles, one ancient and the other modern, built by *Marco Sanudo*. The population of the town is about 4000. The island is the see of a Greek bishop and of a Roman Catholic archbishop, and has convents of both religions. There are numerous small towns and

Naylor
Nazareth.

villages; and the entire population is estimated at 20,000.

NAYLOR, NATLER, or NAILER, JAMES, an unfortunate fanatic, was the son of a farmer, and was born at Ardsley in Yorkshire about 1616. When the civil war broke out in 1641, he was living with his wife and family in the parish of Wakefield, and was probably engaged in agriculture. He took up arms for the Parliament, and during eight or nine years fought successively under Fairfax and Lambert. It seems to have been about this period that he first began to be seized with sudden religious impulses. He was converted from Presbyterianism to Independency. Then in 1651, two years after he had quitted the army and returned to the plough, the preaching of George Fox drew him into the community of the Quakers. An apostolic zeal immediately fired the new convert, and he abandoned his family and his occupation to become an itinerant preacher. His fevered imagination, untempered by a cool judgment, began to vent itself in the most fanatical opinions. The Quakers, as a body, disowned him; but a few silly men and women accepted his fluent ravings as inspired prophecies; recognised in his constant use of scriptural phraseology a sign of divine sanctity; and at length inferred from his habit of talking about "Christ being in him," that he was the very Son of God. It was no uncommon practice with these devoted disciples to leave their homes in different parts of the country, and to attend their prophet in his wanderings from city to city. Such enthusiastic worship quite overturned the previously tottering judgment of Naylor; so that he appears to have believed himself to be possessed of every supernatural attribute that was ascribed to him. His worshippers, encouraged by his acquiescence, soon brought their fanaticism to a crisis. They knelt before him and kissed his feet as he lay in Exeter jail in 1656, a sufferer for his extravagant zeal. On his release they celebrated his approach to Bristol by singing hosannas and by spreading their garments before his horse's path, in irreverent imitation of our Saviour's entrance into Jerusalem. At this point the government interfered, and apprehended Naylor, with six of his votaries, on the charge of blasphemy. His trial occupied the Parliament for several days. A few days afterwards their sentence was inflicted upon him. His head was fixed in the pillory for two hours, he was whipped at the cart-tail from the Palace-yard to the Old Exchange, his tongue was bored with a red-hot iron, and the stigma of a blasphemer was branded on his forehead. After a short respite, he was conveyed to Bristol, and whipped through the streets of that town. He was then brought back to bridewell, and doomed to an imprisonment of two years. These severe chastisements tamed the delirium and the spiritual pride of the fanatic. He recanted his heinous errors in several small books, and was re-admitted into the communion of the Quakers. In 1660, two years after his release, Naylor set out northward, to visit his long-forsaken family, but died by the way, in Huntingdonshire. A collection of his books, epistles, and papers was printed in 8vo, 1716. *Memoirs of the Life, Ministry, Trial, and Sufferings of James Naylor* appeared in 8vo, London, 1719.

NAZARETH, a town of Galilee in Palestine, stands on the western side of a narrow oblong valley, about 6 miles W.N.W. from Mount Tabor. Before the Christian era it seems to have been a paltry uninteresting village. It is not mentioned even once either in the Old Testament or in Josephus; and it is probable that it was the insignificance of the town itself, rather than the bad repute of its inhabitants, that prompted the exclamation of Nathanael, "Can there any good thing come out of Nazareth?" But the fact that our Saviour passed his youth and early manhood within its humble precincts, invested it with an interest which it has ever since retained, and which it will still retain as long as a single trace of its existence re-

mains. It is now a well-built town, consisting of flat-roofed stone houses, and standing conspicuous amid a neighbourhood fertile with fig-trees, olive-trees, vineyards, and corn-fields. The chief objects of interest in the town are the localities which are pointed out as the scenes of some of the events in our Lord's history, and the richly-decorated church of the monastery erected over a grotto which is supposed to contain the kitchen and fire-place of the Virgin. There is also shown the synagogue in which our Saviour expounded the Scriptures. About 2 miles from Nazareth stands the "Mount of Precipitation," which, as its name implies, is supposed to be the height from which he was about to be thrown by his fellow-townsmen. But how the credulous monks identify this precipice with the hill mentioned in Scripture as that "whereon the city was built," it is difficult to understand. The population of Nazareth is about 3000, of whom the majority are Christians of various denominations, and the rest are Mohammedans.

NAZARITE, or NAZARENE, a term which signifies one who is of Nazareth, or any native of the city of Nazareth. It was given to Jesus Christ and his disciples, and is commonly employed in a sense of derision and contempt by those authors who have written against Christianity. It has also been applied to a sect of heretics called Nazarenes, who sprung up during the second century in Palestine. Their main peculiarity consisted in the imagined necessity of combining the Jewish ceremonial with the religion of Jesus Christ. They refer to a Hebrew Gospel of St Matthew; and the Christian fathers make frequent allusion in their writings to the Gospel of the Nazarenes. This gospel was preserved by them in its primitive purity; but the Ebionites, a contemporary sect which they intimately resembled, and with which they have been often confounded, afterwards corrupted this scripture to suit their own heretical opinions. Both sects seem to have died out before the fifth century. Sometimes Nazarite means one who has laid himself under the obligation of a vow to observe the rules of Nazariteship, whether it be for his whole life, as Samson and John the Baptist, or only for a time, as in the case of those mentioned in Numbers vi. 18, 19, 20; and Amos ii. 11, 12. Lastly, the name Nazarite denotes, according to some, a man of particular distinction and great dignity in the court of some prince. *Nazir* is the Hebrew word employed to designate the dignity of the patriarch Joseph (Gen. xlix. 26; Deut. xxxiii. 16); and Calmet mentions that this word is still applied to the chief minister of the crown in Persia. (See Carpzov, *Appar.*, p. 151, sq., p. 798, sq.; Reland, *Antiq. Sacr.* ii. 10; Meinhard, *De Nasirais*, Jen., 1676; Zorn, in *Miscell. Lips. Nov.* iv., 426, sq.; Spencer, *De Leg. Heb. Rit.* iii. 6; Dongtzei, *Analect.* i. 37; Lucian, *De Dea. Syr.*, c. 60; Mishna, *Nasir.*)

NEAGH, LOUGH, a lake of Ireland, province of Ulster, bounded N. and E. by Antrim county, W. by Tyrone, and S. by Armagh. It is the most extensive lake in the United Kingdom, and one of the largest in Europe, measuring 18 miles in length by 11 in breadth, and covering an area of 98,255 acres. The height of its surface above the level of the sea at low water is 48 feet, and its greatest depth is 102 feet. The lake is far from picturesque, and contrasts unfavourably with the other loughs of Ireland. Its shores are low and flat, and frequently become flooded after heavy rains. There are several islets, one of which, Ram's Island, is 6 acres in extent, and contains the remains of a round tower. The principal streams which flow into the lake are the Blackwater, the Upper Bann, and the Six-Mile Water; and its only outlet is the Lower Bann, which leaves the lough at its N.W. corner, and after flowing through Lough Beg, enters the sea near Coleraine. It is connected by canals with Belfast, Newry, and Lough Erne. It is navigated by small vessels; and one or two commodious ports or harbours are stationed along its coasts. The waters of the lough have

Nazareth.
Neagh.

Neal
||
Neander.

strong petrifying qualities, and the petrification is silicious and susceptible of a beautiful polish. The fish most abundant are the pollan (*Coregonus pollan*), a bright silvery fish, resembling the herring; and the *dollaghan*, a species of trout. Numbers of aquatic birds, such as the heron, widgeon, &c., frequent the shores.

NEAL, DANIEL, the author of an able *History of the Puritans*, was born in London in December 1678. After receiving his elementary education first at Merchant Tailors' School, and subsequently at a dissenting academy, he spent three years on the Continent, studying successively at Utrecht and Leyden. On his return in 1703 he commenced to preach. His learning and abilities recommended him in the following year to the office of assistant to Dr Singleton, the minister of an Independent congregation in Aldersgate Street. The Doctor died in 1706, and Neal was chosen his successor. He now appeared as a most faithful pastor, and at the same time as an assiduous cultivator of polite letters, especially of history. The *History of New England*, published in 1720, introduced him to the literary public. Meanwhile several of his sermons, preached for charitable purposes or on special occasions, were printed by request, and gained for him considerable fame as a pulpit orator. About 1729 he had risen so high in the estimation of his co-religionists, that he was requested to undertake an historical account of the Nonconformists. Accordingly, the first volume of *The History of the Puritans*, commencing at the Reformation in England, was published in 1732; the second followed in 1733, and the third in 1736. The fourth, bringing the narrative down to the Act of Toleration of 1689, was published in 1738. This history, though written in a calm and judicious spirit, was accused of being one-sided, and was attacked by Bishop Maddox and Dr Zachary Grey. Neal answered the former, and would in all probability have answered the latter also, had not his declining health prevented him. He died in April 1743. Neal's *History of the Puritans*, accompanied with a Life of the author, was edited by Toulmin in 6 vols., 1793. The same edition was reprinted in 3 vols. 8vo, London, 1837.

NEALCES, an ancient Greek painter, flourished in the time of Aratus of Sicyon, about the middle of the third century B.C. Little is known regarding either his life or his works. A Venus, and a painting of the naval battle on the Nile between the Egyptians and Persians, are mentioned by Pliny as two of his masterpieces. In the latter of these he very happily indicated the country in which the scene was laid, by representing a crocodile on the eve of seizing an ass that was drinking at the river. Nealces had a daughter named Anaxandra, who became an artist. The painter Erigonus was once his colour-grinder.

NEANDER, one of the most distinguished and influential of the modern theologians of Germany, was born at Göttingen in the beginning of 1789 of Jewish parents. His father Emmanuel Mendel, is said to have been a common Jewish pedlar; but little seems to be really known of his circumstances and character. His mother was a woman of tender and noble disposition; and from the maternal side, as in so many other cases, the virtues and talents of the son appear to have sprung. While still young, he removed with his mother to Hamburg; and in the grammar school, or Johanneum, of that city he received his classical education. There, as throughout life, the simplicity of his personal appearance, and the oddity of his manners, attracted notice, but still more, under all outward peculiarities, his great industry and mental power. His teacher, Gurlitt, took pride in his progress; and to the countenance and encouragement he thus received he owed much, which he always remembered with gratitude. From the Johanneum young Mendel passed to the gymnasium, where he attended for a year the prelections in philology, philosophy, and theology. The

Neander.

study of Plato appears especially to have engrossed him at this time. One of his young friends, Wilhelm Neumann, writes of him in 1806,—“Plato is his idol—his constant watchword. He sits day and night over him; and there are few who have so thoroughly, and in such purity, imbibed his wisdom. It is wonderful how entirely he has done this without any foreign impulse, merely through his own reflection and downright study.”

Considerable interest attaches to his early companionship with the writer of this letter, and certain others, among whom were the afterwards well-known writer Varnhagen Von Ense and the poet Chamisso. This young band of students, strongly devoted to the romantic school of Tieck and Schlegel, had started a poetical periodical, in connection with which they formed themselves into a literary union, under the symbol of the Pole Star. The Star of the North, the region of enlightenment, was meant to signify their aspiring cultivation of the true and the beautiful. Varnhagen and Neumann having come to Hamburg, were attracted by the kindred spirit of the young Jewish student, and enrolled him in the brotherhood. He adopted the common symbol, and in virtue of his new connection opened up a correspondence with Chamisso, which was fortunately preserved by the latter, and gives us the deepest insight which we possess into his views and character at this period. The letters are singularly interesting. They breathe throughout the most simple and glowing enthusiasm; while the picture of a pure and affectionate nature, and the struggling comprehensiveness of a great spirit, are impressed on every page of them.

These letters enable us to understand with some degree of clearness the great change which now took place in Neander's convictions. They reveal a course of spiritual training very much analogous to that which he has described in many cases, with such remarkable power, in his *Church History*. He reached the gospel through Platonism. In that philosophy which, he continued to think, addresses itself more directly than any other to the divine instincts in man, and which, he has expressly said, “contains so much that really or seemingly harmonizes with Christian truth,” he found those points of contact with Christianity which always attracted him more closely to it as a source of spiritual life, and the satisfaction of all his inward necessities. The ideals which in Plato “ravished his intellectual vision,” and were at first worshipped with that intense devotion which leaves no room for any other worship in the heart of the student, he found in the gospel transmuted into realities, fitted not only to dazzle his intellect, but to pacify his heart and quicken and ennoble his whole being. Plato was thus his schoolmaster to bring him to Christ. And while he never ceased his admiration of the philosopher, he yet always came to embrace more and more, in its depth and purity, the “truth as it is in Jesus.” The influence of his teacher's idealism may be visibly traced in some of his conceptions of Christian doctrine; but the divine simplicity and practical power of the gospel asserted themselves always more strongly in him. He was baptized on the 25th February 1806, and on this occasion adopted, instead of his Jewish name of David Mendel, that, under which he was always afterwards known, of Augustus Neander (νεὸς ἀννης).

In the same year he went to Halle to study divinity. He had matriculated at the gymnasium in Hamburg as *juris studiosus*; but with his new views, and the earnest spirit which animated him, he could now only serve the church. At Halle, Schleiermacher was then lecturing in the first height of his fame as a teacher. Neander met in him the very impulse which he needed, while Schleiermacher found a pupil of thoroughly congenial feeling, and one destined to carry out his views in a higher and more effective Christian form than he himself was capable of imparting to them. From this period we are to date Neander's devotion to

Neander. church history. Catching the enthusiasm and higher appreciation of his teacher, he began to live in studious communion with the fathers, and to amass those stores of divine wisdom and lore which he drew so copiously from their writings. His repose at Halle, however, was soon disturbed. The French having taken possession of the town after the battle of Jena, the university was suspended, and the professors and students scattered abroad. Neander had the misfortune, along with some other students, to be robbed by the French soldiers; and, friendless and ill from the fatigue of the journey on foot, he at length found refuge in his native city. Here he continued his studies with ardour, made himself yet more master of Plato and Plutarch, and especially advanced in sacred learning under the venerable Planck. The impulse communicated by Schleiermacher was confirmed by Planck, and he seems now to have realized that the original investigation of Christian history was to form the great work of his life.

Having finished his university course, he returned to Hamburg, and passed his examination for the Christian ministry with great distinction. He was not fitted, however, for the pulpit, and never seems to have commenced preaching. He betook himself to an academic career, and the study of Christian history, in Heidelberg, where two vacancies had occurred in the theological faculty of the university, from the removal of Mahreineke and De Wette to Berlin. He entered upon his work here as a theological teacher in 1811, commencing with a Latin dissertation on a subject which never ceased to attract him (*De fidei gnoseosque idea secundum Clementum Alex.*); and in the year following an extraordinary professorship rewarded his learning and industry. In the same year (1812) he first appeared as an author by the publication of his monograph on the Emperor Julian. The fresh insight into the history of the church, and the vivid and striking power of delineation evinced by this work,—vague and sketchy, perhaps, as it now seems in the light of his maturer productions,—at once drew attention to its author, and marked him as a rising theologian of the first rank. Accordingly, even before he had terminated the first year of his academical labours at Heidelberg, he was called to Berlin as the associate of De Wette and Schleiermacher—an illustrious band, whose labours have left an ineffaceable impress upon German theology.

In Berlin, Neander settled at once to those laborious habits of study and of earnest faithfulness in the discharge of his professorial duty which distinguished all his future career. His life was only varied by the successive publications which appeared in such fertility from his pen. In the year following his appointment he published a second monograph on St Bernard and his Age; then in 1818 his work on Gnosticism. A still more extended and elaborate monograph than either of the preceding followed on Chrysostom; and again, in 1825, another on Tertullian. He had in the meantime, however, begun his great work, to which these several efforts were only preparatory studies. The first part of his *General History of the Christian Religion and Church* made its appearance in 1825, embracing the history of the first three centuries. The remaining parts have appeared at successive intervals,—the last volume since his death, bringing down the narrative to the eve of the Reformation. Besides this great work, he published in 1832 his *History of the Planting and Training of the Christian Church by the Apostles*; and in 1837 his *Life of Jesus Christ, in its Historical Connection and Development*, called forth by the famous *Life* of Strauss. In addition to all these labours, he gave to the public many miscellaneous sketches from the history of the church and of theological opinion; as, for example, his *Memorabilia from the History of the Christian Life*, his volume under the title of the *Unity and Variety of the Christian Life*, and his papers

on Plotinus, Thomas Aquinas, Theobald Thamer, Pascal, Newman, Blanco White, and Arnold, &c. Several brief works of a mixed exegetical and historical character have also come from his pen; and since his death a succession of volumes, representing his various courses of lectures, have been promised, of which two, containing his *Lectures on Dogmengeschichte*, admirable in spirit and execution, appeared last year (1857).

The life of Neander, as may be gathered from this mere enumeration, was one of unwearied work in his study and in his lecture-room. He lectured usually three times a day, his lectures embracing almost every branch of theology, exegetics, dogmatics, and ethics, as well as church history. He cherished the most warm and affectionate interest in his students, his ungrudging self-denial and benefactions in their behalf forming one of the most kindly traditions which surround his name. It is difficult to conceive a more child-like and yet more aspiring nature; at once so simple and so subtle—so lovely in affectionateness, and yet so grand and comprehensive in capacity and views. He died in 1850, worn out, and nearly blind, with incessant study. Germany mourned him as one of the greatest of her sons.

Our space will not permit us to enter into any full appreciation of Neander's theological and historical labours. This could only be done by showing at length his relation to the previous theology of Germany, and especially his connection with Schleiermacher, and the manner in which, while adopting, he modified and carried out the principles of this great thinker. With a mind less restlessly speculative, less versatile, discriminating, and logical, he possessed, in higher union than Schleiermacher, depth of spiritual insight and purity of moral perception with profound philosophical capacity. Characteristically meditative, while Schleiermacher was characteristically dialectical, he rested with a more secure footing on the great central truths of Christianity, and recognised more thoroughly their essential reasonableness and harmony. Strongly alive to the claims of criticism, he no less strongly asserted the rights of Christian feeling. "Without it," he emphatically says, "there can be no theology; it can only thrive in the calmness of a soul consecrated to God." And exactly in the same spirit, and proceeding from the same strong recognition of the absolute necessity of this Christian element in all theology, was his favourite motto,—"*Pectus est quod theologum facit.*"

His *Church History* remains the greatest monument of his genius; and, upon the whole, the greatest work that has yet attempted to embrace so wide a field. Defective in graphic personal details and in a clear exhibition of the political relations of the church, somewhat heavy in style, with a certain vagueness and want of pictorial life throughout, it is yet unrivalled in its union of vast learning and profound philosophic penetration; its varied comprehensiveness and abundant store of materials; its insight into the living connection of historical events, but especially into the still more living and subtle nexus which binds together the growth and development of human opinion;—in its display of such qualities, with the most simple-hearted Christian piety, the most lively appreciative interest in the ever-varying fortunes of the church, the finest discernment of all the manifold phases of the Christian life, the most genuine liberality, and the most catholic sympathy. (J. T.—H.)

NEAPOLIS. (See NAPLES.)

NEARCHUS, a distinguished ancient admiral, was the son of Adrotimus, and was born in Crete in the former half of the fourth century B.C. Obtaining a high position at the court of Macedon, he became a devoted friend of the young Alexander, and was banished on that account by the suspicious Philip. Alexander, on succeeding to the throne, recalled him; and Nearchus in 335 B.C. set out with the

Neapolis
||
Nearchus.

Neath.

king on his career of conquest. He was left behind in the following year to govern Lycia and Pamphylia. Five years afterwards, however, he joined the conquering prince once more in the far-distant province of Bactriana. But it was not until 325 B.C. that a high command was conferred upon him. A fleet was then launched upon the Hydaspes, and Nearchus was appointed to conduct it to the sea. This was effected in safety; but the more difficult task of leading the ships through the unexplored Indian waters to the Persian Gulf remained to be accomplished. Nearchus volunteered his services, which were gladly accepted. He set sail from the mouths of the Indus about the end of September 325 B.C. On approaching nearly opposite the western border of the Indians, the ships were obliged to tarry for twenty-four days in a port, afterwards called Alexander, until the north-east monsoon had set in. From this point the inexperienced mariners began to be encompassed with perils and objects of terror. A storm met them, and destroyed three of the galleys; they were under a perpetual dread of running upon rocks and shoals; huge sea-monsters rose upon the surface of the water, and threatened to overwhelm them; when they drew close to the land, ferocious savages, covered entirely with shaggy hair, and armed with nails like those of wild beasts, glared upon them from the shore. When at length, they arrived opposite the country of the Ichthyophagi, Leonnatus, who at the head of a land army had hitherto supplied them with provisions, could no longer attend them; and the barren sandy plain that extended for hundreds of miles along the shore could afford them no sustenance. The crews, appalled at the inevitable famine and the weary stretch of unknown sea that lay before them, became faint-hearted and refractory. At this crisis the indomitable energy of the admiral saved all from destruction. Overbearing the spirit of disobedience by his commanding firmness, he steered right onwards for many days, in spite of hunger, and danger, and discontent, until he landed his famished sailors on the fertile shores of Carmania. The remainder of the voyage was comparatively easy; and on the 9th December he brought his ships to anchor at the mouth of the River Anamis near the town of Harmozia. He then hastened to the camp of Alexander, which was pitched at a short distance in the interior, to announce his arrival. "By the Grecian Zeus and the Lybian Ammon!" exclaimed the king, "I swear to you I am more happy in receiving this intelligence than at being the conqueror of all Asia." From this date the facts known concerning Nearchus are comparatively unimportant. In the beginning of the following year (324 B.C.) he conducted his fleet to Susa. When the empire of Alexander was divided, his old provinces of Lycia and Pamphylia fell to his lot. He became an attached friend of King Antigonus. The latest mention of him in history is in 314 B.C., when he was appointed one of the counsellors of Demetrius, the son of the above-named monarch.

A narrative of the famous voyage of Nearchus is said to have been written by the navigator himself, and to have furnished the materials of Arrian's *Indica*. This opinion has been contested by Dodwell and other critics; but has been upheld by the generality of authorities, and especially by Dr Vincent in his *Commerce and Navigation of the Ancients in the Indian Seas*. The work just mentioned also gives a full account of the voyage.

NEATH, or NEDD (anc. *Nidum*), a parliamentary and municipal borough and market-town of South Wales, in the county of Glamorgan, on the left bank of the river of the same name, 7 miles E.N.E. of Swansea, 35 W.N.W. of Cardiff, and 208 W. by N. of London by railway. It extends along the edge of the river; and though neither well nor regularly built, it has some broad, well-paved streets. In the middle of the market-place stands a town-

hall, built in 1837. The parish church is a large and ancient structure, with a square embattled tower; and there are several other churches. The town has a philosophical society, mechanics' institution, library, museum, and several almshouses. There are extensive copper and iron works, and the trade is considerable. The River Neath, which is here crossed by a bridge, is navigable for vessels of 300 or 400 tons up to the town, where there is a harbour with convenient docks. The principal articles exported are coal, iron, copper, tin, oak, and bricks; while copper and iron ore, corn, flour, timber, and other goods, are imported from foreign countries. Near the town are the remains of an old castle; and about a mile off, on the road to Swansea, are those of Neath Abbey; but very few traces now remain of the former splendour of either of these edifices. The borough is governed by a mayor, 4 aldermen, and 12 councillors; and unites with Swansea in returning a member to Parliament. The market-day is Wednesday; and three annual fairs are held. Pop. (1851) 5841.

NEBRASKA, a territory of the United States of North America, bounded N. by British America; W. by the Rocky Mountains, which separate it from Washington, Oregon, and Utah; S. by Kansas; and E. by Iowa and Minnesota. It lies between N. Lat. 40. and 49., and W. Long. 95. and 118.; and has an estimated area of 335,882 square miles. The country is still in its wild, primitive condition, and little is known of its topography, except in the neighbourhood of the Missouri and Platte rivers. The greater portion is an immense plain, sloping gradually from the Rocky Mountains in the W. to the Missouri in the E. Little of it is mountainous, except that part contiguous to the Rocky range. The principal rivers are the Missouri and its affluents the Platte, or Nebraska, and the Yellowstone. The country on both sides of the former tributary, as far up as the Elkhorn, is described as an undulating plain, here and there broken by ravines of considerable abruptness. But farther up the quality of the land deteriorates, and, except in the immediate vicinity of the river, is unfit for cultivation. The section of the territory at the head of Platte River, called the Black Hill district, is more elevated and is well watered. Many of the hills are covered with pine and cedar, and the valleys are said to be luxuriantly clothed with grass. From Fort Laramie, on the same river, there extends, for a distance of about 90 miles, a remarkable tract of land called "the Bad Lands," on account of its great sterility and forbidding aspect. It is studded with a number of columnar masses of sandstone from 100 to 200 feet high, which give it all the appearance of a vast, though quaint old town entirely deserted by its inhabitants. An interest of another kind has also been imparted to this place by a number of fossil skeletons of various tribes of animals now extinct, particularly of the *Pachydermata*, being found here, among which the skeleton of a *Palæotherium* was discovered 18 feet in length. The Platte valley forms one of the highways for overland emigrants to Utah and California. The river is from one to three miles broad, but yet so shallow, that, excepting at high flood, it is fordable at almost any part. The course of the stream is obstructed by numerous islands covered with cotton-wood, willows, and shrubs; while the shifting sand-banks and the rapidity of the current effectually prevent navigation. It rises among the Great River Mountains, and, under the name of the North Fork, flows E. by S., till joined by the South Fork, when it assumes the name of Platte or Nebraska River. It discharges its water into the Missouri near Plattville, after a course of about 1200 miles. The Yellowstone River, which waters the northern part of Nebraska, though not so long as the Platte, has a greater volume of water. It rises in Sublette's Lake, N. Lat. 43. 40., and W. Long. 110., and after a north-easterly course of about 1000 miles, joins the Missouri at Fort Union.

From the condition of the soil and surface of Nebraska,

Nebraska.

Nebuchadnezzar. it will in all likelihood become an agricultural country of some importance. The climate is warmer than in the same latitude east of the great lakes. Owing, however, to the vast extent of prairie land, the temperature is subject to sudden changes, and the country is exposed to the north and west winds, which sweep over the plains with great violence. It is reported that minerals exist to a considerable extent, and coal is said to have been lately discovered here. Emigrants have not as yet flowed into the territory in large numbers; and hence it is that here the Indians are found in greater numbers, and in a less civilized state, than in any other part of the Union. The government have assented to the construction of several roads through Nebraska, which, when completed, will no doubt tend greatly to the increase of its population. The territory formed a part of the Louisiana purchase, and came into the possession of the Union in 1803. It then comprehended the territory of Kansas, which was separated from it and organized a territory of the Union in 1854. Nebraska, as it now stands, received a like privilege in the same year. The capital town is Omaha city, situated on the west side of the Missouri. The entire white population was estimated in 1854 at 6000.

NEBUCHADNEZZAR, NEBUCHADREZZAR, or NABOPOLASSAR, a great Chaldean king of Babylon. The account of his life given in the sacred narrative has received considerable elucidation from the canon of Ptolemy the mathematician, and from an extract preserved by Josephus out of a history by Berosus, a priest of the temple of Bel. From the combined import of these three narratives, we gather that Nebuchadnezzar, having virtually received the sovereign power from his infirm father Nabopolassar, set out at the head of a mighty army to chastise Necho, King of Egypt. The Egyptian monarch, after subduing the kingdom of Judæa, had advanced as far as the banks of the Euphrates, and had seized upon Carchemish (*Circesium*). There the youthful Chaldean prince met him, routed his army, and retook the captured city. The Jews, deprived of the support of their allies, yielded to the conqueror; their king Jchoiakim became a tributary of Babylon; and within two years the Egyptian influence in Syria was completely crushed. At this time (605 B.C.) Nebuchadnezzar received intelligence of his father's death. Leaving his army to conduct the captives and the spoils to Babylonia, he hastened home with a slender escort to assume the sole sovereignty. To consolidate his throne by an alliance, the young king married Amytis, the daughter of the King of Media. About the same time his great and splendid genius, unoccupied by schemes of conquest, began to find a congenial exercise in expensive improvements and gorgeous architecture. He decorated the temple of Belus to a superb magnificence with the treasures and the sacred vessels from Jerusalem; he planned stupendous canals, rivalling in depth and breadth the river Euphrates; and he laid the foundations of that massive and lofty palace, whose terrace-gardens, hanging from its sides like woods from the brow of a mountain cliff, became the wonder of the world. These peaceful occupations were interrupted by the intelligence that the Jews, instigated by Necho, King of Egypt, had rebelled. In the eighth year of his reign Nebuchadnezzar was besieging Jerusalem in person. The city was soon forced to surrender; the newly-appointed king Jehoiachim was deposed; the temple and the palace were plundered; no less than 50,000 captives, including Ezekiel the prophet, the nobles of Judah, and the craftsmen, followed in the train of the conqueror to Babylon; and Zedekiah, the brother of the late monarch, was left to govern the remnant. But no sooner had the Chaldean monarch departed to his distant capital, than his old enemies the Egyptians began to plot against him. They had induced Zedekiah to renounce his allegiance to Babylon, and had sent an army under their

king Hophra to support him in his rebellion, when Nebuchadnezzar, at the head of all the forces of his empire, reappeared in Palestine. After driving the Egyptians back into their own country, he sat down before Jerusalem in 590 B.C. A hot siege of two years ended in the complete surrender of the city to his merciless vengeance. As a summary punishment upon the refractory Jews, he condemned their capital city to be first plundered of all its brass and gold, and then reduced to ashes, and their entire nation to be carried into captivity. The plunder of this expedition, like that of former expeditions, was devoted to the adorning of the royal seat of the conqueror with specimens of art and enterprise. One of these was the gigantic golden image which is mentioned by the prophet Daniel. Nebuchadnezzar was yet destined to be the minister of Divine vengeance upon the idolatrous Tyrians and Egyptians. At the end of an arduous siege of thirteen years, he took the city of Tyre, and levelled it with the dust. The Egyptians, who had added to their former provocations by sending succours to the besieged Tyrians, then became the object of his attack. Invading Egypt he marched from Migdol to Syene, overwhelming all resistance, taking numerous captives, and filling the entire length and breadth of the land with burning cities and slaughtered citizens. This campaign seems to have closed the military career of the Babylonian conqueror. He returned home to enjoy in peace the sway of that wide empire which had been won by his sword, and the splendour of that metropolis which had become under him the queen of the cities of the earth. His pride, pampered by the remembrance of an uninterrupted series of successes, swelled to a monstrous height. Walking one day in his palace, and looking down upon the imposing scene of magnificent houses around him, he burst out into an apostrophe of self-exultation. Immediately a voice fell from heaven, dooming him to live like a beast of the field until he should learn "that the Most High ruleth in the kingdom of men, and giveth it to whomsoever he will." In the same hour the arrogant, self-elated monarch was changed into a bewildered monomaniac that fancied himself an ox, and fled from the abodes of men to eat grass in the wilderness. At the close of seven years, he was restored to his reason and to his kingdom; and it is probable that the rest of his days were passed in that humility of spirit which becomes a creature. He died in 562 B.C. and was succeeded by his son Houaroudamos, or Evil-Merodach.

NECKAR, a river of Germany, rises in Würtemberg, near the borders of Baden, in the Black Forest, not far from the source of the Danube. It flows in an irregular course, first N.E., traversing the N.W. corner of Hohenzollern, then N. through Würtemberg, and finally nearly W. through Baden, to the Rhine, which it joins at Mannheim. Its principal affluents are the Enz, on the left side, and the Kocher and Jagst, on the right. The towns of Rothenberg, Tübingen, Esslingen, Heilbronn, and Heidelberg stand on its banks; and those of Stuttgart and Louisburg are in its vicinity. The whole length of the river is about 270 miles, and it is navigable as far up as Cannstadt, 120 miles from its union with the Rhine.

NECKER, JACQUES, a statesman and financier of France, was born at Geneva on the 30th of September 1732. He was descended from a respectable family, originally from North Germany, and his father was a professor of law in Geneva. At the age of fifteen he quitted Geneva, and proceeding to Paris, entered first into the banking-house of Vernet, and afterwards into that of Thelluson, of which he became the cashier, and at length a partner. On the death of Thelluson, he established a bank on his own account, by which he accumulated a very large fortune. After twenty years of unremitting attention to his profession, he married a Protestant lady of respectable family, and having retired from business, was shortly afterwards named minister of the

Neckar
||
Necker.

Necker. republic of Geneva at Paris. In accepting of this employment, he refused the emoluments which were attached to it; a degree of forbearance not very usual in public men, but in which he resolutely persisted during the whole course of his political life. In 1769 he published the *Compagnie des Indes*; and the *Essai sur la Législation et le Commerce des Grains*, as well as the *Eloge de Colbert*, which was crowned by the French Academy, greatly extended the reputation of his political talents.

The disorder in the state of the French finances had become so alarming, that it was found necessary to break through the routine of official promotion, and to choose able men for the public service wherever they could be found. M. Necker, although a foreigner and a Protestant, was accordingly appointed in the year 1776 director of the royal treasury, and in the following year director-general of the finances. The great object of M. Necker was to introduce order and economy in the public management. With this view, he found himself compelled either to suppress useless offices, or to diminish emoluments; and his retrenchments drew upon him the enmity of all those who suffered by his economical reforms. He published in 1781 the well-known piece on the state of the finances entitled *Le Compte Rendu au Roi*, which had not the effect of lessening the number or violent hostility of his enemies. In order the better to struggle with his opponents, he made a demand for a seat in the Council, but was objected to on the ground of his religion. Being persuaded that this scruple would be abandoned, he persisted, and offered his resignation, which was accepted; and in this manner, as is alleged, he became the dupe of his own presumption.

He now retired to Switzerland, where he purchased the barony of Coppet. In 1784 he published an able work entitled *De l'Administration des Finances*, in 3 vols. 8vo, of which 80,000 copies were speedily sold. In 1787 M. Necker sent a memorial to the king, for the purpose of proving the correctness of his calculations in the *Compte Rendu*. His Majesty having read these documents, requested that they might not be published, a proposition in which Necker did not acquiesce, and for this offence he was exiled, by a *lettre de cachet*, 40 leagues from Paris.

Calonne, however, and the Archbishop of Toulouse were found unequal to the task of regulating the French finances, and were successively obliged to resign and make way for Necker, the favourite of the people, who was reinstated in his former post in August 1788.

At this period the French government was assailed by a complication of difficulties, the chief of which was the impracticability of raising the necessary supplies, and the danger of an immediate bankruptcy. A great scarcity also prevailed at Paris, which rendered the populace unusually discontented and tumultuous. Louis XVI. and his advisers pursued a weak and vacillating policy; and, when it was too late, desperately meditated even the most violent measures for the recovery of their authority. Troops were drawn from the most distant parts and encamped around Paris, intended to overawe the deliberations of the Assembly, or perhaps to dissolve it at once at the point of the bayonet. These violent courses M. Necker opposed, and he accordingly, at his own suggestion, was dismissed on the 11th July 1789, and requested to quit the kingdom in twenty-four hours. It is impossible to describe the consternation and wild confusion which prevailed in the capital when the dismissal and exile of this favourite minister was made known. His recall was demanded by the enraged populace, and a letter was written to Necker at Basle, requesting him to return. This popularity, however, was not of long duration. Being alarmed by the excesses which had already taken place, Necker became desirous to support the authority of the sovereign; and, without conciliating the confidence of the king's friends,

he lost that of the popular party. His personal safety being now in danger from the violence of the people, he quitted Paris in the most private manner in the month of December 1790.

After the loss of his power and popularity, Necker seems to have sunk into the greatest dejection. "I could have wished," says Gibbon, who passed some days with him about this period, "to have exhibited him as a warning to any aspiring youth possessed with the demon of ambition. With all the means of private happiness in his power, he is the most miserable of human beings; the past, the present, and the future, are equally odious to him. When I suggested some domestic amusements, he answered with a deep tone of despair, 'In the state in which I am, I can feel nothing but the blast which has overthrown me.'" He had recourse to writing to divert his melancholy; and several works which he published were the fruits of his labours during this period. He died at Coppet on the 9th of April 1804, after a short but painful illness.

His writings, besides those already mentioned, are,—*Memoire sur les Administrations Provinciales*, 1781; *De l'Importance des Opinions Religieuses*, 1788; *Sur l'Administration de Necker, par lui-même*, 1791; *Du Pouvoir Exécutif dans les Grands Etats*, 1792; *De la Revolution Française*, 1797. (See his *Memoires* by his illustrious daughter, Madame de Staël. A complete edition of Necker's *Œuvres* was published in 15 vols. 8vo, Paris, 1821.)

NECTAR, among the early Greek and Roman poets, was the drink of the gods (*ambrosia* being their food), and was fabled to have the power of imparting health, vigour, youth, and beauty to all who drank of it.

NEDJED, a district of Arabia. (See **ARABIA**.)

NEEDHAM, JOHN TUBERVILLE, was born at London on the 10th September 1713, and was descended from an ancient and noble family. He studied and taught rhetoric at the English college at Douay, conducted a Roman Catholic school near Winchester, and in 1744 was appointed professor of philosophy in the English college at Lisbon. Ill health soon compelled him to leave Portugal, and he passed several years at London and Paris, which were principally employed in microscopical observations, and in other branches of experimental philosophy. The results were published in the *Philosophical Transactions* of the Royal Society of London, of which he was a member, in 1749, and at Paris in 1750, in 1 vol. 12mo. An account of them was also given by his friend Buffon in the first volumes of his *Natural History*. From 1751 to 1767 he was chiefly employed as a travelling tutor, and in 1768 he retired to the English seminary at Paris. He afterwards received the appointment of chief director of the Imperial Academy, then instituted in the Austrian Netherlands, where he remained till his death, on 30th December 1781.

The papers of Needham inserted in the *Philosophical Transactions* are contained in vols. xlii., xlv., and li. He also wrote a curious pamphlet in connection with the controversy then in agitation respecting the origin of the Chinese, entitled *De Inscriptione quadam Ægyptiaca Taurini inventa, et characteribus, Ægyptiis olim et Sinis communibus exarata*, 1761, in 8vo.

NEEDLES. These useful articles are made of steel wire, which may be *mill-drawn* or *hand-drawn*. The latter is preferred for the best needles, because, as in that case there is only one wire running at a time, the drawer can feel when the surface *rips* or *tears*, and can stop the process, so as to re-adjust the draw-plate and remove the damaged wire. In cleaning the wire after it has been softened, the scale is not removed by pickling in dilute sulphuric acid, but by the friction of rubbers smeared with emery and oil. The needle-maker obtains his wire in

Needles.

coils of various sizes and weights, and his first operation is to cut it into lengths, each of which is sufficient for two needles. The curved pieces thus cut from the coils are straightened by inclosing many thousand lengths within a couple of rings, and rubbing them with an iron instrument called a *smooth file*; the friction of the pieces of wire upon each other producing the intended effect. Before this operation the wires are sometimes softened by being raised to a red heat, and allowed to cool gradually. The next process is to point both ends of the wires, which is done on small grit-stones; the grinder holding a number of wires in his left hand, and by a peculiar motion of the right hand making them roll upon the stone, so as to produce an accurate point. This dry grinding loads the air with particles of grit and of steel, which, entering the lungs, produce a fatal disease, known as *grinder's asthma*. The remedy for this is to attach to each wheel a ventilating apparatus capable of carrying off the dust as fast as it is formed. After the wires have been pointed, the centre of each is stamped or flattened out, and a groove is sunk on each side, together with a small cavity for the eye, by means of dies. One of the dies is contained in a block of iron resting on wood, and the other is attached to the bottom of a hammer, so connected with a lever as to be worked by the foot of the stamper; by which means the centre of each wire is flattened out, and the shape of the two eyes given. If it were attempted to form the eyes at one punching, the wire would probably be torn. In the next operation, called *eyeing*, a couple of steel points or cutters are brought down to punch out the eye. The wires are now threaded by their eyes upon a couple of wires, and the bur formed by stamping out the blank eyes is filed off. The lengths are next divided, by bending the wires backwards and forwards between the two wire spits; and shape is given to the heads of each row of needles by grasping the points in a hand-vice, and filing the heads upon a raised piece of metal. The needles are now said to be *headed* or *made*, and this completes the processes known as *soft work*, from the soft state of the wire. Before the finishing processes known as *bright work* are entered on, the needles are straightened by rolling them on a flat steel plate with the convex face of a curved smooth steel file. The next process is *hardening*: the needles being raised to a red heat are suddenly quenched in cold water or oil, after which they are tempered by a more gentle heating on an iron plate, the proper temper being judged of by the formation of a blue film upon the surface. In this operation the needles become more or less distorted, and they are straightened by being tapped upon an anvil with a small hammer: this is called *hard* or *hammer straightening*. The needles are examined by rolling with the finger on a smooth plate of steel, and such as do not roll truly are corrected with the hammer. The needles are now made up with canvas, in bundles of from 40,000 to 50,000, with emery, oil, and soft soap, each bundle being about 2 feet in length, and 3 or 4 inches in diameter. These rolls are placed in a scouring machine, resembling an ordinary mangle, and the bundles being made to roll backwards and forwards during many hours, such an amount of friction is produced on the needles as to make them bright and smooth. After about eight hours' friction the bundles are taken out and re-made, with the addition of putty-powder and oil. For the best needles the scouring or cleaning and polishing is continued for seven or eight days. The heads of the needles are now softened by placing them in rows upon metal strips, with the eyes projecting over the edge, and bringing a red-hot plate sufficiently near to produce the deposit of a dark blue film on the heads. This indicates the proper temper for the next operation, which is the very delicate one of removing sharp or jagged portions from the interior of the eye. This is done by *drilling*, the drills being minute three-sided

tools attached to a wheel, and revolving rapidly. The operator brings each eye up to the drill, first on one side and then on the other; first *countersinking*, as it is called, or converting the sharp edge of the eye, where it communicates with the groove, into a curved one; after which the drill is made to pass round the rest of the eye in such a way as to produce the kind of curve seen in the bow of a pair of scissors. The points are next finished upon a small revolving stone, after which they are polished on wheels of wood coated with buff leather and polishing paste. The needles are lastly counted into quarters of hundreds, folded up in papers, and labelled. Recently they have been sold in cases, containing several small tubes, each tube holding a different size of needle.

The needle-making district of England includes the villages of Redditch, Feckenham, Beoley, Studley, Coughton, Alcester, Astwood Bank, Crabb's Cross, &c.; all of which lie near together. It should be noticed that the manufacture differs somewhat for the heavier kinds of needles, such as packing, sail, upholsterers', stay, mattress, book-binding, surgeons', harness, and collar needles; knitting, netting, tambour, and crochet needles; and meshes. (C.T.)

NEEDLES, THE, a name given to five remarkable rocks lying immediately off the western extremity of the Isle of Wight, in N. Lat. 50. 39., and W. Long. 1. 34. Their origin is attributable to the sea beating on the sharp cliffs which form the W. point of the island, and the same influence is gradually wasting them away; the largest of them, which was 120 feet in height, having been submerged in 1764. They are white, but black at their bases, and curiously streaked throughout with black strata of flints. A lighthouse standing on this extremity of the island rises 715 feet above the sea.

NEEFS, PETER, surnamed "the Elder," an eminent Flemish painter, was born at Antwerp in 1570. He studied under Steenwyck the Elder, and, like his master, directed his attention to the painting of the interior of churches and convents. His delicate finish, exquisite colouring, and correct execution of perspective, soon placed his pictures among the best of their class. The figures which he employed Jan Breughel, Teniers, or other eminent artists, to introduce into his churches, added much to the effect. Neefs died about 1650. His son, called Peter Neefs "the Younger," imitated him both in the selection of subjects and in style, but with no great success.

NEEMUCH, in Hindustan, a town with a British cantonment, in the territory of Gwalior, or possessions of Scindia, situated on the N.W. border of Malwa, at a short distance from the boundary which separates that tract of country from Mewar. Bishop Heber describes the cantonment as a stationary camp of thatched bungalows and other buildings, open on all sides, and surrounded by a fine plain for the performance of military evolutions. Wallich, a later traveller, gives the following account of it:—"The cantonment extends on a slightly elevated ridge, running about N.W. and S.E.; its extreme length is 2½ miles, and the extreme breadth 1 mile. The lines are placed in front, facing to the northward; the regimental officers' quarters behind these; and the Sudder Bazaar and staff to the rear of all. Lines have at various periods been built capable of containing one regiment of native cavalry, one troop of native horse artillery, four regiments of native infantry, and a regiment of irregular horse." A small fort has been constructed by the British as a place of refuge for the families of the military, when called to a distance on duty. The native troops stationed at this place participated in the general mutiny of the Bengal army. The rising took place on the night of the 3d June 1857, when a general massacre of Europeans took place. The work of slaughter was commenced by the artillery, and all the native troops joined heartily in it. A native officer opened

Needles,

the gate of the fort, and gave entrance to the rebels. Having committed the most frightful enormities, and outraged every law of humanity, a large body of the miscreants marched in the direction of Agra. (Some account of their subsequent proceedings will be found under the article NORTH-WESTERN PROVINCES OF BENGAL.) Neemuch is distant 312 miles from Agra, and 371 from Delhi; N. Lat. 24. 27., E. Long. 74. 54.

NEER, ARNOULD, or AART VANDER, "the prince of moonlight painters," was born at Amsterdam in 1619. His paintings soon became remarkable for their fidelity to nature, and for their calm poetical tone. He excelled in representing winter scenes; but his favourite subject was the moon shedding down her silver light upon a sleeping hamlet, in the midst of a few trees on the bank of a smooth-flowing river. These moonlight pieces are found all over Europe, and are marked by a monogram, consisting of A. V. D. N. Neer died in 1683.

NEER, *Eglon Hendrick Vander*, an eminent artist, was the son of the preceding, and was born at Amsterdam in 1643. His first lessons in painting were received from his father. He then became the pupil of Jacob Vanloo, and about the age of twenty followed his teacher to Paris. His principal studies, however, seem to have been the masterpieces of Gaspar Netscher, William Mieris, and Terburg. It was soon apparent that he had caught some of the several excellencies of these famous artists. A more striking feature of his pictures, however, was an elaborateness in detail. On every kind of subject which he painted he employed the careful and minute attention of one who strives to build his reputation on a few highly-finished masterpieces. His pictures of conversational parties are crowded with the most splendid accessories; and owing to the excessive finish of his trees and flowers, his historical pieces ought to be called landscapes, and his landscapes ought to be called garden pieces. Neer died in 1703, at the court of the elector-palatine at Düsseldorf. Specimens of his paintings are to be seen in the Bridgewater collection, and in the collections of Mr Hope and the Marquis of Bute.

NEFF, FELIX, a devoted Swiss missionary, was born at Geneva on the 8th of October 1798. He received his early education chiefly from his widowed mother, who was distinguished for her piety; and occasionally had the benefit of a lesson from some kind pastor of his native canton. The favourite authors of his boyish years were Plutarch and Rousseau; and he took great interest in the study of natural history and mathematics. He was placed at an early age with a florist-gardener in the environs of Geneva, and at the age of seventeen entered the army, that he might no longer be a burden to his poor mother. Here his patient industry and excellent character soon raised him to the rank of serjeant; but his earnest, thoughtful nature becoming greatly impressed with the truths of religion, he was induced in 1819 to exchange the life of a soldier in the garrison of Geneva for that of a Protestant missionary in the wild glens of the High Alps. The first years of his missionary life were spent as a *proposant* or catechist in the cantons of Geneva, Neuchâtel, Berne, and the Pays de Vaud. In 1821 he turned his attention to the destitute district of Grenoble in France, and subsequently to that of Mens in Isère, with the hope of making "recruits," as he was wont to phrase it. He went to England in April 1823, and after obtaining clerical ordination from the Independents there, he returned to the scene of his former labours at Mens. A short time afterwards, we find him among the High Alps, pursuing his noble undertaking with great courage and zeal among the descendants of the Vaudois, in the wild picturesque valleys of Queyras and Freysinières. Here he dedicated temples, organized schools, and laboured incessantly, "by day and night, through wind,

snow, and ice," among those lonely glens and savage mountains, until he broke his health. The baths of Plombières were visited without any permanent effect, and he returned to native Geneva only to die. Small companies of the poor people of the distant Alpine valleys made long journeys on foot through the snow to see their dying pastor; but the spring of 1829 put an end to his sufferings, and sent these devoted ones back to their native wilds in tears. (*The Life of Felix Neff*, by A. Bost, London, 1855.)

NEGAPATAM, a considerable seaport in the south of India, and province of Tanjore. It was formerly well fortified, and had a citadel of a pentagonal form, with wet ditches. It has no considerable trade, but is frequently touched at by ships for refreshments, which are plentiful. The town lies at the north side of the citadel, near which is the mouth of a small river, capable of receiving vessels which draw little water. At the mouth of the river there is a bar, over which the surf breaks with great violence in bad weather, and renders the entrance dangerous. The anchoring place is about 3 miles from the shore, opposite the town, where there is very little current; and to the S.E. of the town, at the distance of 5 miles, there is a shoal about 5 miles in length, having from 3 to 6 fathoms water on it. It was originally a small village, but was fortified and improved by the Portuguese. In 1660 it was taken from them by the Dutch, who strengthened its fortifications, and made it the capital of their settlements on the Coromandel coast, where they established a mint. Under their rule it enjoyed a long period of tranquillity; its trade increased, and it became a very flourishing city. In 1781 it was besieged and taken by the British with about 4000 troops, and was finally ceded to them at the peace of 1783; since which period the fortifications have been neglected, and the trade has been transferred to other places. E. Long. 79. 55., N. Lat. 10. 46.

NEGRAIS, an island, harbour, and cape of the Eastern Peninsula, is situated at the S.W. extremity of the kingdom of Pegu, in N. Lat. 16. 1., E. Long. 94. 12. The island is small, and is now deserted and overgrown with jungle; but the harbour is one of the safest in the Bay of Bengal. In 1687 a settlement was founded here by the British government of Madras, but it was soon after abandoned. In 1751 it was again for a short time occupied by the British; and in 1757 was ceded to them by the Burman emperor; but two years afterwards, the Burmese attacked it, and put to death all the inhabitants who did not succeed in effecting their escape.

NEGROES. See ETHNOLOGY, and AFRICA.

NEGROPONT, or CHALCIS, a town of Greece, capital of Eubœa, is situated on the Euripus, which separates that island from the mainland, and is here at its narrowest point only 40 yards in breadth. It is built in the form of a crescent, touching the sea at each extremity, and surrounding the citadel, or *castro*, as it is termed, which stands on a lofty rock overlooking the straits. The fortifications of the citadel are partly of Venetian and partly of Turkish construction; while the outer walls of the town, which are now in a state of great dilapidation, are Venetian. The streets are narrow, but there are many good houses, especially those built by the Venetians. There is also a Gothic church with square towers; and, as a few Mohammedans still remain in Negropont, one of the mosques is used by them in its former capacity, while the others have been converted into Christian churches. The gate of the citadel is surmounted by the lion of St Mark. In the middle of the straits is a small rocky islet, on which stands a tower; and this is connected with the mainland by a stone bridge about 70 feet long, and with the island by one of wood 35 feet long, with a drawbridge at each end, to allow the passage of ships. The ancient name of the town was *Chalcis*; and it was a place of great importance in antiquity. Strabo

Negro,
Rio.

informs us that it was twice colonized by Ionians from Attica in early times. It soon became one of the greatest commercial towns of Greece, and sent out a large number of colonies to various parts of the world. The peninsula of Chalcidice in Macedonia obtained its name from the number of Chalcidian colonies founded there. Cumæ and Rhegium in Italy, and Naxos, Zancle, and Tauromenium in Sicily, are among the cities which owed their origin to Chalcis. The government was originally in the hands of an aristocracy, called *hippobota*, who were in all probability the proprietors of the rich plain of Lelantum, between Chalcis and Eretria. This plain was claimed by both of these cities; and at an early period a war took place between them, in which Miletus and Samos took part. After the expulsion of the Pisistratidæ from Athens, the Chalcidians joined the Bœotians in a war against that city; but the Athenians, in 506 B.C., invaded the island with a large force, and after a complete victory, divided the lands of the nobles among 4000 Athenian settlers. These, however, retired from the island on its invasion by the Persians in 490 B.C. After the Persian war, Eubœa joined the Athenian confederacy, and continued in that alliance till 445 B.C., when a general insurrection took place in the island against Athens. It was, however, soon reconquered and reduced to subjection by Pericles, and the aristocracy of Chalcis were deprived of their power. In 411 B.C., after the disastrous end of the Athenian expedition to Sicily, the whole of Eubœa again threw off the Athenian yoke, and the bridge across the straits was then first built, in order to secure the communication with Bœotia. The island continued independent for some time, and joined the Theban confederacy against Sparta; but when the Athenian power was again in the ascendant, the cities of Eubœa became once more subject to her supremacy, and were governed by tyrants. About 350 B.C., Callias and Taurosthenes, joint tyrants of Chalcis, wishing to obtain the sovereignty of the whole island, asked the assistance of Philip of Macedon, who readily acceded to their request; but Plutarch, tyrant of Eretria, having applied to the Athenians for aid against this attempt, they sent an army under Phocion, by whom the Chalcidians were defeated. The Macedonian party, however, still retained their power in Chalcis; and soon the influence of Philip was predominant throughout the island. Owing to its strength and position, Chalcis was a place of much importance in the contest for the dominion of Greece which took place after the death of Alexander, and it was frequently taken in these wars. In later times it fell successively into the hands of Antiochus and Mithridates and was finally taken and destroyed by the Romans, by whom Eubœa was included in the province of Achaia. From this time the island continued undisturbed under the power of Rome, and under that of Constantinople after the division of the empire, until the Latin conquest of the East in 1204 A.D. At that time the island came into the hands of the Venetians, who retained possession of it till 1470, when the city of Negropont, as it was then called, was taken by the Turks, and the inhabitants cruelly massacred. In 1688 the Venetians made an unsuccessful attempt to retake the town. Since the Greek revolution, Eubœa has formed part of the modern kingdom of Greece; and as the ancient appellations have been by law restored, Eubœa and Chalcis are now the names by which the island and town are most commonly known. Pop. of the island (1852), 65,299; of the town, 5000.

NEGRO, Rio, a river of South America, forming the boundary between Patagonia and the Argentine Confederation, takes its rise in the Andes by two head-streams, one from the north and the other from the south, and flows eastward to the Atlantic, into which it falls in S. Lat. 41., W. Long. 62. 50., after a course of from 500 to 600 miles.

It is full of small islands and sand-banks; and about the middle of its course it separates into two branches, which inclose an island of considerable size. The river is subject to two annual floods, one of which, in December and January, is occasioned by the melting of the snows of the Andes; and the other, in June and July, by the heavy rains in the interior. The river is about 2 miles broad at its mouth; but at the town of Carmen, about 16 miles from the sea, it does not exceed 300 yards in width. Near its entrance is a bar, over which there are several channels, some of which may be crossed by vessels drawing 11 feet of water. The climate of the district is healthy; and though very warm in summer, ice is frequently formed between the months of April and July. The winds are very variable, and frequently violent. The principal town on the river is Carmen, on the north bank, with a population exceeding 1000.

NEGRO, Rio, one of the principal tributaries of the Amazon, rises in New Granada by two head streams, and flows eastwards till it falls into the Amazon, in S. Lat. 3. 16., W. Long. 59. Its principal affluents are the Cassiquiare, by which it is connected with the Orinoco, the Cababure, Padaviri, and Branco, from the N.; and the Tomo, Zie, Haupes, &c., from the S. and W. In the lower part of its course the river flows through a succession of lakes from 15 to 20 miles broad: at its junction with the Amazon it is about 1½ mile in breadth. The river is flooded during the months of August and September, when it rises about 30 feet above its lowest level. The length is about 1000 miles.

NEGROS, one of the Philippine Islands, lies between N. Lat. 9. 3. and 10. 58., and between E. Long. 122. 28. and 123. 29.; being separated by narrow channels from the islands of Panay on the N.W., and Zebu on the E. It is about 140 miles in length, with an average breadth of 25 miles, and an area estimated at 3827 square miles. A range of mountains traverses the island from N. to S., and it is watered by numerous rivers. The interior is little known; it contains large forests abounding in beautiful and valuable timber. Coffee, tobacco, and rice are cultivated; and palms and cocoa-nut trees also grow on the island. Wax, honey, palm oil, rock-crystal, pearls, sulphur, &c., are among the productions of Negros. The climate is generally healthy; but the island is subject to earthquakes. The inhabitants of the interior are rude and uncivilized; and there are few Spanish settlers. The governor resides at Timamailan, where there is a church and a small harbour. Pop. of the island, 35,622.

NEHEMIAH, a distinguished Jewish patriot, and author of the book of Scripture which bears his name, was the son of Hachaliah (Neh. i. 1), and brother of Hanani (vii. 2). His genealogy is unknown. Some think, however, that he was of priestly descent, because his name appears at the head of a list of priests in chap. x. 1-8; but it is obvious, from chap. ix. 38, that he stands there as a prince, and not as a priest. Others with some probability infer, from his station at the Persian court, and the high commission he received, that he was, like Zerubbabel, of the tribe of Judah and of the house of David (Carpzov, *Introductio*, &c., p. i. 339). While Nehemiah was cup-bearer to Artaxerxes Longimanus in the royal palace of Shushan, 444 B.C., he learned the mournful and desolate condition of the colony returned to Judæa. This filled him with such deep concern, that his sad countenance revealed to the king his sorrow of heart, which induced the monarch to send him with full powers to rebuild the wall of Jerusalem, and "to seek the welfare of the children of Israel." Nehemiah reached Jerusalem B.C. 444, and remained there till B.C. 432 (v. 14). The principal work then accomplished by him was the repairing of the city wall, which was done "in fifty and two days" (vi. 15), notwithstanding many discouragements and difficulties, caused chiefly by Sanballat, a

Nehemiah.

Nehemiah. Moabite of Horonaim, and Tobiah, an Ammonite, who were leading men in the rival and unfriendly colony of Samaria (iv. 1-3), as well as by certain of the Jewish people themselves. Nehemiah, however, displayed great firmness, sagacity, and zeal; and the completion of the wall was most joyously celebrated by a solemn dedication under his own direction (xii. 27-43).

Having succeeded in fortifying the city, he turned his attention to other measures, in order to secure its good government and prosperity (vii. 1-3; xii. 44-47; viii. 1-12; viii. 13-18; ix.; x.; vii. 4; also xi. 1-19). In these important public proceedings, Nehemiah enjoyed the assistance of Ezra, who had gone up to Jerusalem a number of years previously. (See EZRA.)

At the close of his successful administration Nehemiah returned to Babylon in the year 432 B.C., and resumed, as some think, his duties as royal cup-bearer. He returned, however, to Jerusalem, probably about 424 B.C., where his services became again requisite, in consequence of abuses that had crept in during his absence. (See Prideaux, i. 520; Jahn, *Einleitung ins A. Test.* ii. 288; Winer, *Realwörterbuch*; also, Hävernick, *Einleitung ins A. Test.* ii. 324.) The duration of this second administration, during which he effected many important reforms, both social and religious, cannot be accurately determined, but it probably lasted ten years, namely, from 424 to 413 B.C. It is not unlikely that he remained at his post till about the year 405 B.C., towards the close of the reign of Darius Nothus, who is mentioned in chap. xii. 22. At this time Nehemiah would be between sixty and seventy years old, if we suppose him (as most do) to have been only between twenty and thirty when he first went to Jerusalem. That he lived to be an old man is thus quite probable from the sacred history. Josephus (*Antiq.* xi. 5, 6) states that he died at an advanced age; but of the place and year of his death nothing is known. Besides the account in Josephus, there are some honourable notices of Nehemiah in the Apocrypha.

NEHEMIAH, *The Book of*, was anciently connected with Ezra, as if it formed part of the same work (Eichhorn, *Einleitung*, ii. 627) (See EZRA.) From this circumstance some ancient writers were led to call this book the 2d book of Ezra, and even to regard that learned scribe as the author of it (Carpzov, *Introductio*, &c., p. 336). There can, however, be no reasonable doubt that it proceeded from Nehemiah, for its style and spirit, except in one portion, are wholly unlike Ezra's.

The canonical character of Nehemiah's work is established by very ancient testimony. It is not expressly named, however, by Melito of Sardis (A.D. 170) in his account of the sacred writings; but this creates no difficulty, since he mentions Ezra, of which, as we have seen, Nehemiah was then considered a part. The work is properly a collection of notices of some important transactions that happened during the first year of Nehemiah's government, with a few scraps from his later history. The contents appear to be arranged in chronological order, with the exception perhaps of ch. xii. 27-43, where the account of the dedication of the wall seems out of its proper place: we might expect it rather after ch. vii. 1-4, where the completion of the wall is mentioned. While the book as a whole is considered to have come from Nehemiah, it consists in part of compilation. He doubtless wrote the greater part himself, but some portions he evidently took from other works. It is allowed by all that he is, in the strictest sense, the author of the narrative from ch. i. to ch. vii. 5 (Hävernick, *Einleitung*, ii. 304). The account in ch. vii. 6-73 is avowedly compiled, for he says in ver. 5, 'I found a register,' &c. This register we actually find also in Ezra ii. 1-70: hence it might be thought that our author borrowed this part from Ezra; but it is more likely, from their obvious discrepancies, that

they both copied from public documents, such as "the book of the chronicles" mentioned in Neh. xii. 23, which were not themselves harmonious. The exegetical helps for the explanation of this book are chiefly Poole's *Synopsis*, Lond. 1669-76; Jo. Clerici, *Comm. in Lib. Historicos V. T.*, Amst. 1708; Maurer, *Comment. Crit. Grammat. in V. T.*, vol. i., Lips. 1833; Strigellii, *Scholia in Nehem.*, Lips. 1575; and Rambach, *Annotationes in Librum Nehemias*, Halæ, 1751.

NEHRUNG, CURISCHE, a long strip of land in Prussia, in the province of East Prussia, about 60 miles in length, and nowhere above 3 in breadth, separating the lagoon called the Curische Haff from the Baltic. It consists of sand, and is entirely barren. Several villages have been buried by the gradual accumulation of the sand.

NEHRUNG, *Frische*, a similar sandy strip in West Prussia, between the Frische Haff and the Baltic.

NEILGHERRIES, in Hindustan, a range of mountains in the presidency of Madras, situated between N. Lat. 11. 10. and 11. 35., E. Long. 76. 30. and 77. 10. This remarkable range is connected on its western side, where its summits bear the name of the Koondahs, with the Siadri branch of the Western Ghauts, here terminating in a southern face of lofty and perpendicular precipices, and forming the north side of the great Palghat valley or depression, which, extending east and west with a breadth of about 20 miles, affords an easy communication between the Carnatic and Malabar. The general outline of the Neilgherry group approaches to a triangle, having the side which may be regarded as the base extending nearly from N. to S., and facing Malabar; its north side extending E. and W. facing Mysore; and the remaining side extending from N.E. to S.W., towards the British district of Coimbatore. From the last-mentioned district, the Neilgherries rise in a vast precipitous mass to the height of from 5000 to 7000 feet, and the aggregate of the group is popularly divided into three ranges,—the Neddimullah on the N., the Koondah on the S., and the central or principal range, rising to the summit of Doda-betta, the highest in the group, and having an elevation of 8760 feet above the level of the sea, being the greatest in India south of the Himalaya. Owing to the great elevation of the various summits, and the consequent rarefaction of its atmosphere, the district, although distant only 11° from the equator, enjoys a climate famed for its salubrity, and the remarkable evenness of its seasons. The temperature, which falls in the coldest month of the year to the freezing point, seldom in the hottest reaches 75° in the shade. The great importance of this group lies in its sanatory stations for the re-establishment of health in those who have suffered from the heat of the climate in less elevated regions. The principal of these stations is Ootacamund, the two minor ones Coonoor and Kotageri. This tract of territory was transferred to the British on the downfall of Tippoo Sultan in 1799. (R. Baikie's *Neilgherries*.)

NEILSTON, a village and parish of Scotland, in the county of Renfrew, is situated on the Levern, 4 miles S. of Paisley, and 9 W.S.W. of Glasgow. It has an Established, a Free, and a United Presbyterian church, several schools, and a mechanics' institute. There are here also cotton-mills and bleachfields; and four fairs are held annually. Pop. (1851) of village, 2075; of parish, 12,233.

NEISSE, a town of Prussia, province of Silesia, on both sides of a river of the same name, 47 miles S.S.E. of Breslau. It is well built, surrounded by walls, and strongly fortified. There are three gates; and the town contains several fine public buildings. The episcopal palace is an ancient edifice, and is memorable for the meeting between Frederic II. and the Emperor Joseph II., which took place here in 1769. There are also two Protestant and several Roman Catholic churches, a grammar school, an industrial school, two hospitals, an establishment for superannuated

Nehrung
||
Neisse.

Nejin
Nelson.

Roman Catholic priests, large powder-mills, barracks, and arsenals. Cotton is manufactured here, and a considerable trade is carried on in yarn and building stone. A weekly market for yarn, and an annual fair, are held here. Pop. (1849), 17,164.

NEJIN, or NIESHIN, a town of Russia, in the government of Tchernigov, stands on the Oster, 49 miles S.E. of Tchernigov, and 475 S.W. of Moscow. It is well built, and surrounded by earthen ramparts; and contains a castle, a cathedral, numerous other churches, a convent, a school, and an hospital. There are manufactures of soap, leather, silks, perfumes, confectionary, *liqueurs*, &c. The town has also a considerable trade, the intercourse between the ports on the Baltic and Moldavia, Wallachia, and the Crimea being carried on through it. Three annual fairs are held here, and largely attended. Pop. (1849) 17,981.

NEKO, or NECHO, a king of Egypt who flourished in the fifth century B.C. (See EGYPT.)

NELLORE, in Hindustan, a town within the presidency of Madras, on the right bank of the River Penna, 18 miles from the spot where it falls into the Bay of Bengal. The town is irregularly built, and in places rather crowded and confined; but there are some good streets occupied by the better classes, and on the whole, for a native town, it is tolerably clean and airy. The population is estimated at 20,000; distant N. from Madras 100 miles; N. Lat. 14. 27., E. Long. 80. 2. The British district, of which this town is the chief place, is bounded on the N. by Guntoor, on the E. by the Bay of Bengal, on the S. by Arcot, and on the W. by Cuddapah. It lies between N. Lat. 13. 55. and 16., E. Long. 79. 8. and 80. 21. The area, according to official return, is 7930 square miles, and the population 935,690.

NELSON, HORATIO, Lord Viscount, the son of Edmund and Catherine Nelson, was born on the 29th of September 1758, at the parsonage-house of Burnham-Thorpe, a village in the county of Norfolk, of which his father was rector. The maiden name of his mother was Suckling; her grandmother was an elder sister of Sir Robert Walpole, and the subject of this notice was named after the first Earl of Orford. Mrs Nelson died in 1767, leaving eight out of eleven children. Upon this occasion her brother, Captain Maurice Suckling, of the navy, visited Mr Nelson, and promised to take care of one of the boys. Three years afterwards, when Horatio was only twelve years of age, and with a constitution naturally weak, he applied to his father for permission to go to sea with his uncle, recently appointed to the *Raisonnable* of sixty-four guns. The uncle was accordingly written to, and gave a reluctant consent to the proposal. "What," said he, in reply, "has poor Horatio done, who is so weak, that he should be sent to rough it out at sea? But let him come; and the first time we go into action a cannon-ball may knock off his head, and provide for him at once." The *Raisonnable*, on board of which he was now placed as a midshipman, was soon afterwards paid off, and Captain Suckling removed to the *Triumph*, of seventy-four guns, then stationed as a guard-ship in the Thames. This, however, was considered as too inactive a life for a boy, and Nelson was therefore sent a voyage to the West Indies in a merchant ship. "From this voyage I returned," he tells us in his *Sketch of my Life*, "to the *Triumph* at Chatham in July 1772; and if I did not improve in my education, I returned a practical seaman, with a horror of the royal navy, and with a saying then constant with the seamen, 'Aft, the most honour; forward, the better man.'" While in connection with this guardship, he had the opportunity of becoming a skilful pilot, an acquirement which he afterwards had frequent occasion to turn to account.

Not many months after his return, his inherent love of enterprise was excited by hearing that two ships were fitting out for a voyage of discovery towards the North Pole.

From the difficulties expected on such service, these vessels were to take out none but effective men, instead of the usual number of boys. This, however, did not deter Nelson from soliciting to be received, and by his uncle's interest he was admitted as cockswain under Captain Lutwidge, the second in command. The voyage was undertaken in consequence of an application from the Royal Society; and the Honourable Captain John C. Phipps, eldest son of Lord Mulgrave, volunteered his services to command the expedition. The *Racehorse* and *Carcass*, bombs, were selected as the strongest ships, and the expedition sailed from the Nore on the 4th of June 1773, and returned to England in October. During this voyage Nelson gave several indications of that daring and fearless spirit which ever afterwards distinguished him.

The ships were paid off shortly after their return, and the youth was then placed by his uncle with Captain Farmer in the *Seahorse*, of twenty guns, which was about to sail for the East Indies in the squadron of Sir Edward Hughes. In this ship he was rated as a midshipman, and attracted attention by his general good conduct. But when he had been about eighteen months in India, he felt the effects of the climate of that country, so perilous to European constitutions, and became so enfeebled by disease that he lost for a time the use of his limbs, and was brought almost to the brink of the grave. He embarked for England in the *Dolphin*, Captain Pigot, with a body broken down by sickness, and spirits which had sunk with his strength. But his health materially improved during the voyage, and his native air speedily repaired the injury it had sustained. On the 8th of April 1777 he passed, with much credit to himself, his examination for a lieutenancy, and next day received his commission as second lieutenant of the *Lowestoffe*, of thirty-two guns, then fitting out for Jamaica. In this frigate he cruised against the American and French privateers which were at that time harassing our trade in the West Indies; distinguished himself on various occasions by his activity and enterprise; and formed a friendship with his captain, Locker, of the *Lowestoffe*, which continued during his life. Having been warmly recommended to Sir Peter Parker, the commander-in-chief upon that station, he was removed into the *Bristol* flag-ship, and soon afterwards became first lieutenant. On the 8th of December 1788 he was appointed commander of the *Badger* brig, in which he rendered important assistance in rescuing the crew of the *Glasgow*, when that ship was accidentally set on fire in Montego Bay, Jamaica. On the 11th of June 1799 he obtained the rank of post-captain, and with it the command of the *Hinchinbrook* of twenty-eight guns. As Count d'Estaing, with a fleet of 125 sail, men-of-war and transports, and a reputed force of 25,000 men, now threatened Jamaica from St Domingo, Nelson offered his services to the admiral and governor-general, Dalling, and was appointed to command the batteries of Fort-Charles at Port-Royal, the most important post in the island. D'Estaing, however, attempted nothing with this formidable armament, and the British general was thus left to execute a design which he had formed against the Spanish colonies. This project was to take Fort San Juan, situated upon the river of that name, which flows from Lake Nicaragua into the Gulf of Mexico; to make himself master of the lake itself, and of the cities of Granada and Leon; and thus to cut off the communication between the northern and southern possessions of Spain in America. Nelson was appointed to the command of the naval department, and distinguished himself greatly in the siege of Fort San Juan and in taking the island of St Bartolomeo. Pestilence, however, decimated the crew of the *Hinchinbrook*; and her gallant young commander, prostrated by sickness, was compelled to return to England. He was taken home in the *Lyon*, by Captain, afterwards

Nelson.

Nelson.

Admiral, Cornwallis, to whose care and kindness he believed himself indebted for the preservation of his life. In three months, however, his health was so far re-established that he applied for employment; and being appointed to the *Albemarle*, of twenty-eight guns, he was sent to the North Seas, and kept there cruising during the whole winter, which he did not at all relish. In this cruise, however, he gained a considerable knowledge of the Danish coast and its soundings. On his return he was ordered to Quebec, and during the voyage the *Albemarle* had a narrow escape from four French sail of the line and a frigate, which, having come out of Boston, gave chase to her. Confiding in his own skill and pilotage, Nelson, perceiving that they gained on him, boldly ran among the numerous shoals of St George's Bank, and thus escaped. In October 1782 he sailed from Quebec with a convoy of transports for New York, where he joined Lord Hood, and accompanied him to the West Indies. At the peace of 1783, the *Albemarle* returned to England, and was paid off.

After his arrival in England, Nelson, finding it prudent to economize his half-pay during the peace, went to St Omer, where he remained till the spring of the following year. On his return, he was appointed to the *Boreas*, of twenty-eight guns, which had been ordered to the Leeward Islands as a cruiser. Whilst on this station, where he found himself senior captain, and consequently second in command, he evinced the utmost zeal and activity in protecting British interests, and in causing the Navigation Act to be respected, especially by the Americans, who had attempted, under various pretences, to establish an independent commerce with the West India Islands; a line of conduct which involved him in much trouble, without procuring him reward or even acknowledgment—the thanks of the Treasury having been transmitted to the commander-in-chief, who had thwarted instead of encouraging him in the discharge of an arduous and important duty. On the 11th of March 1787, Nelson married the widow of Dr Nisbet, a physician, and daughter of Herbert, the president of the island of Nevis. The *Boreas* returned to England in June, but was not paid off till the end of November, having been kept nearly five months at the Nore as a slop and receiving ship. Nelson was still in a very precarious state of health; and this treatment, whether proceeding from intention or neglect, excited in his mind the strongest indignation. His resentment, however, was appeased by the favourable reception which he met with at court, when presented to his Majesty by Lord Howe; and having fully explained to that nobleman the grounds upon which he had acted, he retired to enjoy the pleasures of domestic happiness at the parsonage-house at Burnham-Thorpe, which his father had given him as a residence. But the vexatious affair of the American captures was not yet terminated. He was harassed with threats of prosecution, and, in his absence on some business, a writ or notification was served on his wife, upon the part of the American captains, who now laid their damages at £20,000. When presented with this paper, his indignation was excessive; and he immediately wrote to the Treasury, that unless he was supported by government he would leave the country. "If sixpence would save me from prosecution," said he, "I would not give it." The answer he received, however, quieted his fears; he was told to be under no apprehension, for he would assuredly be supported; and here his disquietude upon this subject seems to have ended.

At the commencement of the French war, it was judged expedient again to employ Nelson; and on the 30th of

Nelson.

January 1793 he was appointed to the *Agamemnon*, of sixty-four guns, and placed under the orders of Lord Hood, then holding the chief command in the Mediterranean fleet. Being sent to Corsica with a small squadron, to co-operate with Paoli and the party opposed to France, he undertook the siege of Bastia, and in a short time reduced it. The place capitulated on the 19th of May 1794. He next proceeded in the *Agamemnon* to co-operate with General Sir Charles Stuart in the siege of Calvi. Here Nelson had less responsibility than at Bastia; he was acting with a man after his own heart, who slept every night in the advanced battery. Here Nelson received a serious injury. A shot having struck the ground near him, drove the sand and small gravel into one of his eyes. He spoke of it lightly at the time, and in fact suffered it to confine him only one day; but the sight of the eye was nevertheless lost. After the fall of Calvi his services were, by a strange omission, altogether overlooked, and his name was not even mentioned in the list of wounded. Nelson felt himself not only neglected, but wronged. "They have not done me justice," said he; "but never mind, I'll have a gazette of my own." And on another occasion the same second-sight of glory led him to predict that one day or other he would have a long gazette to himself. "I feel," said he, "that such an opportunity will be given me. If I am in the field of glory, I cannot be kept out of sight."

Lord Hood now returned to England, and the command devolved upon Admiral Hotham. Tuscany had now concluded peace with France; Corsica was in danger; Genoa was threatened; and the French, who had not yet been taught to feel their inferiority upon the seas, openly braved us on that element. Having a superior fleet in the Mediterranean, they now sent it out with express orders to seek the English and engage them. In the action which followed between the English fleet under Admiral Hotham, and that which had come out from Toulon, Nelson greatly distinguished himself, manœuvring and fighting his ship with equal ability and determination; and when the action was renewed the following day, he had the honour of hoisting the English colours on board of the *Ça Ira* and the *Censeur*, which both struck to him, and were the only ships of the enemy taken on that occasion.¹ About this time Nelson was made colonel of marines, a mark of approbation which he had rather wished for than expected; and soon afterwards the *Agamemnon* was ordered to Genoa to co-operate with the Austrian and Sardinian forces. This was indeed a new line of service, imposing multifarious duties, and involving great responsibility; yet it was also one for which Nelson had already evinced a singular aptitude, and in which, had he been at all seconded by the land forces, his assistance would have led to important results. Through the gross misconduct, however, of the Austrian general, Devins, the allies were completely defeated by an army of boys, and the French obtained possession of the Genoese coast from Savona to Voltri, thus intercepting the direct communication between the Austrian army and the English fleet. After this disgraceful affair, the *Agamemnon* was recalled, and sailed for Leghorn to refit, being literally riddled with shot, and having all her masts and yards seriously damaged.

Sir John Jervis having arrived to take the command in the Mediterranean, Nelson sailed from Leghorn in the *Agamemnon*, which had now been repaired, and joined the admiral in St Fiorenzo Bay. When the French took possession of Leghorn, he blockaded that port, and landed a force in the Isle of Elba to secure Porto Ferrajo. Soon

¹ Nelson urged the admiral to pursue the enemy, and follow up his advantage to the utmost; but the latter replied, "We must be contented; we have done very well." The captain of the *Agamemnon* did not understand such timid reasoning. "Had we taken ten sail," said he, "and allowed the eleventh to escape when it had been possible to have got at her, I could never have called it well done." He adds, that if his advice had been followed, they would have had such a day as the annals of England never produced.

Nelson.

afterwards he took the island of Capraja; and the British cabinet having resolved to evacuate Corsica, he ably performed this humiliating service. He was then ordered to hoist his broad pennant on board of the *Minerve* frigate, Captain George Cockburn, and to proceed with the *Blanche* to Porto Ferrajo, and bring away the troops and stores left at that place. On his way thither he fell in with two Spanish frigates, the *Sabina* and *Ceres*, the former of which, after an action of three hours, during which the Spaniards lost 164 men, struck to the *Minerve*. The *Ceres*, however, had got off from the *Blanche*; and as the prisoners had hardly been conveyed on board of the *Minerve* when another enemy's frigate came up, Nelson was compelled to cast off the prize and go a second time into action. But after a short trial of strength, this new antagonist wore and hauled off; and as a Spanish squadron of two sail of the line and two frigates now came in sight, the commodore made all sail for Porto Ferrajo, whence he soon returned with a convoy to Gibraltar. Off the mouth of the Straits he fell in with the Spanish fleet, and reaching the station off Cape St Vincent on the 13th of February 1797, he communicated this intelligence to Sir John Jervis, by whom he was now directed to shift his broad pennant on board the Captain, of seventy-four guns. Before sunset the signal was made to prepare for action, and to keep in close order during the night; and at daybreak on the 14th the enemy were in sight. The British force consisted of two ships of 100 guns, two of 98, two of 90, eight of 74, and one of 64, with four frigates, a sloop, and a cutter; the Spaniards had one ship of 136 guns, six of 112 guns each, two of 84, and eighteen of 74, with ten frigates and a brig. The admiral, Sir John Jervis, made signal to tack in succession. Nelson, whose station was in the rear of the British line, perceiving that the Spaniards were bearing up before the wind, with an intention of forming line and joining their separated ships, or of avoiding an engagement, disobeyed the signal without a moment's hesitation, and ordered his ship to be wore. This at once brought him into action with seven of the enemy's ships, four of which were first-rates. After a desperate conflict, in which Nelson was nobly supported by Troubridge in the *Culloden* and by Collingwood in the *Excellent*, the *Salvador del Mundo* and *San Isidro* dropped astern, and the *San Josef* fell on board the *San Nicolas*. The Captain being now incapable of further service, either in the line or in chase, Nelson directed the helm to be put a-starboard, and calling the boarders, ordered them to board. The *San Nicolas* was carried after a short struggle, Nelson himself boarding her through the cabin windows. The *San Josef* was instantly boarded from the *San Nicolas*, the gallant little commodore leading the way, and exclaiming, "Westminster Abbey or victory!" This was the work of an instant; but before Nelson could reach the quarter-deck of the Spanish ship, an officer looked over the rail and said they surrendered. This daring achievement was effected with comparatively small loss, and Nelson himself received only a few bruises. The Captain, however, had suffered severely in the action. She had lost her fore-topmast; not a sail, shroud, nor rope was left; her wheel had been shot away; and a fourth part of the loss sustained by the whole squadron had fallen upon that single ship. As soon as the action was discontinued, Nelson went on board the admiral's ship. Sir John Jervis

received him with open arms, and said he could not sufficiently thank him. For this victory the commander-in-chief was rewarded with a peerage and the title of Earl St Vincent; whilst Nelson, who, before the action was known in England, had been advanced to the rank of rear-admiral, was knighted, and received the insignia of the Bath, and a gold medal from his sovereign.

Nelson.

In April 1797 Sir Horatio Nelson, having hoisted his flag as rear-admiral of the blue, was sent to bring away the troops from Porto Ferrajo; and having performed this service, he shifted his flag to the *Theseus*, a ship which had taken part in the mutiny in England. Whilst in the *Theseus* he was employed in the command of the inner squadron at the blockade of Cadiz. During this service his personal courage was eminently signalized. In a night attack upon the Spanish gun-boats (3d July 1797), his barge was assailed by an armed launch, carrying twenty-six men, whilst he had with him only the usual complement of ten men and the cockswain, besides Captain Freemantle. After a severe conflict, hand to hand, eighteen of the enemy were killed, all the rest wounded, and the launch taken. Twelve days after this rencontre, Nelson sailed at the head of an expedition against Teneriffe. It having been ascertained that a homeward-bound Manila ship had recently put into Santa Cruz, the expedition was undertaken in the hope of capturing this rich prize. But it was not fitted out upon the scale which Nelson had proposed; no troops were embarked; and although the attack was made with great intrepidity, the attempt failed. The boats of the squadron being manned, a landing was effected early in the night, and Santa Cruz taken and occupied for about seven hours; but the assailants, finding it impracticable to storm the citadel, were obliged to prepare for retreat, which they effected without molestation, agreeably to stipulations which had been made with the Spanish governor by Captain Troubridge, whose firmness and presence of mind were conspicuously displayed on this occasion. The total loss of the English in killed, wounded, and drowned, amounted to 250. Nelson himself was amongst the wounded, having, in stepping out of the boat to land, received a shot through the right elbow, which shattered the whole arm, and rendered amputation necessary. Nelson was now obliged to return to England, where honours awaited him sufficient to cheer his mind amidst the sufferings occasioned by the loss of his arm. Letters were addressed to him by the first lord of the Admiralty and the Duke of Clarence; the freedom of the cities of London and Bristol was transmitted to him; he was invested with the Order of the Bath; and he also received a pension of L.1000 a year.¹ His sufferings from the lost limb, however, were long and painful. In April 1798 he had so far recovered, however, as to hoist his flag on board the *Vanguard*, and was ordered to rejoin Earl St Vincent. Immediately on his arrival, he was despatched to the Mediterranean with a small squadron, to ascertain, if possible, the object of the great expedition which was then fitting out at Toulon. He sailed from Gibraltar on the 9th of May for the Mediterranean, with three seventy-fours, four frigates, and a sloop of war. On the 19th the squadron reached the Gulf of Lyons; and on the 22d a violent storm inflicted very serious injury on the *Vanguard*; but after extraordinary exertions, the *Vanguard* was refitted in four

¹ The memorial which, as a matter of course, he was called upon to present on this occasion, exhibited an extraordinary catalogue of services performed during the war. It is dated "October 1797," and addressed "to the King's most excellent Majesty." It stated, that he had been in four actions with the fleets of the enemy, and in three actions with frigates, in six engagements against batteries, in ten actions in boats employed in cutting vessels out of harbour or in destroying them, and in taking three towns; that he had served on shore with the army four months, and commanded the batteries at the sieges of Bastia and Calvi; that he had assisted at the capture of seven sail of the line, six frigates, four corvettes, and eleven privateers of different sizes; that he had taken and destroyed nearly fifty sail of merchant-vessels, and had actually been engaged against the enemy upwards of one hundred and twenty times; in which services he had lost his right eye and right arm, and had been severely wounded and bruised in his body. This memorial alone, apart from the splendid additions which he afterwards made to it, is perhaps without a parallel in our naval history.

Nelson. days, and he received a reinforcement of ten ships of the line and one of fifty guns, under the command of Commodore Troubridge. Baffled in his attempts to get sight of the French fleet, he kept scouring the Mediterranean waters under a press of sail night and day for nearly two months, till, on the 1st of August 1798, he came in sight of Alexandria, and at four in the afternoon descried the French fleet. For several days previous to this the admiral had scarcely taken either food or sleep. He now ordered his dinner to be served, whilst preparations were making for battle; and when his officers rose from table to repair to their several stations, he said to them, "Before this time to-morrow I shall have gained a peerage, or Westminster Abbey."

Brueys, the admiral of the French fleet, had moored his ships in Aboukir Bay, in a strong and compact line of battle; the headmost vessel being close to a shoal on the north-west, and the rest of the fleet forming a kind of curve along the line of deep water, so as not to be turned by any means on the south-west. The advantage of numbers, both in ships, guns, and men, was in favour of the French. They had thirteen ships of the line and four frigates, carrying 1196 guns, and 11,230 men. The English had the same number of ships of the line, and one 50-gun ship, carrying in all 1012 guns and 8068 men. The English ships were all seventy-fours; the French had three 80-gun ships, and one three-decker of 120 guns. Nelson, according to the preconceived plan of attack, resolved to keep entirely on the outer side of the French line, and to station his ships, as far as he was able, one on the outer bow, and another on the outer quarter, of each of the enemy's, thus doubling on a certain portion of their line.¹ The battle commenced at half-past six o'clock, a little before sunset. As the squadron advanced, the enemy opened a steady fire from the starboard side of their line into the bows of the leading British ships. It was received in silence, whilst the men on board of each ship were employed aloft in furling the sails, and below in tending the braces and making ready for anchoring; a proceeding which told the enemy that escape was impossible. Four ships of the British squadron, having been detached previously to the discovery of the French fleet, were at a considerable distance when the battle commenced, and on coming up, the Culloden, the foremost of these ships, suddenly grounded in the darkness, and, notwithstanding the greatest exertions, could not be got off in time to bear a part in the action. The first two ships of the French line had been dismasted within a quarter of an hour after the commencement of the action; and the others had suffered so severely that victory was already certain. At half-past eight o'clock the third, fourth, and fifth were taken possession of. In the meantime Nelson had received a severe wound on the head from a langridge shot, which cut a large flap of skin from the forehead, and occasioned such an effusion of blood that the injury was at first believed to be mortal. But when the surgeon came to examine the wound, he found that the hurt was merely superficial, and requested that the admiral would remain quiet. Nelson, however, could not rest, and having called for his secretary, had begun to dictate his despatches, when suddenly a cry was heard upon deck that L'Orient was on fire. In the confusion, he found his way up unassisted and unnoticed, and having appeared on the quarter-deck, immediately gave orders that boats should be sent to the relief of the enemy. It was about

Nelson. ten minutes after nine o'clock when the fire broke out in L'Orient. Brueys was dead. He had received three wounds, yet would not leave his post; and when a fourth cut him almost in two, he desired to be left to die upon deck. In the meanwhile the flames soon mastered the devoted ship, and by the light of the conflagration, the situation of both fleets could be perceived, their colours being clearly distinguishable. About ten o'clock the ship blew up with a tremendous explosion, which was followed by a pause not less awful. The firing immediately ceased; and the first sound which broke the silence was the dash of her shattered masts and yards falling into the water from the vast height to which they had been projected by the explosion.² The combat recommenced with the ships to leeward of the centre, and continued till about three in the morning. Of thirteen sail of the line, nine were taken, two burnt, and two escaped; and of four frigates, one was burnt and another sunk. In short, it was a conquest rather than a victory. The French fleet had been annihilated; and if the English admiral had been provided with small craft, nothing could have prevented the destruction of the store-ships and transports in the harbour of Alexandria.

Nelson was now at the very summit of glory. Congratulations, rewards, and honours were showered upon him by all the foreign states and powers to which his victory promised a respite from French aggression. In his own country he was created Baron Nelson of the Nile and of Burnham-Thorpe, with a pension of L.2000 a year for his own life and those of his two immediate successors. A grant of L.10,000 was voted to Nelson by the East India Company; the Turkish company presented him with a piece of plate; the city of London bestowed honorary swords on the admiral and his captains; and the thanks of the Parliament and gold medals were voted to him and to all the captains engaged in the action. In the distribution of rewards he was particularly anxious that the captain and first lieutenant of the Culloden should not be passed over because of their misfortune. "It was Troubridge," said he, in addressing the Admiralty, "who equipped the squadron so soon at Syracuse; it was Troubridge who exerted himself for me, after the action; it was Troubridge who saved the Culloden, where none that I know in the service would have attempted it."

Having made the necessary arrangements in regard to the prizes, and left a squadron before Alexandria, Nelson stood out to sea on the seventeenth day after the battle, and early on the 22d of September appeared in sight of Naples, where the Culloden and Alexander had preceded him, and given notice of his approach. Here he was received with every demonstration of joy and triumph, both by the royal family and the people; and it was here he formed that unfortunate connection with Lady Hamilton which exercised so baneful an influence on the rest of his life. The state of Naples at this period was deplorable. The king, like the rest of his race, was passionately fond of field sports, and cared for almost nothing else. The queen had all the vices of the House of Austria, with little to mitigate and nothing to ennoble them. The people were sunk in ignorance, and debased by misgovernment; at once turbulent and cowardly, ferocious and indolent, irreligious and fanatical. Nelson was fully sensible of the depravity and weakness of all by whom he was surrounded; yet, seduced by the blandishments of the queen, the flatteries of the court, and the pernicious

¹ A claim has been more than once put forward on behalf of Captain Foley of the Goliath (afterwards Admiral Sir Thomas Foley, G.C.B.), as having the merit of suggesting this mode of attack; but after carefully examining the evidence brought forward in support of this claim, Sir N. Harris Nicolas, in his edition of Nelson's *Dispatches*, vol. iii., p. 62, &c., is inclined to think that it is unfounded.

² To remind the sea-king of his mortality amid the torrents of praise and adulation which were poured upon him after the victory, an eccentric idea occurred to Captain Hallowell of the Swiftsure, of presenting his chief with a coffin made of part of L'Orient's mainmast. Nelson set great store by this present, and was actually buried, as the gallant captain of the Swiftsure desired, "in one of his own trophies." (Nelson's *Dispatches*, &c., by Sir N. H. Nicolas, vol. iii., p. 88, &c.)

Nelson.

influence which Lady Hamilton now began to exercise over his mind, he suffered himself to be implicated in transactions which, to say the least of it, were not calculated to bring honour to his country, or to heighten his own fame. The defeat of Mack at Castellana, and the advance of the French towards Naples, were followed by the flight of the royal family, who were conveyed by Nelson to Palermo. After this an armistice was signed (10th of January 1799), by which the greater part of the kingdom was given up to the enemy; and this cession necessarily led to the loss of the whole. Naples was occupied by the French under Championnet, and the short-lived Parthenopean republic soon afterwards established. But the successes of the allies in Italy speedily changed the face of affairs, and prepared the way for the restoration of the exiled monarch.

Relying on the diminished numbers of the enemy, whose force had been greatly reduced, the royalists took the field, and Cardinal Ruffo appeared at the head of an armed rabble, which he called the Christian army. Captain Foote, in the *Seahorse*, with some Neapolitan frigates, and a few smaller vessels, was ordered to co-operate with this force, and to give it all the assistance in his power. Ruffo, advancing without any plan, but ready to take advantage of any accident which might occur, now approached Naples. Fort St Elmo, which commands the city, was garrisoned by French troops; but the castles of Uovo and Nuovo, commanding the anchorage, were chiefly defended by the Neapolitan "patriots," the leading men amongst them having taken shelter there. As the possession of these castles would greatly facilitate the reduction of Fort St Elmo, Ruffo proposed to the garrison to capitulate, on condition that their persons and property should be respected, and that they should at their own option, either be sent to Toulon or remain at Naples, without being molested in their persons. These terms were accepted, and the capitulation was signed by the cardinal, the Russian and Turkish commanders, and also by Captain Foote as commanding the British force. But Nelson, who soon afterwards arrived in the bay with a large fleet, made a signal to annul the treaty, declaring that he would grant to rebels no other terms than those of unconditional submission; and notwithstanding the strenuous opposition of the cardinal, the garrisons of the castles were delivered over as rebels to the vengeance of the Sicilian court. This questionable transaction was followed by the execution of Caraccioli. This aged prince, a man who hitherto had borne a high character, and who was a commodore in the Neapolitan navy, had, from some motive or other, joined the enemy; and after being tried by a court-martial of Neapolitan officers, assembled on board the British flag-ship, was found guilty, and sentenced to death. This sentence Lord Nelson ordered to be carried into execution the same evening, on board of the Sicilian frigate *La Minerva*. As a reward for these services, which have, in the judgment of many, left a blot on the scutcheon of the great admiral, Nelson received from the Sicilian court a sword splendidly enriched with diamonds,

in addition to the dukedom of Bronté, with a domain worth about L.3000 a year.¹

Nelson.

After the appointment of Lord Keith to the chief command of the fleet in the Mediterranean, Nelson was so deeply mortified that he made preparations for his return to England; and, as a ship could not be spared to convey him thither, he travelled through Germany to Hamburg, in company with Sir William and Lady Hamilton, and having embarked at Cuxhaven, landed at Yarmouth on the 6th of November 1800, after an absence of three years from his native country. He was welcomed in England with every mark of popular respect and admiration; in the towns through which he passed the people came out to meet him, and in London he was feasted by the city, drawn by the populace, thanked for his victory by the Common Council, and presented with a gold-hilted sword studded with diamonds. He had now every earthly blessing except domestic happiness, which, in consequence of his infatuated attachment to Lady Hamilton, he had forfeited for ever. Before he had been three months in England he separated from Lady Nelson, after much uneasiness and recrimination on both sides. On taking final leave of her, on 13th January 1801, he emphatically said "I call God to witness there is nothing in you or your conduct I wish otherwise." His best friends remonstrated against this causeless and cruel desertion; but their expostulations produced no other effect than to make him displeased with them, and dissatisfied with himself.

The three northern courts of Denmark, Sweden, and Russia, had now formed a confederacy for the purpose of setting limits to the naval pretensions of Great Britain; and as such a combination, under the influence of France, would soon have become formidable, the British cabinet instantly prepared to crush it. With this view a formidable fleet was fitted out for the North Seas, and the chief command of it given to Sir Hyde Parker; under whom Nelson, who had recently been made vice-admiral of the blue, consented to serve as second in command. The fleet sailed from Yarmouth on the 12th of March 1801; and on the 30th of the same month, Lord Nelson, having shifted his flag from the *St George* to the *Elephant*, led the way through the Sound, which was passed without any loss. The Danes had made every preparation for a determined resistance. Besides, the navigation was little known and extremely intricate; all the buoys had been removed; the channel was considered as impracticable for so large a fleet; and in a council of war, held on board of the flag-ship, considerable diversity of opinion prevailed. Nelson, however, cut short the discussion by offering his services for the attack, requiring only ten sail of the line and the whole of the smaller craft. Sir Hyde Parker assented, but gave him two more line-of-battle ships than he had asked, and left everything to his own judgment. On the morning of the 1st of April, the whole fleet moved to an anchorage within two leagues of the town; and about one o'clock Nelson, having completed his last examination of the ground, made the signal to weigh,

¹ In connection with this whole matter, the heaviest accusations have been again and again brought against Nelson. He has been accused of "treachery," in annulling the treaty of capitulation, and of "murder" in the execution of Francesco Caraccioli. The entire question has been subjected to a minute and careful examination by Sir N. Harris Nicolas, in an Appendix to the third volume of his edition of Nelson's *Dispatches*, where he endeavours to mitigate or remove the weighty charges brought against the brave admiral. The impression left upon the mind of the reader by the vast amount of evidence therein accumulated is, that while Nelson was possibly wrong in suspending the capitulation, even although its conditions were not executed, nevertheless, "the intentions and motives" (to use the words of Lord Spencer, then first lord of the Admiralty, and a statesman of great humanity of character, "by which all his measures were governed, were as pure and good as their success was complete." Nelson believed at the time that he acted correctly, and retained the same opinion to the end of his life. It must, however, continue to be deeply regretted that he should have seen it his duty to suspend the treaty, as often as the dark consequences are contemplated which ensued after the rebels were handed over to the Neapolitan authorities. With respect, again, to the execution of the old Neapolitan commodore, who commanded the republican gunboats, and fired upon the Neapolitan frigate, Sir Harris pronounces it as his deliberate opinion, in view of all the evidence of the case, that "it is indisputable that Caraccioli, and the other Neapolitans who fought against those forces, had, according to the law of every nation in Europe, committed high treason of a flagrant description, and that they were consequently rebels." The justice of the sentence was therefore unquestionable; and the question of humanity could only be fairly pronounced upon by those who know the entire circumstances in which Nelson was placed.

Nelson. which was received with a shout throughout the whole division destined for the attack. They weighed with a light and favourable wind, the small craft pointing out the course to be followed; and the whole division, having coasted along the shoal called the Middle Ground, doubled its farther extremity, and anchored there just as the darkness closed, the signal to prepare for action having been made early in the evening. As his anchor dropped, Nelson exclaimed, "I will fight them the moment I have a fair wind."

On the following morning, at half-past nine, the signal was made for the ships to weigh in succession; at ten minutes after ten the action commenced, at the distance of about half a cable length from the enemy; and by half-past eleven the battle became general. The plan of attack had been complete; but seldom had any project of the kind been disconcerted by more untoward accidents. Three of the ships had grounded, and only one gun-brig and two bomb-vessels could be got fairly into action. Nelson's agitation was extreme when he found himself, before the action began, deprived of a fourth part of his force; but no sooner was he in action than the wild music of the fight seemed to drive away all anxious thoughts; his countenance brightened, and his conversation became joyous, animated, and delightful. At one o'clock the enemy's fire continued unslackened; and the commander-in-chief, despairing of success, made the signal for discontinuing the action. At this moment, whilst Nelson was pacing the quarter-deck in all the excitement of battle, a shot passing through the main-mast, knocked the splinters about. "It is warm work," said he, "and this day may be the last to any of us at a moment; but, mark you," he added, "I would not be elsewhere for thousands." The signal-lieutenant now called out that the signal for discontinuing the action had been thrown out by the commander-in-chief. Nelson continued to walk the deck, and appeared not to notice it. At the next turn, the lieutenant asked if he should repeat the signal. "No," replied Nelson; "acknowledge it." He then called to know if the signal for close action was still hoisted; and being answered in the affirmative, said, "Mind you keep it so." A little after, "I have a right to be blind sometimes, Foley," added he, addressing the captain; then putting the glass to his blind eye, in a mood of sportive bitterness, which gives an inexpressible interest to the scene, "I really do not see the signal," he exclaimed; and after a pause, "Keep mine for closer battle flying; that's the way I answer such signals; nail mine to the mast."

Between one and two o'clock, however, the fire of the Danes slackened: by half-past two the action had ceased, except with the Crown batteries, and one or two ships which had renewed their fire, though with but little effect. At this critical moment, Nelson, with his accustomed presence of mind, resolved to secure the advantage he had gained, and to open a negotiation. He retired into the stern gallery, and wrote to the Crown Prince thus: "Vice-Admiral Lord Nelson has been commanded to spare Denmark when she no longer resists. The line of defence which covered her shores has struck to the British flag;—but if the firing is continued on the part of Denmark, he must set on fire all the prizes he has taken, without having the power of saving the men who have so nobly defended them. The brave Danes are the brothers, and should never be the enemies, of the English." This, after an interchange of communications, led to an interview between Nelson and the Crown Prince, at which the preliminaries of negotiations were adjusted; and a treaty was at length concluded, by which the northern confederacy was dissolved, and the maritime superiority of Britain unequivocally recognised. For the battle of Copenhagen, Nelson was raised to the rank of viscount, and, on the recall of Sir Hyde Parker, appointed to the chief command in the North Sea. His complaints in his correspondence (vol. iv. of *Dispatches and*

Letters) are loud and indignant, however, that the gallantry of his captains had not, as after other great battles, been rewarded with medals, and that the city of London had withheld its thanks from those who won that brilliant victory. "I long to have the medal for Copenhagen," he said, "which I would not give up to be made an English duke." But the medal never came.

Having settled affairs in the Baltic, Lord Nelson returned in a frigate to England. But he had not been many weeks ashore when he was called upon to attack the flotilla which had been prepared at Boulogne for the threatened invasion of England. The enemy were fully prepared, however, and though nothing could exceed the gallantry with which they were assailed, the enterprise proved unsuccessful. He now desired to be relieved from this boat-service, thinking it an unsuitable employment for a vice-admiral; and his wishes were speedily gratified by the signature of the preliminaries of peace.

He had purchased a house and an estate at Merton in Surrey, meaning to pass there the remainder of his days, in the society of Sir William and Lady Hamilton. But the happiness which he had promised himself was not of long continuance. Sir William Hamilton died early in 1803. A few weeks subsequent to this event the war was renewed; and the day after his Majesty's message to Parliament, announcing the recommencement of hostilities, Lord Nelson departed to assume the command of the fleet in the Mediterranean.

On the 20th of May 1803, he hoisted his flag on board the Victory, and having taken his station immediately off Toulon, he there waited with incessant watchfulness for the coming out of the enemy. This blockade proved one of the longest and most persevering that have been recorded in our naval annals; yet notwithstanding all his vigilance, the Toulon fleet put to sea on the 18th of January 1805, and shortly afterwards formed a junction with the Spanish squadron at Cadiz; Sir John Orde, who commanded off that port, having retired at their approach. Nelson had formed his own judgment of their destination, when Donald Campbell, then an admiral in the Portuguese service, went on board of the Victory, and communicated his certain knowledge that the combined French and Spanish fleets were bound for the West Indies. The enemy had five and thirty days' start; but Nelson calculated that he should gain eight or ten days by his exertions. To the West Indies therefore he bent all sail with his ten ships, in eager pursuit of eighteen, and on the 4th of June reached Barbadoes, whither he had sent despatches before him. Deceived by false intelligence, he then stood to the southward in quest of the enemy; but advices having met him by the way that the combined fleets were at Martinique, he immediately sailed for that island, where he arrived on the 9th, and received certain intelligence that they had passed to the leeward of Antigua the preceding day, and taken a homeward-bound convoy. It was now clear that the enemy, having accomplished the object of their cruise, were flying back to Europe; and accordingly, on the 13th, he steered for Europe in pursuit of them. On the 17th July he came in sight of Cape St Vincent, and directed his course towards Gibraltar, where he soon afterwards anchored, and went on shore for the first time since the 16th of June 1803. The combined fleet having thus eluded his pursuit, he returned almost inconsolable to England, to reinforce the Channel fleet with his squadron, lest the enemy should bear down upon Brest with their whole collected force.

Having landed at Portsmouth, Lord Nelson at length received news of the enemy's fleet. After an inconclusive action, in which they had run the gauntlet through Sir Robert Calder's squadron on the 22d of July, about 60 leagues west of Cape Finisterre, they had proceeded to Ferrol, brought out the squadron which there awaited their

Nelson. arrival, and with it entered Cadiz in safety. Upon receiving this intelligence, Nelson again offered his services, which were willingly accepted; and Lord Barham, then at the head of the Admiralty, gave him a list of the navy, desiring him to choose his own officers. No appointment could be more in unison with the feelings and judgment of the nation. The Victory, destined once more to bear his flag, was refitted with incredible despatch; and such was his impatience to be at the scene of action, that although the wind proved adverse, he worked down the Channel, and, after a rough passage, arrived off Cadiz on the 29th of September, the day on which the French admiral, Villeneuve, had received peremptory orders to put to sea the very first opportunity. Fearing that the enemy, if they knew his force, might be deterred from venturing to sea, he kept out of sight of land; desired Collingwood to hoist no colours, and fire no salute; and wrote to Gibraltar to request that the force of the fleet might not be inserted in the gazette published there. The station which he chose was some 50 or 60 miles to the westward of Cadiz, off Cape St Mary's.

On the 9th of October Lord Nelson communicated to Admiral Collingwood his plan of attack. The order of sailing was to be the order of battle. His object he declared to be close and decisive action. "In case signals cannot be seen or clearly understood," said he, "no captain can do wrong if he place his ship alongside that of an enemy." This was what he called the *Nelson-touch*. It was a mode of attack equally new and simple. Every one comprehended it in a moment, and was convinced that it would succeed. In fact, it proved irresistible.

Villeneuve, relying upon the information he had received, put to sea on the 19th, and at daybreak, on the 21st of October 1805, the combined fleets were distinctly seen from the deck of the Victory, formed in a close line ahead, about 12 miles to the leeward, and standing to the southward, off Cape Trafalgar. The British fleet consisted of 27 sail of the line and 4 frigates; the enemy's fleet of 33 sail of the line and 7 frigates. But their superiority was greater in size and in weight of metal than in numbers; they had 4000 troops on board; and the best riflemen who could be procured, many of them Tyrolese, were dispersed throughout the ships. Soon after daylight Nelson came on deck, and the signal was made to bear down on the enemy in two lines, upon which the fleet set all sail; Collingwood, in the Royal Sovereign, leading the lee line of 13 ships, and Nelson, in the Victory, leading the weather line of 14. Having seen that all was right, he retired to his cabin, and wrote a devout prayer, in which, after beseeching the Almighty to grant a great and glorious victory, he committed his life to the God of Battles; and in another writing which he annexed in the same diary, he bequeathed Lady Hamilton as a legacy to his king and country, and commended to the public beneficence his adopted daughter, Horatia, desiring that in future she would use the name of Nelson only. Blackwood went on board the Victory about six, and found him in good spirits, but very calm, and with none of that exhilaration which he had displayed on entering into battle at Aboukir and at Copenhagen. With a prophetic anticipation, he seems to have looked for death with almost as certain a conviction as for victory. His whole attention was fixed upon the enemy, who now formed their line with much skill on the larboard tack. Then appeared that signal—Nelson's last signal—which will be remembered as long as the language or even the memory of England shall endure:—"England expects every man to do his duty." It was received throughout the fleet with a responsive burst of acclamation, rendered sublime by the spirit which it breathed, and the determination it expressed. "Now," said Nelson, "I can do no more. We must trust to the great disposer of all events, and the justice of our cause. I thank God for this great opportunity of doing my duty."

On this memorable day Nelson wore, as usual, his admiral's frock-coat, bearing upon the left breast the various orders with which he had at different times been invested. Decorations which rendered him so conspicuous a mark to the enemy were beheld with ominous apprehension by his officers, especially as it was known that there were riflemen on board the French ships, and it could not be doubted that his life would be particularly aimed at. This was a point, however, on which it was hopeless to reason or remonstrate with him. "In honour I gained them," said he, when allusion was made to the insignia he wore, "and in honour I will die with them." Nevertheless, Captain Blackwood, and his own captain, Hardy, having represented to him how advantageous it would be to the fleet were he to keep out of action as long as possible, he consented that the Temeraire and the Levathan, which were sailing abreast of the Victory should be ordered to pass ahead. But the order was unavailing; for these ships could not pass ahead if the Victory continued to carry all her sail; yet, so far from shortening sail, Nelson took an evident pleasure in pressing on, and rendering it impossible for them to obey his own order. As the enemy showed no colours till late in the action, the Santissima Trinidad was distinguishable only by her four decks; and to the bow of his old opponent in the action off Cape St Vincent he ordered the Victory to be steered. In the meantime, an incessant raking fire was kept up on the Victory; and as the ship approached, Nelson remarked, "This is too warm work to last long." She had not yet returned a single gun, though by this time fifty of her men had been killed or wounded, and her main-top-mast, with all her standing-sails and booms, shot away. A few minutes after 12, however, she opened her fire from both sides of her deck, and soon afterwards ran on board the Redoubtable, just as her tiller ropes were shot away. Captain Harvey, in the Temeraire, fell on board the Redoubtable on the other side; and another enemy's ship, the *Pougueux*, fell on board the Temeraire; so that these four ships formed as compact a tier as if they had been moored together, their heads lying all the same way. The lieutenants of the Victory now depressed their guns, and fired with a diminished charge, lest the shot should pass through and injure the Temeraire; and as there was danger that the Redoubtable might take fire from the lower-deck guns, the muzzles of which, when run out, touched her sides, the fireman of each gun stood ready with a bucket of water, which, as soon as the gun had been discharged, he dashed into the hole made by the shot. In this situation, the Victory kept up an incessant fire from both sides, directing her larboard guns on the *Bucentaur* and *Santissima Trinidad*.

But Nelson's hour was now come. It had been part of his prayer that the British fleet might be as distinguished for humanity in victory as for bravery in battle. Setting an example himself, he twice gave orders to cease firing upon the Redoubtable, supposing she had struck, because her great guns were silent; for as she carried no flag, it was impossible instantly to ascertain the fact. From the ship which he had thus twice spared he received his death-wound. In the heat of the action, about a quarter after one o'clock, a musket-ball from the mizen-top of the Redoubtable struck the epaulette on his left shoulder; and he fell upon his face on the spot covered with the blood of his secretary, Mr Scott, who had been killed a short time before. "They have done for me at last, Hardy," said he, as a serjeant of marines and two seamen raised him from the deck. "I hope not," replied Captain Hardy. "Yes," he rejoined; "my back bone is shot through." But, though mortally wounded, he did not for a moment lose that presence of mind for which he was ever distinguished. As they were carrying him down the ladder to the cockpit, he observed that the tiller ropes, which had been shot away

Nelson.

Nelson: early in the action, were not yet replaced, and ordered that new ones should be immediately rove. He was laid upon a pallet in the midshipman's berth, and the surgeon being called, it was soon perceived that the wound he had received would speedily prove mortal; but this was concealed from all except Captain Hardy, the chaplain, and the medical attendants. Being certain, however, from the sensation which he felt in his back, and the gush of blood within his breast, that no human aid could avail him, he insisted that the surgeon should leave him, and attend to those to whom he might be useful. "You can do nothing for me," said he. Suffering from intense thirst, and in great pain, he expressed much anxiety as to the fate of the action; and his countenance brightened with a gleam of joy as often as the hurrah of the crew of the Victory announced that an enemy's ship had struck.

At length he became very impatient to see Captain Hardy, whom he repeatedly sent for; but that officer could not leave the deck, and upwards of an hour elapsed before he could quit his station. When they met, they shook hands in silence, Hardy struggling to suppress his emotions. "Well, Hardy," said Nelson, "how goes the day with us?" "Very well," replied the captain; "ten ships have struck, but five of the enemy's van have tacked, and show an intention of bearing down on the Victory. I have called two or three of our fresh ships round, and have no doubt of giving them a drubbing." "I hope," said Nelson, "none of our ships have struck." "There is no fear of that," answered Hardy; upon which the dying hero said, "I am a dead man: I am going fast; it will soon be all over with me; my back is shot through." Hardy, unable any longer to suppress his feelings, hastened upon deck; but in some fifty minutes, returned, and taking the hand of his dying commander, congratulated him on having gained a complete victory. He did not know how many of the enemy had struck, as it was impossible to perceive them distinctly; but fourteen or fifteen at least had surrendered. "That's well," answered Nelson; "but I had bargained for twenty." Then, in a stronger voice, he said, "Anchor, Hardy, anchor;" and again, most earnestly, "Do you anchor." Next to his country, Lady Hamilton occupied his thoughts. "Take care of my dear Lady Hamilton, Hardy; take care of poor Lady Hamilton;" and, a few minutes before he expired, he said to the chaplain, "Remember that I leave Lady Hamilton and my daughter Horatia as a legacy to my country." The last words he was heard to utter distinctly were, "I thank God, I have done my duty." He expired at half-past four o'clock, three hours and a quarter after he had received his fatal wound.

The total loss of the British in the battle of Trafalgar amounted to 1587. Twenty of the enemy struck, and of the ships which escaped, four were afterwards taken by Sir Richard Strahan. But unhappily the fleet did not anchor, as Lord Nelson with his dying breath had enjoined; a heavy gale came on from the S.W.; some of the prizes went down, some were driven on the shore, one effected its escape into Cadiz, others were destroyed, and four only were, by the greatest exertions, saved. Still, by this mighty

achievement, the navies of France and Spain received a blow from which they were not destined soon to recover; the gigantic combinations of Napoleon, with a view to a descent upon England, were completely baffled; and the success of his campaign of Austerlitz was in a great measure neutralized. The remains of Lord Nelson were buried at St Paul's, on the 9th of January 1806. It is needless to add, that all the honours which a grateful country could bestow were heaped on the memory of the man who had achieved this unequalled victory.¹

In Lord Nelson's professional character were united all the highest qualities of a great commander,—wonderful foresight, prompt judgment, never-failing presence of mind, ardent zeal, unbounded confidence in the resources of his own mind, and that intuitive decision in the midst of difficulty and peril which is the distinguishing attribute of great military or naval genius. His daring was without rashness, and his enterprise founded upon the most skilful calculation; his ardour never outran his understanding, nor his love of glory a due consideration of the material and moral means by which alone success can be obtained. His talents for command were of the highest order, and he knew the invaluable secret of inspiring other men with confidence in him, as well as with confidence in themselves. But the best character which can be drawn of him is the history of his achievements, all stamped with the impression of his genius; and, that nothing might be wanting to the consummation of his renown, he departed in a bright blaze of glory, leaving to his country a name which is her pride and boast, and an example which will continue to be her shield and her strength. (See, in particular, the *Dispatches and Letters of Vice-Admiral Lord Viscount Nelson*, by Sir Nicholas Harris Nicolas, 7 vols., Lond. 1844-46; also Southey's *Life of Nelson*, in 2 vols. 12mo; Life by Clarke and M'Arthur, 8vo; Ekins' *Naval History*, 4to; and James's *Naval History*, 6 vols. 8vo.) (J. B.—E.)

NELSON, *Robert*, the author of several works on practical religion, was the son of a wealthy London merchant, and was born in 1656. After attending St Paul's School, he studied at Cambridge as a fellow-commoner of Trinity College. On his entrance into active life, his worth and accomplishments raised him to a high place in the estimation of the learned. He became the bosom-friend of Tillotson; and in 1680 was elected a fellow of the Royal Society. But not until 1691, at the conclusion of a series of visits to the Continent, did his character as an earnest friend of religion and philanthropy begin to appear in its full excellence. He became a liberal patron of charity-schools; and there was not a scheme for propagating religion, either at home or abroad, to which he did not afford substantial encouragement; while at the same time his pen was perseveringly employed in advocating practical religion. It was while engaged in performing the pious task of writing the life of his old tutor, Bishop Bull, that he contracted his last illness. His death took place in 1715. Nelson's best-known works are,—*A Companion for the Festivals and Fasts of the Church of England*, 8vo, 1704; *The Great Duty of Frequenting the Christian Sacrifice*, 8vo, 1707;

**Nelson,
Robert.**

¹ Lord Nelson's brother, the Rev. William Nelson, D.D., was created Earl Nelson of Trafalgar and of Merton on the 20th November 1805, with an annual grant of L.6000, and with permission from his Majesty to inherit his deceased brother's Sicilian dukedom of Bronté. Besides L.100,000 for the purchase of an estate, L.10,000 were voted to each of the hero's sisters. His dying request in behalf of Lady Hamilton and his "adopted daughter Horatia Nelson Thompson," the British nation saw fit to utterly disregard. The one he left, in a codicil to his will, written a few hours before his fall, "a legacy to my king and country;" and the other "to the beneficence of my country." "These," continues the document, "are the only favours I ask of my king and country at this moment, when I am going to fight their battle;" yet it appears from Pettigrew's *Memoirs of Nelson*, vol. ii., that this codicil was virtuously concealed by the hero's reverend brother until the parliamentary grant to himself was duly completed. The subsequent years of the unfortunate Lady Hamilton's life one had rather pass over. She died at Calais in extreme poverty and great distress on the 6th January 1814. Nelson's daughter, Horatia,—respecting whose maternal extraction Sir N. H. Nicolas has diligently collected so much unsatisfactory information (Nelson's *Dispatches*, &c., vol. vii., pp. 369-396), in his attempt to remove the generally received and most obvious opinion on the point,—was married in February 1822 to the Rev. Philip Ward, an English clergyman. Some endeavour has recently been made, it seems, to assist her children in entering upon life, with the design, probably, of atoning in some measure for the neglect shown to the dying request of the hero of Trafalgar.

anus.

The Practice of True Devotion, 8vo, 1708; and *The Whole Duty of a Christian*, 8vo, 1718. They have all passed through several editions.

NEMAUSUS (the modern *Nîmes*), a city of Gallia Narbonensis, was the capital of the Volcæ Arecomici, and was situated on the road between Italy and Iberia. As early as the reign of Augustus it was a *colonia*; and in the days of Strabo it possessed the *Jus Latii*; and was on that account independent of the Roman governors. The territory of Nemausus comprised twenty-four populous villages. Its most notable product was cheese, which was exported to Rome. There are still remaining many striking monuments of the splendour of the ancient city of Nemausus. The principal of these are a spacious amphitheatre, a temple called the *Maison Carée*, a structure known as the *Tour Magne*, and the famous Roman aqueduct, named the *Pont du Gard*. (See NIMES.)

NEMEAN GAMES, THE, constituted one of the four great national festivals of the Greeks. The ordinary account of their institution is the legend that follows. As Hypsipyle, the nurse of Opheltes or Archemorus, the infant son of Lycurgus and Eurydice, was sauntering one day with her young charge through the valley of Nemea, near the city of Cleonæ, she met the seven champions on their way to attack Thebes. They asked her to conduct them to the nearest fountain, where they might slake their thirst. She left her child lying on the ground, and hastened away to comply with their request. On her return, she found that Opheltes had been devoured by a dragon. The seven champions, after destroying the monster, celebrated funeral games in honour of the child. These games falling into disuse, were revived by Hercules after he had slain the Nemean lion, and were then for the first time consecrated to Jupiter. They derived their name from the grove Nemea, in which they were held. There a temple, a theatre, and a stadium were in course of time erected; and thither, twice every Olympiad, in summer and winter alternately, athletes of every kind, and even musicians, were wont to flock from all parts of Greece. The judges were chosen by turns from Cleonæ, Corinth, and Argos, and, in commemoration of the funereal origin of the festival, they were arrayed in sable garments. A chaplet, formed of olive branches, and afterwards of green parsley, was the reward of the victors. The last time at which the celebration of the Nemean games is mentioned in history is in the reign of Hadrian. They seem to have been finally discontinued shortly afterwards. The ruined temple of Jupiter Nemesius still indicates the scene of this great biennial festival.

NEMESIANUS, MARCUS AURELIUS OLYMPIUS, a Latin bucolic poet, flourished at the court of the Emperor Carus towards the close of the third century, and is supposed, from the epithet "Carthaginiensis" generally attached to his name, to have been a native of Africa. In the poetical contests of that day he owned no superior except the young prince Numerianus. "He shone out," says Vopiscus, "adorned with all the crowns of victory." His bucolic poems were three; and under the several names of *Cynagetica*, *Halieutica*, and *Nautica*, treated of hunting, fishing, and aquatics. A fragment of the first of these, amounting to 325 hexameter verses, is the only authenticated production of Nemesianus that is extant. It contains instructions for the rearing of dogs and horses, and the forming of nets and other hunting apparatus. The best edition is that of Stern, 8vo, Halle, 1832.

Wernsdorf, in his *Latinae Poetae Minores*, argues, on grounds somewhat plausible, that the piece entitled *Laudes Herculis*, usually printed among the works of Claudian, belongs to Nemesianus. Four of the eclogues generally ascribed to T. Calpurnius Siculus are sometimes erroneously attributed to the same author.

NEMESIS is generally represented in Grecian mythology as the daughter of Night. The ideas regarding her character seem to have been gradually developed. In the days of Hesiod she was regarded as the impersonation of the upbraiding of conscience, of the natural dread of punishment that springs up in the human heart after a sin has been committed. But as the feeling of remorse may be considered the vengeance of the offended moral law, Nemesis came to be held, especially among the tragic poets, as the goddess of retribution, relentlessly pursuing the guilty until she has driven them into irretrievable woe and ruin. In performing this function, however, she often suddenly cast the minions of fortune from the summits of prosperity down into the lowest depths of misery. By this circumstance a new phase of her character was developed. She came to be regarded as the personification of that supposed divine jealousy that is kindled at the sight of great human felicity, never rests until it has brought a serenely happy life to a gloomy and tragical close, and thus acts as the impartial distributor of happiness and unhappiness among the sons of men. Nemesis had several surnames. She was called *Rhamnusia* or *Rhamnysis*, from Rhamnus, a town of Attica, where she was worshipped; and *Adrasteia*, from Adrastus, King of Argos, who first built a temple to her on the River Asopus (*Asopo*). The ancients generally represented Nemesis as a crowned virgin, majestic in her bearing, and closely resembling Venus in the grace of her person and the beauty of her countenance, with a whip in one hand and a pair of scales in the other.

NEMESIUS, one of the ablest of the ancient Christian philosophers, and the author of a Greek treatise *On the Nature of Man*, flourished, as bishop of Emesa in Syria, probably about the end of the fourth century. His book is the only record that remains of his existence. It seems to be little else than a synopsis of the orthodox philosophy of that day, written in a style generally clear, easy, and elegant. Man is considered as a complex being, composed of a body and a soul. It is while discussing the former of these divisions that Nemesius displays his learning and his power of theorizing to the best advantage. His remarks on the spleen, the nerves, the glands, and other organs of the body, prove him to have been a thorough adept in all the physiological lore of that age; and his curious speculations touching the motion of the pulse, and the use of the bile, have led Fell, Brucker, and others of his indiscriminate admirers, to suppose that he was acquainted with the circulation of the blood and the functions of the liver; an opinion, however, which Freind, in his *History of Physic*, and Haller, in his *Bibliotheca Anatomica*, contest. Treating of the other great division of his subject, Nemesius considers the soul as composed of two parts, the rational part consisting of thought, memory, and especially will, and the irrational part consisting of the desires and the passions. On the liberty of the human will, and other kindred subjects, his views are just and profound. He holds, however, the Platonic doctrine of the pre-existence of the soul.

An edition of the work of Nemesius in the original was given to the world by Nicasius Ellebodium, 8vo, Antwerp, 1565; and by Fell, 8vo, Oxford, 1671. The latest and the best edition is that of F. Matthæi, 8vo, Halle, 1802. It was translated into English by George Wither, 12mo, London, 1636; into German by Osterhammer, 8vo, Salzburg, 1819; and into French by J. B. Thibault, 8vo, Paris, 1844.

NEMOURS, a town of France, department of Seine-et-Marne, on the Loing, nearly surrounded by that river and by the canal which joins the Seine and Loire, 10 miles S. of Fontainebleau. It is well built, and has broad streets. The old castle, formerly the residence of the dukes of Nemours, contains a public library and several other establishments. There is a handsome parish church, an hospital, and a theatre. Leather, beer, vinegar, marble, earthenware,

mus.

&c., are manufactured here; and an active trade is carried on in the produce of the country. Pop. 3782.

NENAGH, a town of Ireland, province of Munster, and county of Tipperary, occupies a beautiful situation on a hill near the River Nenagh, 23 miles N.E. of Limerick, and 82 miles W.S.W. of Dublin. It is well built, and contains one principal street, which is crossed at right angles by four others. There is an Episcopal, a Roman Catholic, a Methodist, and an Independent church; several schools; a fever hospital; dispensary; and barracks. Nenagh has also an ancient castle of Norman architecture, and the remains of a Franciscan monastery. Woollen cloth, tobacco, soap, and candles, are manufactured here; and a considerable trade is carried on in corn, cattle, bacon, butter, and eggs. Several fairs are held yearly here. Pop. 9292.

NENE, or NEN, a river of England, Northamptonshire, is formed by two branches, one from the north, rising at Naseby, and the other from the west, rising near Staverton, a village S.W. of Daventry. These streams unite at Northampton, and thence the river flows towards the N.E. through a beautiful valley, and falls into the Wash. The Nene receives many tributaries, though of small size, from the left; but none from the right, as the hills present a steep side to it, and send their streams to the Ouse. Northampton and Peterborough are the principal towns on its course.

NENNIUS, the reputed author of an ancient history of the Britons, entitled *Historia Britonum*, is said to have been abbot of Bangor at the beginning of the seventh century. The book which is ascribed to him commences with a fabulous account of the colonization of the island, and brings the narrative down to the year 655. Its chronological blunders, and the many other proofs of its want of authenticity, render it a very unsafe historical authority. It is chiefly valuable on account of its containing those stories of King Arthur, Merlin, and other legendary heroes, which became such favourite themes among the authors of succeeding ages. The latest editions of the *Historia Britonum* are those by the Rev. W. Gunn, B.D., 8vo, London, 1819; and Mr Joseph Stevenson, 8vo, London, 1838. (Wright's *Biographia Britannica Literaria*.)

NEOPHYTES, a name given by the ancient Christians to those heathens who had newly embraced the faith; such persons being considered as regenerated, or born anew. The term *neophytes* has also been used for new priests, or those just admitted into orders; and sometimes for the novices in monasteries or convents. It is still applied by Roman Catholic missionaries to converts made among the heathen.

NEO-PLATONISTS. See ALEXANDRIAN SCHOOL.

NEOPTOLEMUS, the son of Achilles and Deidameia, daughter of Lycomedes, King of the Dolopians, was born shortly before the Trojan war. When it was prophesied, towards the close of the siege of Troy, that the city could not be taken without the son of Achilles, Ulysses and Diomedes were despatched to bring the young man, and found him in the house of his maternal grandfather, in the island of Scyros. He was then called Pyrrhus, on account of his fair hair; but after his arrival at the scene of war, he was generally known by the name of Neoptolemus, i.e., "the young warrior." The son of Achilles soon proved himself worthy of his brave, savage, and vindictive father. On the night of the sacking of Troy his deeds were bold and atrocious beyond those of all the other Greeks; and it was his sword that was most fatal to the royal house of Priam. He was among the foremost to leap from the wooden horse upon the devoted and unsuspecting city: he dashed down the little Astyanax, the child of Hector, from the top of a tower; he sacrificed the Princess Polyxena upon the tomb of Achilles; and he slew Priam and Polites, father and son, together, at the altar of Jupiter, before the eyes of Queen Hecuba and her daughters. On the distribution of the

captives, Andromache, the widow of Hector, fell to his lot, and became his wife. After this date the various accounts of the life of Neoptolemus are very contradictory. According to some authors, he returned to his hereditary kingdom of Phthia; while, according to others, he fixed his abode permanently at Epirus. It is generally agreed, however, that Menelaus and Helen bestowed upon him the hand of their daughter Hermione. Shortly after this he was slain, during a visit to Delphi, by some vindictive foe, about whom ancient writers are not agreed. His remains were interred within the temple; and long afterwards, when the Gauls attacked the city, his spirit rose, it is said, to defend the sacred place.

NEOTS, St, a market-town of England, Huntingdonshire, stands on the right bank of the Ouse, 9 miles S.W. of Huntingdon, and 56 N. by W. of London. It has several well built streets, and a market-place; but from the lowness of its situation, the town is exposed to the danger of being flooded by the river. The church of St Neot's, which is considered the finest in the county, is in the perpendicular English style, and has a handsome tower 150 feet high. There are other churches in the town, belonging to the Baptists and Methodists, and several schools. The Ouse is here crossed by a bridge of eleven arches, six of which are on the low ground near the river. The principal manufacture in St Neot's is paper, which gives employment to many of the inhabitants. A large retail trade is carried on. Pop. (1851) 2951.

NEPAUL, or NIPAL, an extensive country of Hindustan, long and narrow in its form, and, although somewhat curtailed in its dimensions by the progress of British conquest, still one of the largest and most compact independent kingdoms in the country. To the N. it is bounded by the great mountain-wall of the Himalayas, which separates it from Thibet; to the S. the Nepaul territory reaches about 20 miles beyond the base of the mountains into the plains, being bounded by the provinces of Purneah, Tirhoot, Sarun, and Goruckpore; to the E. by the British territory of Darjeeling and the native principality of Sikkim, which extends to the Chinese frontier. The kingdom of Oude, the territories of which have been recently annexed to the British dominions, forms the boundary on the S.W. Previously to the war with Britain in 1814-16, the conquests of the Ghoorkhas or Nepaulese extended to the banks of the Sutlege, the eastern river of the Punjab; but the boundary is now the River Cali, or the western branch of the Goggra, which separates the Ghoorkha territory from the British province of Kumaon. The above limits, however, include a territory much larger than that to which the peculiar name of Nepaul proper belongs, and made up of conquests gained by the Ghoorkhas within the last eighty years from a variety of petty hill states. This extended dominion is mostly included between the twenty-seventh and thirty-first degrees of N. latitude, and in extreme length may be estimated at 460 miles, by 150 miles in breadth. The following are the modern districts into which this territory is divided:—

- | | |
|------------------------------|----------------|
| 1. Nepaul proper. | 6. Khatang. |
| 2. Country of the 24 rajahs. | 7. Chayenpoor. |
| 3. Country of the 22 rajahs. | 8. Saptari. |
| 4. Muckwanpoor. | 9. Morung. |
| 5. Kirauts. | |

Nepaul is extremely diversified in its surface. Among its lofty summits is Mount Everest, the highest peak in the world (29,002 feet), while the whole range which forms its northern boundary rises to the level of perpetual snow. These high mountains generally decline into lower hills, from which they are separated by fine valleys, still considerably above the level of the plains, and the lowest belt of the Nepaul dominions forms part of the great plain of Hindustan. Immediately to the N. of this flat country there is a region of nearly the same width, consisting of small hills, which rise gra-

||
Nepaul.

Nepaul.

dually towards the north, and are watered by many streams from the loftier mountains to which these hills gradually unite. The hills are covered with forests: on the lower hills are found the saul forests, which, with the pines, are not surpassed in any country, either for straightness or size, as well as for strength and durability. Higher up there is a variety of other trees, and amongst the northern hills many pines, and an abundance of mimosa, from which the catechu of India is obtained; also oaks, walnut and chestnut trees, hornbeam, Weymouth pine, and common spruce, for the most part of but very little value, owing to the inaccessible nature of the country. The breadth of this mountainous belt immediately north and east of Catmandoo is estimated at from thirty to forty miles. This is a very elevated region, consisting of one mountain heaped upon another rising to a great height, so that in winter their summits are for a short time covered with snow, and it even falls sometimes in the valley below. A hoar frost also very often covers the ground; but although the cold is occasionally for three or four months severe enough to freeze the tanks and pools of standing water, the rivers are never frozen. Between the mountains are narrow valleys of from 3000 to 6000 feet above the plains of Bengal. The height of the valley of Nepaul, measured by the barometer, is about 4000 feet. It is nearly of an oval figure; its greatest extent from north to south is twelve miles, and it stretches east and west nine miles; and though it scarcely lies in a higher latitude than twenty-seven and a half degrees, yet it enjoys nearly the same climate as the southern countries of Europe.

Climate.

Lying near a region buried in snow, its climate must no doubt be somewhat modified by such a vicinity. Still Kirkpatrick mentions, that in summer the thermometer rose once to eighty-seven degrees during his residence in the valley; and its usual height about noon varied from eighty-one to eighty-four degrees. At sun-rise it was commonly between fifty and fifty-four, and at nine in the evening it generally fluctuated from sixty-two to sixty-six degrees. Fifty-one observations, from the 17th to the 25th March, gave an average of sixty-seven degrees. The seasons are nearly the same with those in Upper Hindustan. The rains commence a little earlier, and set in from the south-east quarter; they continue for days without intermission, and are generally very violent. The mountain-torrents rush down in consequence with great impetuosity, overflowing their banks, and spreading over all the adjacent country. By these violent inundations, the plain is cut into numerous and deep ravines. The temperature varies necessarily with the elevation of the ground; so that by ascending the adjacent mountains, the heat of Bengal may in the course of a few days be exchanged for the cold of Russia.

Produce.

The produce also varies along with the climate. In some parts rattans and bamboos, both of enormous dimensions, are seen, and others produce only oaks and pines. In several parts the pine-apple and sugar-cane ripen, whilst others yield only barley, millet, and similar grains. The mulberry grows luxuriantly all over the hills; and they cut its young and tender shoots annually, whilst full of leaves, and, having dried them, stack them for fodder, which is said to be both nutritious and agreeable to the animals. In this comparatively cold and elevated climate, the periodical rains are not favourable for the ripening of fruits, which everywhere abound, but never come to perfection, the heat of the climate not being sufficient to bring them to maturity before the approach of the rains. Peaches grow wild on every hill; but one side of them is rotted by the damp, whilst the other side is green; and the grapes, which grow without shelter from the rains, are always bad. Kirkpatrick, however, from the spontaneous productions which he saw on the spot, namely, the peach, the raspberry, the walnut, the mulberry, and others, thought that all the fruits and esculent vegetables

of England might with proper attention be successfully raised in the mountainous valleys of Nepaul. In the warmer valleys, the pine-apple is uncommonly fine; as also the orange, which ripens in winter. The abundant rains, if they spoil the fruits, are, however, very favourable to the produce of grain; and wherever the land can be levelled into terraces, however narrow, it is well adapted for transplanted rice, which ripens after the rains have ceased. The least rocky faces of the hills are generally cut into these terraces, which are seen everywhere rising above each other. This operation produces numerous strips of level ground, more or less narrow, according to the steepness of the hills. Great labour and care are bestowed upon this operation, and it is often necessary to build a retaining wall to support the edge of the small strip of ground. Much attention is also paid to the levelling of its surface, to fit it for irrigation, as every rivulet is first conducted by drains to the higher cultivated spots, and then, after saturating them, to the lower range of fields. In some parts the same land gives a winter crop of wheat and barley. Where the land is too steep for terraces, it is generally cultivated after fallow with the hoe, and produces rice sown broadcast, maize, cotton, three kinds of pulse, a kind of mustard, manjeet or Indian madder, wheat, barley, and sugarcane. Tobacco is an article of general cultivation in these hills, and it is considered as of a fine quality. It is exported in considerable quantities both to the plains and to Bootan. One of the great staples of agriculture in these mountainous countries is a large species of cardamom; and ginger is likewise a valuable production in the country between Nepaul Proper and the Cali, though rice is still the main dependence of the farmer. Various dry rices are cultivated in Nepaul, under the general name of ghyra, some of which, so far from needing hot weather to bring them to maturity, are actually raised in situations very much exposed to falls of snow; whilst others do not require, as in Bengal, to be flooded, but flourish in the driest and loftiest spots. There are also amongst the spontaneous productions of this fertile soil several edible roots and herbs, which form a considerable part of the sustenance of the poorer inhabitants. Of these there are a species of yam, and a kind of wild asparagus, as well as various other plants well deserving the attention of travellers. There are also medicinal plants, and a rich variety of dyeing drugs procured from bitter or aromatic woods, which grow naturally in the country, and which are held in great estimation. The jeca is a very curious plant, from the expressed leaves of which is produced a juice called cheris, which is a potent narcotic, and possesses very valuable qualities, burning with a flame as bright as that of the purest resin. Its leaves are fabricated into a species of hemp, from which the Newars manufacture some coarse linen, and likewise a very strong kind of sackcloth. Though the soil seems well adapted to the growth of kitchen vegetables, yet the inhabitants are either too indolent or too unskilful to raise them. The only kitchen vegetables which Colonel Kirkpatrick met with were cabbages and pease of the worst kind. They have the Thibet turnip, but cannot raise it, any more than the potato, without renewing the seed annually. Amongst these mountains are found the common nettle and a plant resembling wormwood; also a curious shrub called khaksi, the leaf of which answers the purpose of emery or sandpaper, giving a fine polish to the harder woods.

The mountain pasture, though not so good as that in the low country, yet supports numerous flocks of sheep, which migrate with the seasons, in winter to the lower valleys, and in summer to the alpine regions, where they feed upon the herbage of those extensive tracts which lie in the neighbourhood of perpetual snow. The sheep in these altitudes are of considerable size, and have fine wool; the larger are the same as in the lower countries, but are not numerous.

Nepaul.

Buffaloes are not reared by the natives, neither are hogs nor goats, though the country is admirably adapted for both. Horses are brought from Thibet and from Kattywar, Sindh, and Guzerat; also the large ox of Thibet, or the *Bos grunniens*, described by Turner, the beautiful tail of which forms one of the exports from Nepaul; and the goat which produces the shawl wool. The kustoora or musk-deer is a native of Lower Thibet, though it is not very abundant anywhere. It is usually caught by means of a snare made of a particular kind of mountain bamboo. It is difficult to obtain the musk pure, even at Catmandoo; and Colonel Kirkpatrick mentions, that it is even usual to adulterate it whilst it is yet in the bag on the body of the animal. In the great forest which skirts the Nepaul territories throughout their whole extent, from Serinagur to the Teesta, wild animals abound. Elephants are found here in great numbers, and are a source of revenue to the Nepaul government. About 200 or 300 of these animals are caught annually; but most of them being very young, and not being above seven feet and a half in height, they are not of great value. They are extremely mischievous, and two or three of them sometimes take possession of the road, and obstruct the progress of travellers for a considerable time. A large herd of them assaulted the camp of the Nepaul deputies when they were on their way to Patna, and were with great difficulty driven away. They sometimes issue from the forest in droves, and overrun the cultivated country on its borders, penetrating sometimes a considerable space within the company's territories. The rhinoceros, the tiger, the leopard, and other ferocious animals, find shelter in the depths of the forests. The animal known in Bengal by the name of the Nepaul dog is brought from Upper and Lower Thibet, of which it is a native. It is a fierce, surly creature, about the size of an English bull-dog, and covered with thick long hair. Several very fine birds are found in these mountainous countries, as the manal (*Meleagris satyra*), and the damphyia (*Phasianus impeyanus*). They are a species of pheasants, the damphyia being of the golden, and the manal or moonal of the spotted sort. They are both extremely beautiful birds. The chakoor is well known to the Europeans of India under the name of the fire-eater. It is a species of partridge, and derives its name from its reputed power of swallowing fire. The fact is, that in the breeding season this bird is remarkably fond of red pepper, after eating two or three capsules of which, it will bite at a red coal if presented to it. The khalede is met with in the thickets which overrun the gorges of the mountains near Noakote. The sarus, wild goose, wild duck, and several others of the feathered species common to Bengal and the rest of the countries to the southward of Nepaul, are occasionally seen in this and the adjacent valleys; where, however, they merely appear as birds of passage, making Nepaul only a stage in their flight from Hindustan to Thibet.

Minerals.

The stones and ores collected in the country indicate the existence of a variety of minerals in the mountains of Nepaul, such as iron, lead, copper, &c. It was formerly a prevalent idea amongst the Hindus, from whom it was received by the British, that the country contained mines of gold. The only foundation for this notion appears to be, that in the course of commerce the gold of Thibet passed into Bengal and Bahar through Nepaul; or that a few grains of gold were occasionally collected in the sands of the rivers, or found in the consecrated pebbles of Gunduck; or sometimes that specimens of gold ore have been sent to the governor-general by way of presents or curiosities. Other accounts of gold mines may also be referred to the circumstance of scanty particles of gold being found in the beds of torrents from the mountains. With regard to silver, it is said that some veins of it have been discovered to the westward of Noakote. But Kirkpatrick, in

Nepaul.

his account of Nepaul, suspects that it has no better foundation than that silver has lately been found in certain ores which were very rich in lead; whilst others appeared to be a species of galena, well worth the working for the sake of the silver which they contained. Several attempts had been made to extract the silver, but by such an unskilful process, that most part of the baser metal was sacrificed, in consequence of which the return scarcely repaid the expense. The copper is found quite near the surface of the earth, the ore being dug from trenches open above, so that the work is entirely interrupted by the rainy season. Those ores are found in several varieties, and are said to be rich and of an excellent kind. The mine is shared amongst certain families along with the rajah, who, there is every reason to believe, claims the lion's share, and, as in all other parts of Hindustan, leaves the workmen a bare subsistence. Oude was formerly supplied with copper from Nepaul; but of late years it has been superseded by European copper, owing to the difficulties and expense of transferring it to the market through a mountainous country without navigable rivers. The iron ore is also found near the surface, and is not surpassed in excellence by that of any other country. Sulphur is likewise abundant, and procured in great quantities. There is no good authority for believing that either the ores of antimony or mercury are found in the territories of Nepaul; but the western parts abound in arsenic and pyrites, though these sulphureous ores are no longer worked, on account of the deleterious effects occasioned by the operation. Stone is found in abundance and variety, particularly jasper and marble; but the houses are universally built of brick, because the use of stone, though abounding everywhere, is prevented by the expense of carriage in a country where the roads do not admit of wheel-carriages, and where there is no navigation. There is said to be a considerable mass of rock crystal near Ghoorkha, and limestone as well as slate abounds everywhere; yet there are no limekilns in the country, the only cement employed being mud, which, the natives pretend, answers better in their humid climate than mortar.

The alpine region belonging to Nepaul is about the same Moun- breadth of thirty or forty miles from north to south. Scat- tained peaks are here seen covered with perpetual snow, until, in advancing to the boundaries of Thibet, everlasting winter reigns. This inhospitable region consists chiefly of immense rocks rising into sharp peaks and tremendous precipices, covered with snow, and almost constantly involved in clouds. Some of these mountains are estimated to rise 25,000 feet above the valley of Nepaul. The rains here are periodical, as in the plains of Hindustan, and fall in the hottest season of the year. The snowy ridge of the Himalaya Mountains, though it has a winding course, has few interruptions, and is in most places impassable. Several rivers which take their rise in Thibet make their way through the mountainous ridges, but by such narrow chasms, and amidst such enormous precipices, that these openings afford no practicable communication between the mountains and the plains. In the mountain passes no sort of baggage or merchandise is transportable, except on the shoulders of hill porters. The price of this carriage is regulated by the government.

The numerous valleys which are interspersed through- out the mountains of Nepaul are inhabited by a variety of Popula- tion. mixed races. The aboriginal inhabitants appear, from their physiognomy, to have been of Tartar or of Chinese origin, and to have had no resemblance to the Hindus either in features, religion, or manners. Before their arrival they had no idea of caste. The period when these mountainous regions were first invaded by the Hindus is uncertain; but, according to the most authentic traditions, it is supposed to have taken place about the fourteenth century. The Hindus who now inhabit these mountains were about this

Nepaul. period driven from their country by the invasion of the Mahommedan sovereign of Delhi, who made proposals to marry a daughter of the rajah of Chitore, celebrated for her beauty. This offer was refused, and the consequence was that his city was captured and destroyed; and, to avoid the hated yoke of the conqueror, great numbers of the inhabitants fled to the mountains. Many of the chiefs amongst the mountain tribes, accordingly, claim descent from these Chitore princes, although on doubtful grounds. There are a few rajpoots whose claims to a pure descent from the Chitore family are allowed; and the families of the mountain chiefs who have adopted the Hindu rules of purity, and some even who have neglected this, are now admitted to be rajpoots; whilst, on the other hand, the purity of the Chitore blood has been so often contaminated by alliances with the Tartar and Chinese races, that several of the Chitore family have acquired the Tartar countenance, and some of the mountain tribes, by intermarriages with pure rajpoots in a low station, have acquired the oval faces and high noses of that remarkable race. The original purity of the rajpoot blood having been thus lost by indiscriminate alliances, all the hill chiefs, whether their descent from the Chitore family be real or pretended, are now called rajpoots, and hold the principal offices, civil and military, of the petty states into which the country was subdivided before Nepaul was subdued by the reigning family of the Ghoorkhas. In the eastern parts of the country the aboriginal tribes still remain; and, until the predominance of the Ghoorkhas, they enjoyed unmolested their customs and religion. But west of the Cali the case is different, almost all the inhabitants claiming a descent from the Hindu colony. They accordingly consist principally of the two superior classes of Hindus, or brahmins and chetrees, with their various subdivisions.

East of the Cali the tribes which possessed the country were chiefly, 1. Magars, who occupied the lower hills in the western parts, and were very soon converted to the brahmin doctrine of abstaining from beef. They are at present enlisted by the Ghoorkha sovereigns, and compose a great majority of their troops. 2. The Gurungs, a pastoral tribe, shift their abode between the mountains and the valleys with the summer and the winter. They still adhere to the lama priesthood and the Buddhist religion. They cultivate with the hoe, are diligent miners and traders, and employ the numerous flocks which they possess in conveying their goods to market. 3. The Jariyas form a numerous tribe, and inhabit the lower hilly region between the Cali and the Nepaul valley, and are now nearly all converted to the brahminical doctrines. 4. The Newars are an industrious people, following agriculture and commerce, and are more advanced in the mechanical arts than the mountain tribes. The greater part of them adhere to the tenets of the Buddhists: though they have adopted the distinctions of caste, they do not acknowledge the lamas, and have a priesthood of their own. The more fertile part of what is called Nepaul Proper was chiefly occupied by the Newars, a race addicted to agriculture and commerce, and far more advanced in the arts than any other of the mountain tribes. Their style of building, and most of their arts, appear to have been introduced from Thibet. All the Newars burn their dead; they eat buffaloes, sheep, goats, fowls, and ducks, and are addicted to the immoderate use of spirituous liquors. They live in towns or villages, in houses built of brick cemented with clay, and covered with tiles; these houses are three stories high, the ground-floor being allotted to the cattle and poultry, the second to the servants, and the third to the family of the owner. Their rooms are low, and have a mean and dirty appearance, and, besides, are infested with vermin, which, in addition to the filth, the offals of the shambles, and the blood of their sacrifices collected in the streets, give their towns an exceedingly offensive aspect

to Europeans. The Newar women are never confined to the house. At the early age of eight years they are carried to a temple, and married, with the usual ceremonies of the Hindus, to a fruit called *ull*; and when they arrive at puberty they are betrothed to a man of the same caste, and the parents give a dowry to the husband, or rather her paramour, their manners being extremely licentious. Like the women amongst the Nairs, they may in fact have as many husbands as they choose, being at liberty to divorce them as often as they please, and upon the slightest pretences. The Newars are peaceable, industrious, and even ingenious; much attached to the superstition which they profess, and now reconciled to the chains imposed on them by their Ghoorkha conquerors. Their occupations are chiefly those of agriculture; and they are, besides, almost exclusively employed in the arts and manufactures of the country. They are generally of the middle size, possessed of great corporeal strength, with broad shoulders and chest, very stout limbs, round and rather flat faces, small eyes, low and somewhat spreading noses, and open and cheerful countenances, with little or no resemblance, according to Kirkpatrick, to the Chinese countenance. The complexion of the women is somewhat between a sallow and a copper colour. 5. The Dhenwars and Mhanjees are the husbandmen and fishers of the western districts. 6. The Bhootias. Though some families of this race are planted in the lower lands, they occupy, generally speaking, such parts of the mountainous country as are included in the Nepaul territories. They shave their heads, and observe many idolatrous rites and customs. 7. The Bhanras are a sort of separatists from the Newars, and are supposed to amount to 5000. They observe many of the customs of the Bhootias. To the eastward some districts of the Nepaul dominions are inhabited by tribes, such as the Limboos, Nuggerkootees, and others, of whom little more is known than the names.

With regard to the number of inhabitants within the bounds of Nepaul, we have no data to form any thing like an accurate estimate. The wild and rugged nature of the country gives no ground to suppose that the population is considerable. It is in the valleys that the population is collected; and these, says Kirkpatrick, with the exception of Nepaul and two or three others, are little better than mountainous cavities. Even the Terriani, or low belt of land which runs along the southern frontier, is but indifferently peopled, the villages being, according to the traveller already mentioned, very thinly scattered, and mean both in their appearance and in their size. The Nepaulese themselves give the most exaggerated account of their numbers. They reckon their population by houses; and to Patan, their largest town, they assign 24,000 houses, to Bhatgong 22,000, and to Catmandoo 18,000. This would give a population of 640,000. There are, besides, many large villages and towns scattered around Kirtteepoor, containing 12,000 houses; Theamee, Buneba, Pharping, Punonlee, Dhulkill, Chappagang, all containing from 6000 to 7000 houses; and, besides these, there are reckoned between twenty and thirty smaller, of from 1000 to 4000 houses, all within the valley of Nepaul. But this gives a population that sets probability at defiance, and is considered, both by Frazer and Kirkpatrick, as a glaring fallacy. According to the latest accounts, the population of Nepaul is estimated at nearly two millions.

The lands are held by various tenures. Those constituting crown-lands, or the rajah's immediate estates, are property chiefly situated in the Ghoorkha territory, though there is hardly any portion of the Ghoorkha conquests in which the prince has not appropriated land to his own use. Some of these lands are cultivated by husbandmen, who receive a share of the produce; others are tilled by the neighbouring husbandmen, who are obliged to dedicate a certain

Nepaul. number of days in the year to this service. From such lands the rajah draws all the supplies necessary for the support of his household. The brahmins also possess lands, the title to which they receive by royal investiture. These lands are rent free, saleable, and hereditary; but they may nevertheless be alienated for certain crimes. Their proprietors are bound to the reigning prince for nothing beyond their prayers, though they sometimes consider it as prudent to conciliate him by more substantial gifts. Another tenure by which land is possessed by the Newars, is the payment of a considerable fine when the original titles are confirmed, which must be renewed on the accession of each prince. Other lands pay a rent to the crown, or to the jaghireदार (proprietor), in proportion to their produce. The khyra and barilands are those which are destitute of springs or running water, and which, requiring considerable labour, yield, after all, no very profitable return. These pay a rent according to their produce, which is estimated by the number of spades or ploughs employed. Widows may cultivate as much of this land as they can, without paying any rent at all. The kaith or plantation-lands, which are well supplied with water, and, being situated in the valleys, are fruitful, and yield all the superior kinds of grain, pay the half of their produce to the cultivator, who in return defrays all the charges of tillage, with the exception of the seed. These lands are reckoned to yield from twenty to thirty fold; and they pay different rates to the proprietor, according to the value of their produce.

Military force.

The whole population of Nepaul are liable to military service in times of public danger, though they are not regularly trained to arms. But there is a standing army dispersed over the country, besides a large force always in the capital, amounting to 30,000 or 35,000 troops. These troops are regularly trained, disciplined, and officered after the manner of European troops; and they likewise affect the European exercise, dress, and arms. The regular force of Nepaul has so long been accustomed to active service and to constant victory, that they have acquired all the qualities of veteran soldiers, a fearlessness of danger, and a contempt of any foe opposed to them. "They have," says Frazer, "much of the true and high spirit of a soldier, that setting of life at nought in comparison of the performance of duty, and that high sense of honour which forms his most attractive ornament, and raises his character to the highest." These qualities were frequently displayed in the course of the campaign with the British, against whose overwhelming attacks fortresses were defended with a determined bravery, and a patient endurance of famine and misery, that were truly exemplary. And when they at length surrendered a fort which was no longer tenable, they deplored their hard fate, called themselves wretched men that ought rather to have died, and refused to return to their native country; whilst the courtesy they showed to the British, and the reciprocal good offices received and returned, resembled more the generous spirit of European warfare, than the cruel practices of the East. The expenses of the military establishment are mostly defrayed by assignments of land, though in some instances the soldier receives his pay from the treasury, and occasionally from the public granary; others are paid partly in money, and partly in land; but the most usual mode, and the one most agreeable to the troops, is by putting them in possession of tracts of land, on which they generally settle their families, whom they can maintain better in this manner than by any pecuniary stipend. There seems no fixed rate of reward for different ranks, a good deal depending on the interest of the parties, and other incidental circumstances. One of the captains of the rajah's company of guards informed Colonel Kirkpatrick, that the lands which he held yielded him 180 rupees a year, and that he received an additional sum in money of 280 rupees; but added, that he was

Nepaul. better off when he belonged to a private company. It may be added, that government evinces great consideration for its military and public servants, being particularly indulgent to their widows, orphans, and other destitute branches of their families. The soldiers are in general stout, thick, and well-built men. They are very brave, and prefer close fighting, giving an onset with a loud shout. During the war with the British they attacked with great valour and impetuosity, advancing to the very muzzles of the cannon. They understand the use of the sabre; and each man wears, besides, a "cookree," or long crooked heavy knife, which may be used in war, but is also of great use in all common operations where a knife or hatchet is required. The soldiers also carry a long sort of matchlocks or muskets. The officers, besides the sword and shield and "cookree," carry bows and arrows, which they use very dexterously. The sword which they use has the edge curved inwards like a reaping hook, but far more straight, and very heavy, particularly at the point, where it is very broad, and ends abruptly square. A few small guns are used; but they are confined to the walls of forts, and never carried into the field.

The government of Nepaul is essentially a despotism, Government. and is good or bad according to the character or temporary views of the reigning prince. It is no doubt slightly ameliorated by the authority of immemorial customs, and the influence of religion, which no prince, however despotic, can safely disregard; as well as by the occasional opposition of the aristocracy or chiefs. But the great body of the people derive little benefit from the struggle for power between the prince and his nobles. They seem to possess no civil rights, and are at the mercy of their rulers for whatever treatment the latter think proper to give them. It was observed by Kirkpatrick, in the course of his journey into the country, that the carriers were pressed, without ceremony, into the service of government, and compelled to work without any promise of pay; and in the war with the British, a detachment of troops, because they yielded a post to the enemy which they could no longer hold, were punished with extraordinary cruelty, being mutilated in their faces in the most shocking manner. In Europe the progress of improvement has modified the rigour of the most absolute governments; but in Nepaul, as in all the Asiatic states, despotism grows up to the most frightful maturity in the congenial soil of ignorance; and although the arbitrary will of the prince may be opposed by the force of circumstances, yet there is no permanent security for life and property, such as is derived from the authority of fixed laws. The administration of public affairs is carried on by various officers. The first of these is the choutra or prime minister to the rajah, to whom he is invariably akin. His business is to receive and examine all written and verbal communications regarding public business, and to act as a sort of comptroller-general over the inferior departments of administration. He holds his office during the pleasure of the prince, to whom he submits all his reports on matters of state; and the former, if he see proper, refers them for further investigation to a court of inspection appointed for the purpose. He is paid by a commission or fine on every rice plantation, with the exception of those of the Thurgars or nobles and the military. Secondly, the kajeas are four commissaries who superintend all civil and military affairs, and are employed in the collection of the revenue, and in the management of the Jaghire lands. They are paid by a tax of one rupee on all taxable lands. Thirdly, the sirdars command the armies of the state, and likewise participate in the management of civil business. Fourthly, the kurdars act as secretaries, preparing all communications from the rajah to foreign powers, or to the officers of state. Fifthly, the kuperdar and the kuzanchees have the charge, the one of the

Nepaul. rajah's private wardrobe, jewels, and kitchen; and the other of the public wardrobe, from which honorary dresses are issued. All these officers are paid by a moderate duty upon all taxable lands. Sixthly, the ticksali or superintendent of the mint is paid by a commission on the import duties from Thibet, and on a tax payable by all natives of Nepaul who return to their country from Lehassa, Diggercheh, or other parts of Thibet. This tax is exacted with a good deal of rigour. Seventhly, the dhurmaudhikar is the chief criminal judge, who commissions all the inferior judges, excepting those who officiate in the farmed districts. The fees in this department are very great; and as most crimes are punishable by fine, the penalties constitute a large source of emolument, which does not by any means favour the pure administration of justice. Civil questions regarding property are decided by another tribunal, the members of which are usually brahmins. Over this court the criminal judge sometimes presides. Intricate questions are occasionally referred to a superstitious ordeal, in which chance decides; and this barbarous process is a sure index to the manners of the people, and to the low state of their civil institutions. There is, besides, a superintendent of the police, a minister who is employed in complimentary embassies to foreign powers, or in carrying orders to public officers. The soubahs are governors of districts, or farmers, and government collectors, acting as officers of revenue, of justice, and of police; and the omrahs are commanders of military posts.

Revenue.

The public revenue is derived from land-rents, customs, fines of various sorts, and from mines. Annual presents are made by the soubahs, and by every one who approaches the court; and a sort of arbitrary income-tax is besides levied from all ranks, even the sacred order, who possess free lands, not being exempted. An officer is often employed for the express purpose of collecting this tax, which is rated according to the exigencies of the state, and which mounts up in many districts to more than the regular revenue. According to Colonel Kirkpatrick, who visited the country in 1792, and who derived his information from good authority, the revenue actually remitted to Catmandoo never exceeded thirty lacs of rupees (L.300,000), but it sometimes fell to twenty-five lacs. The subsequent conquests by the Ghorkha sovereigns were not productive of a great increase of income; and the reduction of territory by the last war would of course occasion a corresponding diminution. The export duties, and the profits on the sale of elephants, bring in from three to four lacs of revenue. The import duties levied on the trade from Thibet, included under the mint, as the returns consist chiefly in silver bullion, amount to about seven or eight lacs. The duties on salt, the profits on saltpetre, which appears to be a monopoly, on copper and iron mines, and the produce of the land-tax, may be estimated at from fifteen to eighteen lacs. Formerly the inhabitants of Thibet were supplied with a silver currency from the mint of Nepaul, on which the treasury gained a profit of a lac of rupees.

Trade.

The trade of Nepaul is by no means so extensive as it might be if it were conducted under proper regulations; being shackled by monopolies for the benefit of government, or of a few favoured merchants, who labour to preserve their privileges by the most invidious and corrupt means in their power, and by other injudicious restraints. But, at the same time, the surplus produce of so poor a country could scarcely afford the basis of an extensive trade; and it was accordingly rather the medium of communication between other countries, than remarkable for the extent of its own commerce. Formerly merchants from Cashmere carried their manufactures to Kutti and other towns in Thibet, and received in return the wool produced in these countries from the shawl goat. Such portions of these manufactures as are not used in Thibet

were exported by the way of Teshoo Loomboo and Lassa, Nepaul, to Siling or Sining on the frontiers of China, and partly sent to Catmandoo by way of Patna. The principal goods imported in return to answer the demand of Cashmere and Nepaul were teas and silks; and from Patna, it is said, they exported otters' skins to a great amount, procured from the neighbourhood of Dacca. The articles imported into Nepaul from Thibet are coarse woollen cloths, paper, horses, sheep, shawl goats, chowry bullocks, chowries or cow-tails, musk-deer, dogs, falcons, pheasants, salt, sal-ammoniac, hortal or yellow arsenic, borax, quicksilver from China, gold in grains and in small lumps, antimony, rugs or coarse blankets, munijheet or Indian madder, cherris or extract of hemp, besides various medicinal drugs and preserved fruits, such as almonds, walnuts, raisins, dates. Of these articles, the greater part of the musk, chowries, hortal, borax, and bullion still find their way to Patna; whence in return are sent north, buffaloes, goats, broad cloth, cutlery, glass ware, and other European commodities, Indian cotton manufactures, mother of pearl, pearls, coral, beads, spices, pepper, betel nut and leaf, camphor, tobacco, tin, lead, zinc, and phajoo, the red powder thrown by the Hindus during the hooly. Besides these articles, utensils in wrought copper, brass, bell-metal, and iron, are sold to the merchants of Thibet. The borax and salt are said to be brought from a lake which is situated nearly north from Catmandoo, about fifteen days' journey beyond the Brahmaputra. The carriers of these articles are a large kind of sheep, with four horns, which appear to be the common beasts of burden in all countries towards the sources of the Indus, Ganges, and Brahmaputra. Formerly the lamas of Lassa and Teshoo Loomboo sent a large sum in bullion to be coined at the mint of Catmandoo, on which an allowance of four per cent. was made for the coinage. But the rapacity of the rajah induced him to alloy the rupee to the amount of eight per cent., which had the effect of putting an entire stop to this source of revenue.

The Newars are almost the only artisans in Nepaul; **Manufactures** and they appear to be acquainted with and to exercise most of the handicraft occupations of their neighbours. The Newar women of all ranks, as well as the men, of the hill-tribe of Mugar, weave two sorts of cotton cloth, partly for home use and partly for exportation. These cloths are the dresses of the middling and lower classes, although woollens would be much better fitted for the cold climate of a Nepaul winter. Those, accordingly, who are not very poor, wear woollen blankets, which are manufactured by the Bhooteas, who wear nothing else. The dress of the higher ranks is not manufactured at home, but is imported, consisting of Chinese silks, shawls, low country muslins, and calicoes. European broad cloth is worn by the military alone. They work very well in iron, copper, brass, &c.; and in Lalita, Patan, and Bhatgong, there are considerable manufactories of these articles, and also of a species of bell-metal. One bell which was manufactured at that place measured five feet in diameter. The Thibet bells are superior to those of Nepaul, though a great many bell-metal vessels are made by the Newars, and exported to Thibet, along with those of brass and copper. They are likewise particularly ingenious in carpentry; but it is remarkable that they never use a saw, dividing their wood, of whatever size, by a chisel and mallet. They are skilful in gilding; and they manufacture at Bhatgong, from the bark of a shrub, a very strong paper, remarkably well suited for packages. They distil spirits from rice and other grains, and also prepare a fermented liquor from wheat, munoo, rice, &c. which they call jhaur. It is made somewhat in the manner of malt liquors, but is more intoxicating. The Newar peasants use it in the same manner, and consider it as necessary for their comfort as the labouring people of Britain do porter.

Nepaul.
History.

The early history of Nepaul, like that of most of the eastern countries, is buried under a mass of fable. The inhabitants exhibit a list of princes for several thousand years back, which is given in Colonel Kirkpatrick's work, but without any evidence of their authenticity. It is doubtful whether such persons ever existed. We know, however, that Nepaul was the scene of important revolutions, though it never was subjected to the Delhi emperors, or to any of the other great Asiatic powers. It is said to have been completely subdued in A. D. 1323, by Hurr Singh, one of the princes of Oude, who was driven out of his own possessions by the Patans. But from that period there exists no accurate information respecting the dynasties which ruled during the interval, or the race of princes who governed Nepaul at the time of the Ghoorkha conquest. Runjeet Mull was the last of the Surya Bansi race, or children of the sun, that reigned in Nepaul. He formed an alliance with Purthi Nirain, which ended in the loss of his dominions, of which he was stript by his ally in the Newar year 890 or 888, corresponding to A. D. 1768. He possessed great courage and insatiable ambition, and was indebted for his success in war to his introduction of firelocks and European discipline amongst his troops. It was in his reign that Captain Kinloch, with a British force, endeavoured to penetrate into Nepaul. But, from the sickness of the troops, and the difficulty of the country, the enterprise was abandoned. Purthi Nirain died about three years after the final conquest of Nepaul, that is, in the year 1771. He left two sons, Singh Pertaub and Behadur Shah, the former of whom succeeded to the throne, and, conceiving a jealousy of his brother, threw him into prison, whence he was with difficulty released by the interference of one of the spiritual guides of the Ghoorkha family, on condition that he should live in exile. Singh Pertaub, after having extended his father's conquests, died in 1775, leaving one son, who was an infant. Behadur Shah, on the death of his brother, returned from his exile to Catmandoo, and, having placed his nephew on the throne, assumed the office of regent. But the mother of the infant prince, Rajender Letchemi, contrived to supplant Behadur Shah in his office, and even to secure the person of her rival. Through the mediation, however, of one of the priests, an accommodation took place, and Behadur Shah was thus enabled to seize and confine the ranee in his turn. Neglecting, however, to conciliate the chief men of the state, he was again driven into banishment, from which he did not return till the death of the princess, when he re-assumed the regency without opposition. In the course of his administration, Palpa, and many other petty states to the westward, Bhote to the north, and Sikkim to the east, were compelled to submit to the rule of the Ghoorkhas.

Towards the close of the administration of Mr Hastings in India the Ghoorkha sovereigns were involved in hostilities with Thibet, and finally with China. The Teshoo Lama of Thibet having proceeded to Peking, died soon after his arrival in that city. His brother, Sumhur Lama, taking advantage of his absence, fled from Lassa to the rajah of Nepaul, carrying along with him a considerable quantity of treasure; and he made such representations to the Nepaul government that their avarice was inflamed, and having marched a body of troops to Lassa, they extorted from the lama a tribute of three lacs of rupees. In 1790 they despatched to Teshoo Loomboo, the residence of another sacred lama, a second body of troops, amounting to 7000 men, who pillaged the place and the sacred temples, and succeeded in carrying off a large booty, though closely pursued by a Chinese army, and though, from the severity of the weather, they lost 2000 men in their retreat. The emperor of China, as the terrestrial superior of the lamas, and their worshipper and protector, incensed by these unprovoked aggressions, despatched an army of 70,000 men

Nepaul.

against the Nepaulese, who were overthrown in repeated battles; and the Chinese army advanced to Noakote, within twenty-six miles of Catmandoo, and sixty of the British territory of Bengal. A peace was at last concluded, though on terms ignominious to the Nepaulese, who were compelled to become tributaries to the Chinese, and to refund the spoil which they had taken from the Thibet lamas. It does not appear, however, that this tribute was ever exacted. It was about this period that Lord Cornwallis attempted to conclude a treaty of commerce with the Nepaulese; but every proposition of this nature was frustrated by their extreme jealousy.

The queen-regent died in 1786, when the care of the young rajah devolved entirely on his uncle Bahadur Shah, who was accused of having, from disgraceful motives, encouraged the rajah in his debaucheries, in hopes of bringing him into contempt, and of thus securing to himself the reins of authority. In this expectation, however, he was deceived, as the rajah, in 1795, when he had entered into his twentieth year, suddenly announced to his uncle that he had now resolved to assume the reins of government, and being supported by a large proportion of the nobles, Bahadur Shah, making a virtue of necessity, forbore all resistance, and received in return assurances of the most distinguished favour. The young rajah rendered himself extremely popular during the first year of his reign. But this fair prospect was speedily overcast, and the youth plunged into all the excesses of the most furious despotism and cruelty. His first act was to arrest his uncle, and, loading him with chains, to throw him into prison, where he was starved to death. He daily tortured and mutilated his subjects, and beheld their sufferings with savage joy. In his outrages he made no distinction of age or sex. Women of all castes, even those belonging to the sacred orders, were seized, and subjected to abuse from the vilest characters. In 1797, he had a son by a brahmin widow, who being taken seriously ill next year, and finding her end approaching, reminded the rajah of the prediction of astrologers, that he would never complete his twenty-fourth year, and entreated that he would provide for the unprotected orphan they were about to leave. The rajah, relying implicitly on the superstitious prophecy, immediately, and in the most solemn manner, before all the chiefs, abdicated the throne in favour of his son, though illegitimate, and an administration was then appointed, over which one of his ranees or queens was appointed to preside. The abdicated monarch now devoted his whole time to attendance on his favourite widow, who, notwithstanding all his attention, and rich offerings at the different temples, soon afterwards expired. In his affliction he became quite frantic, and perpetrated atrocities, the bare mention of which causes the Nepaulese still to shudder, and which are too shocking to be narrated. Amongst various enormities, he directed the sacred temple of Bahvani to be demolished, and the golden idol, which was a venerated object of worship, to be ground to dust; and when the soldiers to whom he had issued the orders demurred at such an act of sacrilege, he commanded boiling oil to be poured on their naked bodies. Nor were any exempt from his rage. Neither rank nor caste afforded any protection from his violence. Even the first members of the government were scourged without mercy, and otherwise tortured. A confederacy was at last formed against the tyrant, who finding himself abandoned, absconded during the night, and fled to Benares, which he reached in May 1800.

A close connection with Nepaul had always been a favourite object with the British rulers of India, and the flight of the rajah to Benares appeared to present a fair opportunity for bringing it about. A treaty of alliance was accordingly concluded between the two states, by Captain W. D. Knox, who was appointed ambassador,

Nepaul. and who proceeded to Catmandoo for the purpose in 1802. The terms of the treaty were considered as favourable to the British interests; the Nepaulese being anxious to secure the influence of such powerful neighbours against the faction of the abdicated rajah, who still contended for his restoration. But whatever advantages were attained by this treaty, were ultimately rendered nugatory by the jealous opposition of the subordinate officers amongst the Nepaulese, who were probably instigated by their chiefs, the latter being entirely unable to fulfil the obligations which they had entered into.

The residency at Catmandoo was accordingly withdrawn in the year 1804. About this time the abdicated monarch, Run Bahadur, by the able management of his queen, whom he had always ill treated, was restored to his former authority. But as he continued to rule with his former barbarity, his reign was of short duration; in 1805 a conspiracy was formed against him, which terminated in his assassination. His death was succeeded by the most violent conflicts between the adverse parties in the state, and did not terminate until nearly the whole of the nobles at Catmandoo had perished. The surviving adherents of the late rajah having at length secured the person of his son, seized on the reins of government, putting to death such of the opposite party as still remained.

But during all these intestine commotions, it is remarkable that the Nepaulese still extended their conquests on every side. To the west of Catmandoo, and towards the Sutlege, the hill-chiefs were distracted by mutual jealousies, and by no means in a condition to form a league for their mutual defence. They were accordingly subdued one after another by the armies of the Ghoorkhas, who very soon made themselves masters, without the aid of artillery, of every hill-fort, from the Ganges to the Sutlege. When their movements first attracted the notice of the British government, their chief was vigorously prosecuting the conquests of these states; and as he advanced westward, he erected strong forts and stockades at convenient positions, namely, Almorah, Serinagur, and Malowa. The Sikh frontier was also guarded by a strong line of fortified posts; and thus the consolidation of the Ghoorkha empire proceeded with a slow but sure progress. The extensive tract which lies between Catmandoo and the Sutlege was held in firm subjection by a strong military force, whilst to the east the Sikkim rajah was deprived of half his territories, and compelled to pay a tribute for the remainder. To the north the progress of conquest was restrained by the Chinese power, with which the Ghoorkha chiefs had already found themselves unable to cope, and also by a lofty range of barren mountains. But the fertile and low situated plains of the south presented a more alluring prospect, and greater probabilities of success in a contest with a new and untried power. The consequence was a series of encroachments along the whole northern frontier of the British possessions, especially in the district of Gorruckpoor and Sarun. The British remonstrated against these proceedings, and an investigation into the respective claims of the two powers was commenced by commissioners jointly chosen, the result of which being entirely favourable to the British, a detachment of regulars was ordered to take possession of the debateable ground. But these being withdrawn during the rainy season, the chief police station upon the frontier was attacked by large bodies of Nepaulese, and the officers were compelled to fly, with a loss of eighteen killed and six wounded. Shortly afterwards a second attack was made on another police station, and several persons were killed, after which the whole body was withdrawn; and, in 1814, the war commenced. A brief account of the operations of this war will be found under the article HINDUSTAN; and it is only necessary here to state generally, that the invasion of the Nepaulese dominions was

commenced on the western frontier, beyond the Jumna **Nepaul.** and near the Sutlege, the country there being considered as of easier access than the mountainous barrier which bounds the Nepaulese dominions on the side of Bengal. But the British troops, in attempting to storm the stockades and hill-forts, were repeatedly driven back with severe loss, and suffered reverses to which they had been wholly unused in the wars of India. Here it was that the brave General Gillespie was slain, whilst he was encouraging his troops, who had been repulsed, to renew the attack. In 1815, Sir David Ochterlony assumed the chief command, and by a series of skilful operations, in which he dislodged the Ghoorkha troops from the fortified heights of Malowa, and ultimately so hemmed in their renowned commander Ameer Singh, and his son, that they were forced to sign a capitulation, by which they agreed, on being permitted to retreat with their remaining troops, to abandon the whole territory west of the Cali branch of the Goggra. In Kumaon also the British troops succeeded in driving the enemy before them; and, in consequence of these successes, a definitive treaty of peace was signed on the 28th of November 1815. But the signature of the rajah being withheld, it was determined to renew the war, and to strike a decisive blow directly at the capital of the country. Preparations for this arduous enterprise were made on a great scale, a force being assembled at Sarun amounting to about 13,000 men, of whom 3000 were Europeans, besides a large body of irregulars, amounting in all to above 46,000 troops. This formidable force took the field in the end of January 1816, and advanced from the Bettiah district directly on Catmandoo. The greatest difficulties were encountered, from the ruggedness of the country, in marching along the dry beds of torrents, through ravines, and in the face of precipices. But all these obstacles were overcome by the patience of the troops, and the consummate skill and science of their commander. The Ghoorkhas made a brave resistance, but they were overthrown in several severe encounters; and the British force had now approached within three days' march of their capital, Catmandoo. Deeming all further resistance vain, an ambassador was sent to the British head-quarters, to sue for peace; and the unratified treaty of the year 1815 was accordingly duly signed. By this treaty the Nepaulese renounced all claims to the territory in dispute. They also ceded all the conquests which they had made to the west of the Cali branch of the Goggra, and which, with the exception of Kumaon, the Deyrah Doon, and some other portions of territory annexed to the British dominions, were restored to the families of the chiefs who had reigned there prior to the Ghoorkha invasion, and who were now to rule as vassals of the British; it being understood, however, that the latter were not to interfere in the internal administration, but were merely to act as arbiters between rival chiefs.

In the course of this contest with the British, the Nepaulese had earnestly entreated the aid of the Chinese against the Europeans, whom their ambassadors represented as desirous of acquiring Nepal merely to serve as an intervening point in their progress to China. Their application being transmitted by the grand lama to Peking, an answer was received, in which the emperor expressed his conviction that the Ghoorkhas had themselves been the cause of the war by their unjust encroachments, and declined all interference. After peace was concluded, the Chinese emperor expressed deep offence against the rulers of Nepal, who, being merely tributaries, had presumed to make war or peace with the British, without the sanction of their superior; and, to back those lofty pretensions, an army of 15,000 men, commanded by five generals, and attended by Chinese functionaries of superior rank, usually stationed at Lassa, actually advanced towards the Nepaulese territories. At the request of the Nepal ministers,

Nepos. the British consented to act as mediators. But in the meantime they themselves despatched to the Chinese camp agents, who having reached it early in September 1816, succeeded in bringing about the restoration of peace, and of all the ancient relations between the two powers. In 1816 Ameer Sing Thappa, one of the most distinguished Ghoorkha commanders, who had so gallantly disputed the field with Sir David Ochterlony, died at the age of sixty-eight. To the last day of his life he was endeavouring, by negotiation and by every art, to excite amongst the different states a spirit of hostility against the British, as the common enemies of Indian independence. Two of his widows devoted themselves to death along with him; one sacrificed herself on the spot, and the other was at the same time preparing for the fatal pile at the temple of Pushpoo-nath, within the valley of Khatmandu. In November 1816 the young rajah died of the small-pox, at the age of twenty-one years. One of his queens and one of his concubines, together with five female attendants, devoted themselves to the funeral pile along with the corpse. He left one son, three years of age, named Rajindra Bickram Shah, who succeeded quietly to the throne, under the guardianship of the minister Bheern Singh Thappa; a very unusual circumstance in the annals of Nepaul. From this time the history of Nepaul presents little that can excite interest in a European mind. Intrigue, and occasional resort to rougher means, identify its character with that of most Asiatic courts. At intervals, however, events have occurred which, by their unusual atrocity, relieve the tameness of the surrounding incidents. Such events have marked the career of the present prime minister, Jung Bahadoor, whose name is well known in England, which country he visited some years since. Jung Bahadoor was the nephew of a man who had elevated himself to a high position in the administration of affairs. Upon the murder of his uncle, which was perpetrated at the instigation of the queen, a new ministry was formed, and Jung was appointed to the command of the army. Shortly afterwards, the new premier was assassinated, and the queen, with whom he was a prime favourite, demanded vengeance. Jung Bahadoor undertook the task, and executed it with alacrity. An assembly of chiefs and nobles being convened within the palace, Jung, backed by a small force on which he could depend, suddenly appeared among them, and a general massacre raged throughout the building. Fourteen of the hostile chiefs fell by the hand of the commander-in-chief; but the bodies of his victims were for Jung the stepping-stones to power. Before the dawn of the succeeding day Jung Bahadoor was invested with the office of prime minister. His future career was not inconsistent with its commencement. A conspiracy was formed for his destruction; but Jung not only escaped, but seized and beheaded all the adherents of the chief conspirator. The queen was banished with her two younger sons, and the king having accompanied them, the heir-apparent was raised to the throne. A feeble attempt was made by the monarch to regain his throne, but the energy of Jung baffled it, and the king was made prisoner. Jung Bahadoor has always professed a friendly feeling towards the British; and at the commencement of the great military revolt in 1857 (the particulars of which will be found under the article NORTH-WESTERN PROVINCES OF BEN-GAL), he proved the sincerity of his friendship by reinforcing the British army with a contingent of Ghoorkha troops.

(D. B.—N.) (E. T.)

NEPOS, CORNELIUS, a Latin writer, who was the friend of Cicero, Atticus, and the poet Catullus, and flourished B.C. 40. It is uncertain where he was born, but Pliny (iii. 22, 2) calls him *Padi accola*; and his friendship with Catullus makes it not improbable that Hostilia, near Verona, where that poet was born, was also his birth-place. We possess no information respecting his private life; but many of

his works are cited by later writers. 1st. His *Chronicles* or *Annals*, probably in three books, of which the fragments do not enable us to decide whether they were confined to the history of Rome, or included that of all nations. Some have asserted that this was a mere translation of the work of Apollodorus on the same subject; but they have no sufficient grounds for so believing. 2d. The *Exemplorum Libri*, of which the fifth book is cited by Aulus Gellius (vii. 18), and which seems to have been a work containing remarkable transactions selected from history; but this may have been only another title for his work. 3d. The *Lives of Illustrious Men*, of which the sixteenth book is cited, and the lives we now possess, no doubt formed a part. 4th. The *Lives of Historians* (Nep. Dion. iii.), which included both Greek and Latin. It seems not unlikely that the biographical sketch still remaining of Atticus, and the longer one of Porcius Cato, which he mentions (Cato, iii.), belonged to this collection. 5th. The *Letters to Cicero*, which must have been published, as some of them are quoted by Lactantius (*Inst.* iii. 15). It would appear that he had also made successful attempts in poetry (Plin., *Ep.* v. 3). We possess a work under the name of Nepos, *Vitæ Excellentium Imperatorum*, which is not mentioned by any ancient writer under this title. It contains short biographical sketches of twenty commanders, mostly Greek; an essay, *De Regibus*, which is little else than the mere names of Greek and Persian kings; and the lives of Hamilcar and Hannibal. There are also two other biographical sketches of Atticus and Cato, which used to be separated from the rest, because they were not found in all the manuscripts, or, when found, were entitled *Ex libro Corn. Nepotis de Latinis Historicis*; whilst the others used to be considered as the work of a certain Æmilius Probus, whose name was found in all the manuscripts. This Æmilius Probus was long considered as a contemporary of Nepos; but he is now generally believed to be the *præfectus prætorius* to whom Ausonius addresses his sixteenth epistle, and is supposed to have lived in the reign of Theodosius, A.D. 370. At first, however, this work appeared under the name of Probus, and was thus published in 1471, and in the following editions, till 1563. Gifanius, in 1566, first directed the attention of the literary world to Nepos as the author; and subsequent investigation has nearly set the question at rest. Attempts have, however, been made to revive the old opinion, on the authority of the manuscripts and of the poetical address or dedication, on the silence of ancient writers to whom these lives seem to have been unknown, on several mistakes in history and chronology which appear in the work, and on the language, which is alleged to be unworthy of the golden age of Roman literature. (See the dissertations on this controversy prefixed to the editions of Lambinus (1569), Titze (1813), Bardili (1820), Dähne (1827), Roth (1841), and Benecke (1843). The most useful editions are those of Van Staveren (1773), Tzschucke (1804), Bremi (1820), and particularly Lemaire (1820). These biographies have always been exceedingly popular as a school-book; and the translations of them into various languages are numberless. The first English version was executed by "various gentlemen of the university of Oxford," London, 1684.)

NEPOS, *Julius*, a Roman emperor of the West, was invested with the purple by Leo I. in 473, was expelled from the throne by Orestes in 475, and was assassinated near Salona by two of his own officers in 480. (See ROMAN HISTORY.)

NEPTUNE (in Lat. *Neptunus* or *Neptunus*, in Gr. *Poseidon*), the god of the sea, was the son of Kronos and Rhea, and the brother of Jupiter and Juno. The etymology of the Greek as well as of the Latin form of his name is very obscure and doubtful. The ancient Dorians wrote the word *Poteidan*, in which some scholars find the same root as in *Potos* and *Potamos*, and the verb *pino*.

Nepos
||
Neptune.

Nerbuddah Cicero derives the Latin name of the deity from the Greek *nao*, the Latin *nato*; Varro, with still less show of probability, from *nubo* or *obnubo*, on the ground that the god covers or surrounds the earth with his waters. The most feasible explanation seems to be that which connects the name Neptunus with the root *nip*, as found in the Greek *nip̄to*. When the dominions of Kronos were divided among his sons, the sea fell to Neptune as his share. He was therefore worshipped with peculiar solemnity by all maritime nations; from the earliest ages by the adventurous Ionians, and at a later period by the Dorian Greeks. His favourite abode was said to be a splendid submarine palace at *Ægæ*. Among the principal seats of his worship may be mentioned Cyrene, *Ægina*, Corinth, and Troezen, whence it was transferred to the Italian peninsula, first to Sybaris, and afterwards to Posidonia or Pæstum. The Isthmian games, held in his honour at Corinth, ranked among the four national festivals of the Greeks. (See *ISTHMA*.) Neptune plays an important part in some of the ancient myths. He helped Apollo in building the walls of Troy for Laomedon. In his contest with Minerva for the honour of giving name to the city of Athens, he produced the horse. On this account he was regarded both by Romans and Greeks as a kind of equestrian as well as marine deity. The Romans had horse-races in the circus during his festival, when all other horses were crowned with wreaths and allowed a short respite from labour. The animals most commonly sacrificed in his honour were bulls, rams, and boars. Besides his favourite Amphytrite, by whom he had his son Triton, Neptune had two other wives, Salasia and Venilia. His statues represent him as a heavy and powerful figure, with tangled hair, and inferior in dignity of expression to his brother Jove. In his right hand he holds the trident, and with his left guides the horses yoked to the shell which serves him for a car. A long train of tritons and sea-nymphs follows in his wake.

NERBUDDAH, a large river of Hindustan, rising in the province of Gundwana, which, after a course of 750 miles, falls into the Gulf of Cambay. This river has its source close to that of the Soane, on the elevated plateau of Amarakantak, or Omercuntuc, at an elevation of between 3000 and 4000 feet above the sea. A Hindu temple is found in the centre of the table-land at Omercuntuc; and here the Nerbuddah rises from a small well, and flows easterly in a smooth stream until it is precipitated from the brow of the table-land. From this point its course is due W., with the straightest course of any river perhaps in the world. It passes through Gundwana, Khandesh, Madwah, and Guzerat, and after passing the city of Broach, falls into the Gulf of Cambay, in Lat. 21. 35., Long. 72. 35. This river was in former times the boundary between Hindustan proper and the Deccan or southern peninsula. Ships of burthen can proceed up the river to Broach, where it is a noble sheet of water 2 miles wide, even when the tide is out; but skilful pilotage is necessary in consequence of numerous sandbanks. The practicability of improving the navigation by artificial means has been considered, and some years since instructions were sent out for a survey by a competent officer with a view to this end.

NEREIDS. See *NYMPHS*.

NEREUS, a sea-god, son of Pontus and Ge, and father of the Nereids, the marine nymphs of the Mediterranean. His wife was Doris, the daughter of Oceanus. He is described as a wise and kindly deity, and especially skilled in divining the future. (Hor., lib. i., carm. 15.) His favourite haunt was the *Ægean Sea*, in which he lived with his daughters. The number of these nymphs is variously given as fifty or a hundred. (See *NYMPHS*.)

NERI, FILIPPO DE, the founder of the congregation of the "Priests of the Oratory," was born of a noble family in Florence in 1515. From his childhood he was noted for a

kind and pious disposition. This trait in his character began to appear in greater distinctness when he had completed his elementary education, and removed to Rome at the age of nineteen. But it was not until his twenty-fourth year that his religious charity assumed the form of active Christian philanthropy. At that time he abandoned his classical and theological studies, sold his books that he might give the money to the poor, and resolved to devote the rest of his life to doing good to the bodies and souls of his fellow-men. A deep sense of sin would not permit him to enter into holy orders. He was therefore content, in the unconsecrated garb of a layman, to relieve the needy, to console the sick and the dying, to visit the prisoners in their cells, to plead the cause of the oppressed in the courts of justice, and to instruct the ignorant in the street and by the wayside. The most notable of his many benevolent deeds at this time was the erection of an asylum for sick and destitute strangers. In 1551 Neri, being persuaded at length to enter the church, saw the circle of his influence beginning to widen. Several young ecclesiastics, including Baronius and others, who were afterwards celebrated, began to gather around him, and to aid him in his philanthropic labours. These he formed, in 1564, into an order, which, from the Italian name for a chapel, was called the "Congregation of the Priests of the Oratory." He laid upon them no monastic vows, but trusted that the common spirit of charity by which they were animated would be a living bond of union between them. The new order soon became distinguished for its Christian zeal and enterprise. In 1575 Pope Gregory XIII. recognised its usefulness by formally bestowing upon it his sanction. Its founder had the satisfaction in his old age of seeing it established in the principal Italian towns. In 1593 he resigned the generalship of the Oratory in favour of Baronius. He died in May 1595. Filippo de Neri was canonized by Gregory XV. in 1622. His life has been written in Latin by Gallonio, 8vo, Rome, 1602; and by Bacci, 4to, Rome, 1645. His letters were published in 8vo, Padua, 1751; and his treatise called *Ricordi*, and several of his poems, appeared in the *Rime Oneste*.

NERJA, a town of Spain, province of Malaga, on the Mediterranean, 13 miles E. of Malaga. It is well and regularly built, with broad paved streets and three squares; and has a parish church, a town-hall, and three schools. Manufactures of flour, sugar, linen, and paper, are carried on; and there is some trade in corn, oil, sugar, and fish. Pop. 4595.

NERO, a cognomen of the gens Claudia, one of the most illustrious patrician families of ancient Rome. The word, according to Suetonius, is of Sabine origin, and signifies "fortis" and "strenuus." Thus, *Nerio*, *Nerius*, or *Nerius*, personified "Bravery," was the name of the companion and wife of Mars; and in the Umbrian language, the often-recurring *Nerf* or *Neris* is explained *princeps*. The most distinguished persons who bore this name were,—

1. *C. Claudius Nero*, who signalized himself in the second Punic war by his successes against Hannibal, and, above all, by his splendid victory at the Metaurus (b.c. 207) over Hasdrubal, which completely broke the Carthaginian power in Italy.

2. *Claudius Drusus Nero*, the stepson of Augustus, and younger brother of the Emperor Tiberius. In the year b.c. 15, Drusus Nero, then only in his twenty-third year, subdued the Rhæti and Vindelici, and during his consulship, six years later, commanded the Roman armies in Germany, where he died. His wife was Antonia, the daughter of Mark Antony the triumvir, and by her he had three children, Cæsar Germanicus, the Emperor Claudius, and Livilla. (Hor., lib. iv., carm. 4.)

3. *Claudius Cæsar Nero*, the sixth of the Roman emperors. His original name was Lucius Domitius. His father

Nerja
||
Nero.

Nertshinsk was Domitius Ahenobarbus, and his mother Agrippina, the daughter of Germanicus. He was born at Antium in Latium A.D. 37, succeeded Claudius as emperor A.D. 54, and died A.D. 68, in the thirty-second year of his age and fourteenth of his reign. (See ROMAN HISTORY.)

NERTSHINSK, a town of Siberia, in the Transbaikalian territory, at the confluence of the Nertsha and the Shilka, 540 miles E. by S. of Irkutsk, and about 400 E.N.E. of Kiachta. It is wretchedly built of wood, and consists of an old and a new town, at some distance from each other. There are several churches; and some trade is carried on in furs. The district of Nertshinsk is rich in mines of gold, silver, and lead, in which a great number of men are employed. It also affords good pasturage. Pop. of the town (1851) 4993.

NERVA, MARCUS COCCÆIUS, the thirteenth emperor of Rome, was born at Narnia in Umbria A.D. 27, or, according to other authorities, in A.D. 32. He succeeded to the purple on the assassination of Domitian, September 18, A.D. 96, and, after a mild and equitable reign of sixteen months and nine days, died early in the spring of A.D. 98. Before his death he had adopted Trajan as his successor. (See ROMAN HISTORY.)

NERVES. See ANATOMY, and PHYSIOLOGY.

NERVII, a nation of Belgica, whose territory was situated N. of the Ambiani, are first mentioned by Cæsar at the date 57 B.C. At that time they were a simple-living, warlike, and patriotic people, abjuring all commerce with other nations, prohibiting wine and other luxuries from being imported into their territory, and zealously stirring up their neighbours to resist the coming invasion of the Romans. On receiving intelligence that Cæsar was advancing into their country, they sent away their old men, women, and children to a place of refuge among the marshes by the sea-shore, and posted themselves in ambush on the banks of the Sabis (*Sambre*). The invaders had approached close to the place of concealment, and, unsuspecting of any danger, were engaged in forming a camp, when they suddenly found themselves attacked by 60,000 fierce barbarians. The Romans would have been immediately routed, had not the invincible genius of Cæsar been there to sway and turn the tide of battle. After a hard-fought contest, the Nervian forces were almost annihilated; but the Nervii were not yet subdued. They are found, in 54 B.C., assisting the Eburones in the unsuccessful attack upon the camp of Quintus Cicero; and it was not until the following year that they finally submitted to the Romans. The Nervii possessed two important towns,—Bagacum (*Bavai*), their capital; and Camaracum (*Cambrai*).

NESS, LOCH, a lake of Scotland, in the county of Inverness, stretching from S.W. to N.E. for nearly 24 miles, with an average breadth of a mile and a quarter. It is fed by the River Oich, from Loch Oich, and by several other streams, of which the largest are the Moriston, the Foyers, and the Farigag. The depth of the loch near the centre is from 100 to 130 fathoms, its bottom being below the level of the sea; and owing to its great depth the water never freezes. The mountains on either side of the loch are lofty, rugged, and steep, rising to the height of 1200 or 1500 feet above the sea. The waters of the loch are conveyed to the sea by the River Ness, which falls into the Moray Firth at Inverness. Loch Ness is connected by the Caledonian Canal with Inverness on the N.E., and with Loch Oich on the S.W.

NESTON, GREAT, a town of England, county of Chester, near the shore of the estuary of the Dee, 11 miles N.W. of Chester. It has an ancient church with a handsome front and a tower; Methodist, Independent, Calvinist, and Roman Catholic churches; and several schools. The town depends chiefly for its prosperity on the summer visitors, who resort hither for the sake of the sea-bathing. Pop. (1851) 1524.

NESTORIUS, the founder of the sect of the Nestorians, *Nesotrius*. was born at Germanicia in Syria towards the close of the fourth century. After receiving his education in a convent, he was ordained a presbyter of Antioch. It was there that he imbibed the doctrine of the Syrian church, which held, in opposition to the Egyptian church, that the two natures of Christ were distinctly separate, and were united into one person by a certain relation. His simple and austere habits, his devotion to the cause of the church, and his fervid and winning eloquence, marked him out in no long time as a fit champion of the tenets he had adopted. An opportunity soon occurred for the exercise of his zeal and influence. In 428 he was promoted to the patriarchate of Constantinople. "Help me to subdue the heretics, and I will help you to subdue the Persians," was the fanatical boast by which he indicated to the emperor his intention of immediately commencing a vigorous course of proselytizing. Not content with persecuting the Arians, Novatians, and Quartodecimanians, he soon discovered in the current speech of the city an expression which savoured of the peculiar doctrine of the Egyptian church. That was the epithet "the Mother of God," a phrase which he alleged to imply the deification of the human nature of Christ, and which he therefore condemned. From this incident arose the famous Nestorian quarrels. The Constantinopolitan patriarch forthwith found himself engaged in hot controversy with several of his monks and clergy. They accused him of Photinianism; he accused them of Manicheism. They preached against him in the churches, and renounced their ecclesiastical allegiance; he turned them out of the churches, and deposed them. At this crisis, Cyril, the meddling and arrogant Patriarch of Alexandria, eager for an opportunity to bring down a powerful brother-bishop, insinuated himself into the contest, and changed it from a mere local squabble about a name of the Virgin Mary into a serious controversy touching the respective doctrines of the Syrian and Egyptian churches. After solemnly professing to be actuated solely by love for the true faith, and after employing the most gross deceits to maintain this profession, he organized a strong opposition against Nestorius, and at length, by artful flattery, he obtained from Pope Cœlestine I. the power of dealing with the alleged heresiarch. Convening a council at Alexandria in 430, the Egyptian patriarch launched twelve anathemas at the head of Nestorius. Nestorius hurled back twelve other anathemas. This rupture was fast growing into a schism, when the emperor, Theodosius II., anxious to restore the peace of the church, summoned the third œcumenical council to meet at Ephesus in 431. Nestorius repaired thither, trusting to the justice of his cause; but that, he soon found, was a frail offset against the shameless machinations and powerful influence of his adversary. He was summoned to the bar before his friends the Antiochian bishops had arrived; he was deposed on the charge of blasphemy before he had pled his cause; his appeal to the emperor was counteracted by misrepresentations; those who were favourable to him at court were overawed by a fanatical mob artfully raised by his indefatigable foes; and at length he was glad to escape from the ever-thickening broil by retiring to the cloister of Euprepus near Antioch. There the heresiarch enjoyed peace for four years. But by that time some of his former friends had taken up the cry against him, and, afraid lest he should communicate the taint of heresy to those around him, they resolved to cast him, like a pestilential carcass, beyond the pale of civilized society. He was accordingly banished to the Greater Oasis in Upper Egypt. But even in that solitary retreat no rest was to be found. He was soon obliged to flee before the invasions of the barbaric Blemmyes, and to take refuge in the Thebaid. Then the old man, at the command of the Roman governor of that district, was dragged about by a savage soldiery from one place to

Nestorius. another, until death closed his long career of troubles. The date of his demise is unknown.

Meanwhile, the favourers of Nestorius, or, as they were called, the *Nestorians*, were becoming numerous in the provinces of the East. The writings of the exiled patriarch, and of Theodore of Mopsuestia, translated into Syriac, were already circulating through Assyria and Persia, and making many converts. As early as 435 the celebrated school of Edessa had become the seminary of Nestorianism, and was sending forth numerous disciples zealous for the new doctrine. The most famous of these was Barsumas, the indefatigable and politic Bishop of Nisibis. In conjunction with Maanes, Bishop of Ardaschir, he prevailed upon the Persian king Pherozes to establish the Nestorians as the national church of Persia. A great stimulus was thus given to the sect. Patronized by the state, they made Seleucia the seat of their patriarch, and established an excellent seminary at Nisibis. Isolated from other Christians, and therefore forced to maintain a distinct and real individuality, they began to make their peculiar creed something more than a mere repudiation of the epithet "Mother of God." Accordingly, at a synod convened by the Patriarch Babæus at Seleucia in 496, a system of doctrine was framed and adopted. The characteristic dogmas of this system were, that in Christ there were two persons, the Divine Logos and the man Jesus; that these two persons were united together by no other connection than that of will and affection; that Christ, on that account, ought to be clearly distinguished from God; and that these tenets had not been derived from Nestorius, but had been held by the church from her infancy. Another peculiar opinion was, that it was lawful for bishops and presbyters to marry. Having thus obtained a constitution of its own, Nestorianism started on a long career of prosperity and activity. It was regarded with favour, or at least with toleration, under the Saracens, Arabs, and Tartars, the successive masters of Persia. Its missionaries travelled over all Northern Asia, and as far west as China, evangelizing the heathen, and planting numerous churches. At length, in 1551, it received a severe check, and its members were divided into two factions, by a dispute regarding the election of a patriarch. One party elected Sulaka, placed themselves under the jurisdiction of the Roman pontiff, and were afterwards known by the name of Chaldean Christians. The other party have continued till the present day to be the true representatives of the primitive Nestorian church in Persia. They are at present a simple, poor, illiterate, yet independent people, amounting to about 140,000, and living around Diz, the seat of their patriarchate, among the mountainous ranges of Kurdistan. Subjected for many ages to the proselytizing influence and persecution of Papists and Mohammedans, they have not escaped the infection of superstition. Their patriarch and their eighteen bishops are doomed to celibacy and perpetual abstinence from animal food; many fasts are observed; a peculiar religious festival in commemoration of the dead is held annually; and charms and talismans are often distributed by the clergy among their flocks. Yet their system of doctrine is free from all the more gross and deadly errors of the church of Rome. The Bible is recognised as the supreme and sole canon of faith; the inferior clergy are permitted to marry; and auricular confession, image-worship, and the belief in purgatory, are abjured. There is also a body of Nestorians existing in India, under the name of Syrian Christians, and acknowledging the jurisdiction of a patriarch. They amount to the number of 100,000 in Travancore, and are also numerous in the neighbourhood of that state. Although ignorant and superstitious, they are said to be essentially orthodox, and are on terms of friendly intercourse with the English prelates of India.

Several sermons, epistles, and fragmentary writings of

Nestorius, and other papers relating to the Nestorian quarrels, are published in the works of Marius Mercator by Baluze, 8vo, Paris, 1684. The most recent treatises on the subject are,—Perkins's *Eight Years' spent among the Nestorian Christians*, New York, 1843; Badger's *Nestorians and their Rituals*, in 2 vols. 8vo, London, 1852; and Marsden's *Christian Churches and Sects*, in 2 vols., London, 1856.

NESVISH, a town of European Russia, in the government of Minsk, on the Usha, 60 miles S.W. of Minsk. It is protected by fortifications, which, however, are in a very dilapidated state; and it has a Benedictine abbey. Pop. 4230.

NETHERLANDS. See HOLLAND.

NETSCHER, GASPAR, an eminent painter, was born, according to one account, at Heidelberg in 1639, but according to another, at Prague, in 1636. His father died when he was two years of age; and his widowed mother, fleeing from the dangers of a civil war, carried him to Arnheim. There the young orphan was adopted and educated by a benevolent physician named Tullekens. At first he was destined for the profession of his patron; but his great aptitude for painting soon caused the plan of his future career to be altered, and he was placed under an artist named De Koster. After a short time spent in painting birds and objects of still life, the pupil had exhausted all his master's instructions, and set out for Italy to complete his education there. Happening, however, to get married at Liège, and being compelled to practise his art for the support of his household, he could proceed no farther. He settled at Bordeaux, and toiled hard to earn a livelihood by painting fancy subjects. But those small cabinet pictures, which are now so highly valued on account of their exquisite finish, brought but a small remuneration; and after removing to the Hague, he turned his attention to portrait-painting. In this branch of his art he was more successful. His earnings soon became so considerable, that he was enabled at times to gratify his own taste and fancy by depicting musical and conversational pieces. It was in these that Netscher's genius was first fully displayed. The choice of the subjects, and the habit of introducing female figures, dressed in rich, glossy satins, were imitated from Terburg; but the easy yet delicate pencilling, the brilliant yet correct colouring, and the complete mastery over light and shade were all his own. He soon attracted notice, and was rapidly gaining both fame and wealth, when he was cut off at the premature age of forty-one. Many of Netscher's pictures may be found in the galleries of the Louvre, Hesse-Cassel, Berlin, Dresden, Munich, and Florence; at the Hermitage in St Petersburg, and in the English collections of Sir Robert Peel, Mr Hope, Lord Ashburton, and the Earl of Bridgewater. The style of Netscher was imitated by his two sons Theodore and Constantine; but these, though meritorious painters, were far inferior to their father.

NEU-BRANDENBURG, a town in the duchy of Mecklenburg-Strelitz, on the shore of Lake Tollen, 55 miles W.N.W. of Stettin. It is regularly built, and surrounded by walls, through which entrance is obtained by four gates. The principal buildings are the palace of the grand duke, a long, low building in the market-place; and the church of St Mary, a fine Gothic edifice, lately restored, which contains some good paintings. This town contains two other churches, several schools, a town-hall, and a theatre. It has manufactures of tobacco, paper, cards, leather, &c.; and carries on a considerable trade in these articles, and in horses and hides. An annual fair for wool is held here, and there are also horse races. Pop. 6145.

NEUBURG, a town of Bavaria, in the circle of Suabia, stands on the right bank of the Danube, 33 miles N.N.E. of Augsburg, and 45 N.N.W. of Munich. It is an old town, picturesquely situated on a wooded hill that rises from the river's side. Besides the town itself, which con-

Neuchâtel. sists of an old and a new part, and is partly walled, there are two suburbs. The ancient castle, formerly the residence of the dukes-palatine of Neuburg, is surrounded by a fine garden, and contains a collection of portraits, old armour, tapestry, &c. There are in the town three churches, a convent, a college (which formerly belonged to the Jesuits), several schools, a public library, museum, town-hall, barracks, arsenal, infirmary, and orphan hospital. Beer, brandy, earthenware, cloth, and saltpetre are the principal articles manufactured here; and fishing is also carried on to some extent. On an island in the river are the ruins of the ancient castle of Altenburg; and in the neighbourhood of the town are two residences of the King of Bavaria. The Danube is here crossed by two bridges, under which steamers pass by lowering their funnels. Pop. 6350.

NEUCHÂTEL, or **NEUFCHÂTEL** (Germ. *Neuenburg*), a canton of Switzerland, lying on the N.W. shore of the lake of the same name, between N. Lat. 46. 50. and 47. 10., and E. Long. 6. 25. and 7. 5. It is bounded on the N.E. and E. by the canton of Bern; S.E. by the Lake of Neuchâtel, which separates it from Fribourg and Vaud; S. by Vaud; W. and N.W. by France. Its length is about 30 miles, average breadth 11 miles; area 280 square miles. The surface of the canton is mountainous, being traversed through its whole length by the Jura Mountains. It consists of three different regions, distinct from each other in nature and appearance. The lowest part of the canton is that which extends along the shores of the lake, and is known by the name of Vignobles. This tract of country is for the most part planted with vines, and has an elevation of 1400 feet above the sea. The centre of the canton comprises a tract of land inclosed between two parallel ridges of the Jura, and is elevated from 2000 to 2400 feet above the sea. This region is known by the name of Vallon, and includes the Val de Travers and the Val de Ruz. Corn, pulse, grass, and fruits are grown here. That part of Neuchâtel which lies on the borders of France is called the Montagnes, and consists of the lofty ridges of the Jura and the high-lying valleys by which they are separated. These valleys are called La Chaux de Fond, Locle, La Chaux du Milieu, La Brevine, and La Sagne, respectively. The highest peak of the Jura within this canton is that of Chasseral, which has an elevation of 5285 feet. The canton contains numerous small streams, each of the valleys having at least one, to which it gives name; and, besides these, Neuchâtel is partly bounded by the Doubs on the French frontier, and by the Thielle, which joins the lakes of Bienne and Neuchâtel on the frontier of Bern. The climate of the different parts varies very considerably,—in the lower regions it is mild enough for the growth of the vine, but in the uplands it is very cold and bleak, the snow lying on some of the heights for seven or eight months in the year. The geological structure of the country is almost entirely calcareous, consisting of a kind of rock known by the name of Jura limestone. The only valuable mineral that is obtained in Neuchâtel is iron. The corn produced in the canton is not sufficient to supply the wants of the inhabitants, and a considerable amount has to be imported from the cantons of Bern and Basle. Potatoes are largely cultivated, even at great elevations among the mountains; and in the lower regions the cultivation of the vine is extensive, and the wines produced are highly esteemed. Of the whole surface of the canton, it has been calculated that about 42,700 acres are mountain pasture-land, 28,500 forests, 62,000 arable land, 37,000 meadows, and 2480 vineyards. The number of horned cattle in the canton in 1848 was 17,622; horses, 2589; sheep, 5113; goats, 2105; and swine, 4284. Bears and wolves, as well as deer and other kinds of game, are found in the forests; and the rivers and lakes abound in fish. The manufactures are of considerable importance; and among these that of watches occupies

the first place, and has contributed most effectively to the prosperity of the country. This branch of industry was first introduced here in 1665; and after it had been a century in operation, 12,000 gold and silver watches were annually produced. In 1848 the canton contained 9067 watchmakers, by whom upwards of 100,000 watches were yearly produced. The chief seats of this manufacture were the villages of Locle and Chaux de Fonds, in the bleak uplands of the Jura. The manufacture of lace is also carried on to a considerable extent, but it has declined considerably from its former importance. There were in 1848 only 1475 hands employed in this branch of industry, of which the chief seat is in the Val de Travers. Manufactures of linen, cotton, paper, &c., are also carried on. The trade of Neuchâtel is not very extensive, and consists principally in the export of the various articles manufactured here. The established religion is Protestant and Calvinistic, and this is professed by the majority of the people, the proportion of Protestants to Roman Catholics being nearly twelve to one. There are also a small number of Jews. The constitution of the canton is very anomalous; for though the King of Prussia claims the title of Prince of Neuchâtel, he has resigned all right of sovereignty over it; and the constitution, as established April 30, 1848, is entirely republican. The legislative body consists of 80 members, chosen by the people, one for every 500 inhabitants. Their term of office is for six years, and one-third of the number go out every two years. The executive power is confided to a council of seven, chosen by the members of the legislature, and presiding each over one of the seven departments of the canton. Neuchâtel sends four members to the National Council of Switzerland, and two members to the Council of States. The canton of Neuchâtel was formerly a part of the German empire, but afterwards was bestowed on the House of Châlons, with the title of Count of Neuchâtel. These counts were subject to the feudal rights of the princes of Orange. In 1398 Neuchâtel was admitted into the Swiss Confederation; and in 1579 the county of Valendis having been joined to that of Neuchâtel, the title of Count was exchanged for that of Prince of Neuchâtel. The line of Châlons having become extinct, it passed to William III. of Great Britain as Prince of Orange; and on his death in 1702, his nephew Frederic I. of Prussia took possession of the principality. In 1805 it was ceded by the treaty of Tilsit to France, and given by Napoleon to Marshal Berthier; but it was restored to Prussia in 1814, though still recognised as holding the twenty-first place in the Swiss confederacy. After this it continued under the government of Prussia, and a constitution was granted by Frederick William III.; but in 1848 this state of things came to an end; a republican constitution was established; and since that time the authority of the King of Prussia has been merely nominal. On the 2d of September 1856 an attempt was made by a party of royalists to re-establish the authority of the Prussian monarch in Neuchâtel; but this proved unsuccessful, and they were taken prisoners, and arraigned for high treason. The Prussian ambassador demanded that the prisoners should be released, and the rights of Prussia recognised. This demand was rejected by the Swiss government, and the King of Prussia refused to enter into any negotiations about the canton of Neuchâtel until the prisoners were released. At last it was settled by a treaty at Paris, May 26th 1857, that an amnesty should be granted to the insurgents of Neuchâtel, and that the King of Prussia should resign all claim of sovereignty over the canton, reserving only the right to bear the title of Prince of Neuchâtel. Pop. (1850) 70,753.

NEUCHÂTEL, the capital of the above canton, stands at the mouth of the Seyon, partly on the level ground on the shore of the lake, and partly on the slope of the

Neuchâtel.
||
Neuhoff.

Jura Mountains. It is well built, and contains several handsome streets, some of which stand on the alluvial ground gained from the lake. The castle, which is situated on an eminence, is an ancient building of some size, and was formerly the residence of the princes of Neuchâtel, but is now occupied by the government offices. Near the castle stands the church, a Gothic edifice of the twelfth century, with some parts of still more ancient date. The town-hall, a handsome building in the Grecian style, stands in the lower part of the town. The town contains also a public school, with a museum of natural history, a ladies' school, and two hospitals. A considerable trade is carried on through Neuchâtel in the manufactures and agricultural produce of the canton. Pop. (1850) 7727.

NEUCHÂTEL, *Lake*, forms the S.E. boundary of the canton of the same name, and is about 24 miles in length by 4 in breadth. The surface is 1320 feet above the sea, and the greatest depth is 400 feet. It is fed by the Orbe from the S.W., by the rivers of Neuchâtel from the N.W., and by the Broye from Lake Morat; and it discharges its waters by the Thielle into the Lake of Bienné, and thence into the Aar. The scenery of the lake is fine, but inferior in grandeur to that of some of the other Swiss lakes. A considerable trade is carried on on this lake; and it is navigated by a steamer, which touches at the principal places on its banks.

NEUDORF (Hungarian, *Iglo*), a town of Hungary, county of Zips, in a beautiful plain on the Hernad, 5 miles S. by W. of Leutschau, and 136 N.E. of Pesth. It is well built, and has one principal street and square. The parish church is a fine building with a lofty tower. There are also a Protestant church, a high school, court-house, town-hall, theatre, and hospital. The manufacture of linen and paper, and the forging of iron, are carried on here; and iron and copper mines are worked, and flax cultivated, in the vicinity. Pop. 5900.

NEUHAUS, a town of Bohemia, circle of Tabor, stands on the Nezarka, 26 miles N.E. of Budweis. It has an old castle, now in ruins, a handsome parish church, five other churches, a Franciscan convent, town-hall, barracks, and theatre. Manufactures of linen, cotton, and woollen fabrics are carried on. Pop. 7604.

NEUHAUSEL, a market-town of Hungary, in the county of Neutra, on the river, and 22 miles S.S.E. of the town of that name. It was formerly a fortress of some importance; and has a church, a Franciscan monastery, two schools, and a town-hall. Some trade is carried on in corn, wine, and cattle. Pop. 6780.

NEUHOF, THEODOR, BARON VON, a noted military adventurer, was descended from a noble Westphalian family, and was born at Metz toward the close of the seventeenth century. His father, an officer in the French service, died when he was still young, and left him exposed to the attacks of poverty and the freaks of fortune. He obtained a lieutenancy in the regiment of Alsace; but a habit of falling into debt, and of never getting out of it, did not suffer him to remain long at this post. He then shifted about from one country to another, trusting to his titles, address, and good luck for a livelihood. At length he seemed to have gained a permanent footing in Spain. The two famous statesmen Alberoni and Ripperda patronized him in succession; a colonel's commission was conferred upon him; and a lady of honour to the Spanish queen gave him her hand in marriage. But no sooner did the German fortune-hunter find that his wife's dowry fell far short of his expectations, than he seized upon her jewels, bade adieu to the land of his adoption, and escaped over the border into France. His plunder was soon squandered, and his favourite character of wandering impostor was resumed. For several years he continued to skulk from one European city to another, changing his name to suit his circumstances,

and fleeing from old debts only to fall into new ones. At last fortune began to smile upon him once more. Happening, in the course of his wanderings, to meet some of those Corsican patriots who were then asserting their country's independence against the Genoese, he commenced, with his usual ready hypocrisy, to profess a deep interest in their cause, and to proffer his counsel. He advised them to elect some noble and influential personage for their king, who should lead their armies, form their government, and lay the foundation of their independence; and he hinted that he, a German baron, and a favourite with the princes of Europe, was a suitable object for their choice. The hint was taken; and the Corsicans agreed to support his ambitious scheme, on condition that he should furnish some substantial proof of his devotion to their cause. Neuhoff was immediately on foot, using all his arts and address to obtain assistance from several European courts for the patriotic Corsicans. His efforts were unsuccessful. He then posted to Africa, and by dint of enormous promises, received a ship-load of supplies and ammunition from the Dey of Tunis. With these he landed at Corsica in March 1736, and was received with enthusiasm by the islanders. The game of ambition thus successfully begun was now played out with consummate tact and dexterity. He kept up a show of possessing great wealth; added to his name the honourable titles of most of the courts in Christendom; feigned to be constantly receiving despatches from the principal powers of Europe and Africa; and at length declared himself a candidate for the crown, and obtained it in the following April. The same system of display which had raised the foreign adventurer to the throne was now found necessary to keep him there. Accordingly, he surrounded himself with 400 body-guards, distributed among his followers many brevets of nobility, instituted a new order of knighthood under the name of the Order of Deliverance, and asserted his sovereign power and majesty by hanging up three persons of high birth. But these arts, though successful at first, could not long defend the impostor against the disclosures of advancing time. The great promises he had held out of foreign assistance continued to be unfulfilled; rumours concerning his real character began to reach the island; and the failure of his attempt to take the town of Bastia from the Genoese proved his incapacity to vindicate the freedom of his new subjects. His popularity was waning fast when, at the end of a reign of eight months, he entrusted the government to a council of regency, and repaired to Europe to procure the reinforcements which he had promised. Here ended the reign of Theodore I. of Corsica. Happening, in his vain search for supplies, to repair to Amsterdam, he was pounced upon by some of his old creditors, and was cast into prison. When by mortgaging two of the Corsican towns to a Jewish merchant, he had received a large sum of money, and had been enabled in 1738 to release himself from prison, and to repair to Corsica with three merchant vessels and a frigate, he found that the island was entirely under the power of the French, the allies of the Genoese, and that the islanders were unable to receive him. Affairs were not more favourable, even after the French had departed in 1741. On presenting himself once more before his subjects in 1742, Neuhoff found that there was a strong faction of the Corsicans against him, and that the Genoese had set a price upon his head. He immediately abandoned his forlorn hopes, and fled to England. The reverses, however, of this poor puppet of fortune were not yet at an end. His Dutch creditors soon ferreted him out, and for seven years he lay in the King's Bench Prison. Through the interference of Horace Walpole, he obtained his release in 1756, under the act of insolvency, and was enabled to make an agreement with his creditors by mortgaging Corsica. But grief and poverty brought his life to a close in December of the same year.

Neuhoff.

Neuilly-
sur-Seine
||
Neuss.

NEUILLY-SUR-SEINE, a town of France, department of Seine, on the right bank of that river, about $1\frac{1}{2}$ mile N.W. of Paris, on the road to St Germain. Here are the ruins of the palace of Neuilly, which was a favourite residence of Louis Philippe, but which was destroyed in 1848. The park of Neuilly, which extends for some distance down the river, is a favourite holiday resort of the Parisians. The river is here crossed by a handsome bridge of five arches, each 120 feet wide. Manufactures of porcelain, starch, and chemical substances are carried on. Pop. 15,897.

NEUMARKT, a town of Prussia, in the government of Breslau, 16 miles W.N.W. of the town of that name. It has Protestant and Roman Catholic churches, and several courts of law. Manufactures of tobacco, tiles, woollen and linen stuffs, and paper, are carried on here; and there is a market for corn. Pop. 4320.

NEUMÜNSTER, a town of Denmark, in the duchy of Holstein, 17 miles S.S.W. of Kiel. It is large and well built, and has a church in the Italian style of architecture. The manufactures are considerable, consisting principally of cloth and metal buttons. Pop. 4700.

NEUSATZ (Hung. *Új-Videk*), a town of Hungary, county of Bacs, on the left bank of the Danube, opposite to Peterwardein, and 46 miles N.W. of Belgrade. It is surrounded by walls; and has several Greek, Roman Catholic, and Armenian churches; a synagogue; and several schools. A considerable trade is carried on here, for which the position of the town on the Danube, and not far from the Drave, the Save, and the Theiss, gives it great advantages. The Danube is here crossed by a bridge of boats. Commercial intercourse is carried on through Neusatz between Vienna, Leipsic, &c., on the one hand, and Salonika and other Turkish ports on the other. Pop. 19,700.

NEUSIEDL, LAKE OF (Hung. *Fertő Tava*), a lake of Hungary, extends between the counties of Cedenburg and Weiselburg. It is about 23 miles in length and 7 in breadth, and varies from 9 to 13 feet in depth; area about 120 square miles. Its waters are not potable, from containing much sulphate of soda, with some muriate of soda and carbonate of soda. (See Bright's *Travels in Hungary*.) It is fed by the River Vulka. The principal towns on its shores are Ruth and Neusiedl.

NEUSOHL, or **BESZTERCZEBANYA**, a town of Hungary, capital of the county of Sohl, in the territory of Presburg, is situated on the right bank of the Gran, about 80 miles N. of Buda. It is pretty well built, and has wide streets, and a market-place near the centre. It contains the ruins of an old castle; several churches, one of which has a bell weighing upwards of 5 tons; an episcopal palace; Roman Catholic and Protestant schools; a theatre; court-house; and infirmary. Neusohl is situated in the middle of a mining district, whence copper, gold, silver, iron, &c., are obtained; and the annual produce of the mines of Herengrund, which are at some distance from the town, amounts to 100 tons of copper and 400 lb. of silver. Neusohl contains one of the largest smelting houses in Hungary; and the manufacture of sword-blades, cloth, leather, paper, earthenware, sugar, &c., is carried on here. Pop. 6500; but including the suburbs, upwards of 10,000.

NEUSS, a town of Prussia, in the province of Düsseldorf, near the union of the Erft and the Rhine, 21 miles N.W. of Cologne. It is surrounded by walls, and protected by towers and ditches. The principal building is the church of St Quirinus, which was built in the thirteenth century, and exhibits a curious specimen of the transition from the round to the pointed style in architecture. The town has also two other churches, a synagogue, a school, a lunatic asylum, orphan's hospital, &c. Manufactures of cotton and woollen cloth are carried on here; and there is a considerable trade, especially in corn, for which Neuss is the principal market in Rhenish Prussia. This town, under the

name of *Novesium*, was founded by the Romans under Drusus, and is frequently mentioned by Tacitus. Pop. 9567.

NEUSTADT (Polish, *Prudnitz*), a town of Prussia, in the province of Silesia, on the Prudnitz, 29 miles S.W. of Oppeln, and 18 S.E. of Neisse. It is well built, and contains Roman Catholic and Protestant churches, a convent, synagogue, two hospitals, courts of law, and a penitentiary. The manufactures consist of cloth, leather, paper, tiles, &c. Pop. 6797.

NEUSTADT, or *Wiener-Neustadt*, a town of Austria, 26 miles S. of Vienna. It is built with some regularity, in the form of a square, and surrounded by fortifications. The streets are broad and well paved. The ancient castle, which is now used as a military academy for the education of officers for the Austrian army, is a square building with a tower; and in the chapel attached to it the Emperor Maximilian I. is buried. This academy, the only one of the kind in the empire, is attended by 468 pupils, who receive their appointments, some from the emperor, and some from the provincial estates. Many of the public buildings of Neustadt were destroyed by a dreadful fire in 1834, which laid nearly the whole of the town in ashes. There is here a Cistercian convent, which has a museum and a library of 20,000 volumes. The manufactures are considerable, consisting of silk and velvet cloth, paper, porcelain, &c.; and an active transit trade in wine, hardware, leather, sugar, &c., is carried on. Neustadt, which is as old as the twelfth century, has obtained, on account of its constant fidelity to the Austrian princes, the designation of "Ever Faithful." Pop. 12,346.

NEUSTADT-AN-DER-HAARDT, a town of Bavaria, circle of Palatinate, on the Spirebach, 14 miles W. of Spire, and 16 E.S.E. of Kaiserslautern. The principal church is a building of the tenth century, and contains monuments of many of the electors and counts palatine. There are also to be seen here the remains of an old castle, to which the town probably owed its origin. Neustadt has a court of law, a school, and an hospital. Its manufactures are cloth, paper, chemical substances, gunpowder, &c. Some trade is carried on in wine and timber. Pop. 6088.

NEUSTADT-AN-DER-ORLA, a town of Saxe-Weimar, capital of a circle of the same name, 24 miles S.E. of Weimar. It has an ancient castle, two churches, a savings-bank, and an hospital. Manufactures of cloth, leather, &c., are carried on; and there is some trade in books. Pop. 4250.

NEUSTADT-EBERSWALDE, a town of Prussia, in the province of Brandenburg, on the Schwartz, 28 miles N.E. of Berlin. It is surrounded by walls, and consists of three parts, an upper and lower town, and a suburb. It has mineral baths; and manufactures of hardware, cloth, earthenware, &c. There is some trade in manufactured goods, and also in wool and cattle. Pop. 5581.

NEUSTADTL-AN-DER-WAAG, or **VAGH-UJHELY**, a town of Hungary, county of Neutra, on the Waag, 52 miles N.N.E. of Presburg. The cultivation of the vine is largely carried on here; and there is a considerable trade in corn, wool, &c. Pop. 5500.

NEU-STRELITZ, the capital of the grand duchy of Mecklenburg-Strelitz, is situated on Lake Zierker, 57 miles N. of Berlin. It is regularly built, in the form of an octagon, has several handsome streets and squares, and is surrounded by walls and fortifications. The palace of the grand duke is a building partly in the Grecian, partly in the Italian style, and contains an extensive library and a collection of antiquities. In the town there are various churches, a college, several hospitals, schools, a theatre, &c. Most of the inhabitants find employment in connection with the court or the army; but some are engaged in the manufacture of beer, soap, tobacco, &c. Neu-Strelitz is the seat of the legislature and of the supreme courts of law, as well as of the government of the duchy. It was

Neustadt
||
Neu-
Strelitz.

Neutrit-
chein
||
Neutrality.

founded by Adolph Frederic, who fixed upon this as his residence, after the destruction by fire, in 1712, of the former palace at Alt-Strelitz, some miles distant. The town thus rose up round the new palace; but the intention of their founder to connect by buildings the old and new towns has not been carried into effect. Pop. 6484.

NEUTITSCH, or NOWY-GYGIN, a town of Austria, in Moravia, stands on the Titsch, 26 miles E. of Olmütz. It is well built; and has an old castle, three churches (one of which is ancient, and in the Byzantine style), a town-hall, and several schools and hospitals. The inhabitants are principally employed in the manufacture of woollen stuffs, in which some trade is carried on. Pop. 9000.

NEUTRA, or NYITRA, a town of Hungary, capital of a county of the same name, stands on the River Neutra, about 50 miles E.N.E. of Presburg, and 70 N.W. of Buda. It has a castle, which stands on an eminence, and contains within its precincts a cathedral, an episcopal palace, and a county-hall. Neutra has also a theological seminary, a high school, an inferior school, and a charity school belonging to the order of the Piarists. The inhabitants are chiefly employed in agriculture, but partly also in weaving; and an active trade is carried on in the wines of the adjacent country. Pop. 4490.

Definition. NEUTRALITY (Fr. *Neutralité*), in politics is the term employed to indicate the state of those nations who, when a war is being carried on, take no part in the contest, and evince no peculiar friendship for, or hostility to, any of the belligerent powers.

Neutrality in general. Many volumes have been written in regard to the rights and duties of neutral nations. But it is easy to see that these cannot be exactly defined; that, with the exception of a few leading principles, they are necessarily subject to much alteration; and that a line of conduct which a neutral power might very properly follow at one time and under one set of circumstances, might be very improper at another time and under a different set of circumstances. This arises from the fact, that the rights and duties of neutrals are not absolute, but relative only. They are in all cases affected by, and mixed up with, the rights of belligerents. And as the latter vary with the varying nature of different contests, so must the former, or the rights of neutrals.

In general it may be laid down that it is the duty of neutrals to conduct themselves in a spirit of perfect impartiality, and to do nothing that can be fairly considered as being peculiarly favourable or hostile to either of the parties engaged in hostilities. And this is about the only principle that can be said to be universally applicable to neutrals.

We do not mean, in the few remarks we have to offer on this subject, to enter into any inquiries with regard to the conduct of neutrals on land. The questions to which such conduct may give rise are for the most part easy of solution, and have comparatively little interest. But it is otherwise with those questions which arise out of the proceedings of neutrals at sea. These give birth to questions in regard to which there is much diversity of opinion; and which, from our being a great maritime power and their direct bearing on our interests, have always been justly looked upon in this country as of paramount importance.

Articles
contraband
of war.

I. When two nations are engaged in war, if there be any foreign article or articles necessary for the defence or subsistence of either of them, and without which it would be difficult for it to carry on the contest, the other may legitimately exert every means in its power to prevent its opponent being supplied with such article or articles. All writers of authority on international law admit this principle; and lay it down, that a nation which should furnish a belligerent with articles *contraband of war*—that is, with supplies of

warlike stores, or of any article required for the prosecution of the war—would forfeit her neutral character, and that the other belligerent would be warranted in preventing such succours from being sent, and confiscating them as lawful prize. And besides being consistent with the most obvious principles, approved by jurists, and enforced in every contest, this doctrine has been sanctioned by repeated treaties. The only difficulty, indeed, that has ever arisen in regard to this matter has been with respect to the articles which should be reckoned contraband of war; and in the view of obviating such difficulty, these articles have sometimes been specified in treaties and conventions. (See the references in *Lampredi del Commercio de' Popoli Neutrali*, § 9.) But this classification has not always been respected during hostilities. And it is sufficiently evident that an article which may not be contraband at one time, or under certain circumstances, may become contraband at another time, or under different circumstances. It is admitted on all hands, even by Hubner, the great advocate for the freedom of neutral commerce,¹ that everything that may be made *directly available* for hostile purposes is contraband, as arms, ammunition, horses, timber for ship-building, and all sorts of naval stores. The greatest difficulty has occurred in deciding as to provisions (*munitions de bouche*), which have sometimes been held to be contraband, and sometimes not. Lord Stowell has shown that the *character of the port* to which the provisions are destined, is a principal circumstance to be attended to in deciding whether they are to be looked upon as contraband. A cargo of provisions intended for an enemy's port, in which it was known that a warlike armament was in preparation, would be liable to arrest and confiscation; while, if the same cargo were intended for a port where none but merchantmen were fitted out, the most that could be done, according to his lordship, would be to detain it, paying the neutral the same price for it he would have got from the enemy.

By the ancient law of Europe, a ship conveying any contraband article was liable to confiscation as well as the article. But in the modern practice of the courts of admiralty of this and other countries, a milder rule has been adopted, and the carriage of contraband articles is attended only with the loss of freight and expenses, unless when the ship belongs to the owner of the contraband cargo, or when the simple misconduct of conveying such cargo has been connected with other malignant and aggravating circumstances. Of these, a false destination and false papers are justly held to be the worst.

It appears pretty evident that the principle on which the doctrine of goods contraband of war has been established may justify, or rather require, its extension to various important articles not hitherto or usually reckoned as contraband. The rights of belligerents to hinder neutrals from supplying their enemies with articles necessary to enable them to carry on the contest, is alike clear and undoubted. But a foreign article, indispensable or highly useful to a nation engaged in war, may not be of the class called *munitions de guerre*, and may not be directly available in the prosecution of hostilities. That, however, is really immaterial. It is enough to warrant the prevention of its importation, that without it the importers would be unable to continue the contest, or that the inconveniences resulting from the want of it would be so very considerable as to dispose them to sue for peace, or to accept reasonable terms if offered. The distinctive peculiarity of articles declared to be contraband of war is not that they belong to one class of products or another, but that the want of them would inflict serious injury on the party by whom they are imported.

Considered in this, its true light, the term "contraband of war" becomes of the highest importance; and there are

¹ *Le la Suisse des Bâtimens Neutres*, tom. i., p. 193.

Neutrality. but few products which may not be fairly brought, at one period or another, within the list of contraband articles. Thus, supposing that we had the misfortune to be engaged in a contest either with a single power or a combination of powers which had means to intercept, cut off, or materially obstruct our supplies of corn, cotton, and tea: can any one doubt that our enemies would be justified, or that they would hesitate, in availing themselves of so powerful a means of annoyance? Neutrals might join us in protesting against such a proceeding, on the ground that the articles referred to had not hitherto been reckoned contraband of war, and they might also allege that their trade would be seriously prejudiced by so unusual and so illegal a proceeding. But these representations, supposing them to be made, would not go for much. Our enemies would say, that in defining contraband of war, everything depended on circumstances; and that as the want of the articles referred to would lay us under very considerable difficulties, they were, from that very circumstance, properly included in the prohibited list. They would no doubt express at the same time their regret that this conduct of theirs should be productive of injury or inconvenience to neutrals. That was not its purpose. They had resorted to it in the exercise of their undoubted rights as belligerents;¹ and it was only indirectly and by accident that it affected neutrals. When great nations are at war, such contingencies can seldom be avoided; and when they occur, they should be ascribed to the necessity of the case, and afford no reasonable ground of complaint.

Nations engaged in hostilities may not always have acted on these principles; but if so, it will be found that their forbearance was not dictated by a want of right or of will, but of power. Supposing that we were unhappily again engaged in a struggle with France, we could not employ our navy in any way more likely to accelerate the return of peace than in preventing the importation of cotton, colonial produce, and naval stores, into that country; and the exportation of her silks, wines, and other products. This would be a very likely way to distress our enemy; and the more he is distressed, the sooner will the struggle terminate.

In the following Declaration in regard to maritime law, signed by the principal European powers in 1856, the disputes to which its uncertainty has led are justly deplored:—

Declaration of 1856 in regard to maritime law. "*Declaration respecting Maritime Law, signed by the Plenipotentiaries of Great Britain, Austria, France, Prussia, Russia, Sardinia, and Turkey, assembled in Congress at Paris, April 16, 1856.*"

"The Plenipotentiaries who signed the Treaty of Paris of the 30th of March 1856, assembled in Conference,—

"Considering:

"That maritime law, in time of war, has long been the subject of deplorable disputes;

"That the uncertainty of the law, and of the duties in such a matter, gives rise to differences of opinion between neutrals and belligerents which may occasion serious difficulties, and even conflicts;

"That it is consequently advantageous to establish a uniform doctrine on so important a point;

"That the Plenipotentiaries assembled in Congress at Paris cannot better respond to the intentions by which their Governments are animated, than by seeking to introduce

into international relations fixed principles in this re-Neutrality. spect;

"The above-mentioned Plenipotentiaries, being duly authorized, resolved to concert among themselves as to the means of attaining this object; and, having come to an agreement, have adopted the following solemn Declaration:—

"1. Privateering is, and remains, abolished;

"2. The neutral flag covers enemy's goods, with the exception of contraband of war;

"3. Neutral goods, with the exception of contraband of war, are not liable to capture under enemy's flag;

"4. Blockades, in order to be binding, must be effective, that is to say, maintained by a force sufficient really to prevent access to the coast of the enemy.

"The Governments of the undersigned Plenipotentiaries engage to bring the present Declaration to the knowledge of the States which have not taken part in the Congress of Paris, and to invite them to accede to it.

"Convinced that the maxims which they now proclaim cannot but be received with gratitude by the whole world, the undersigned Plenipotentiaries doubt not that the efforts of their Governments to obtain the general adoption thereof will be crowned with full success.

"The present Declaration is not and shall not be binding, except between those Powers who have acceded, or shall accede, to it.

"Done at Paris, the 16th April, 1856.

(Signed)

"BUOL-SCHAUENSTEIN.

"WALEWSKI.

"CLARENDON, &c."

But the "uncertainty" complained of in the above Declaration is not of a kind that can be got rid of. It is inherent in the subject. Maritime laws of the class now under consideration do not rest on any fixed or immutable principles. They necessarily vary with the varying condition and exigencies of society. And those rules and regulations that may in the estimation of one country appear to be alike just and expedient, may in that of another be held, on quite as good grounds, to have exactly the opposite qualities. The above Declaration expressly excepts articles contraband of war from the privileges conceded to goods on board neutral ships; but it does not specify the articles which are to be considered contraband. And it was quite as well that this vexed, or rather insoluble question was left open; for it is most probable that the plenipotentiaries who subscribed the Declaration would not have agreed on any definition. And supposing they had subjoined a list of contraband articles to the Declaration, it would very speedily have ceased to be of any weight. Whether an article should or should not be deemed to be contraband depends on circumstances which it is impossible to foresee or appreciate beforehand. And such being the case, it is futile to attempt to prevent further disputes by making out lists of contraband articles. We have seen that this has been frequently attempted, and it has as frequently failed. Such lists may be respected for a while; but as soon as any contracting party or great power conceives that it would be for her interest or advantage to exclude some articles from, and to include others in, the list, there is an end of its influence and authority.

¹ Une puissance belligérante ne peut voir avec indifférence que son ennemi se renforce par des marchandises qui servent directement et indubitablement à faire la guerre; et elle ne blesse pas le droit des gens si elle empêche que ses marchandises ne parviennent à l'ennemi en les détenant, soit pour en payer la valeur au propriétaire, soit pour les restituer quand le danger sera passé. On peut même imaginer des cas, où les circonstances extraordinaires justifiaient une telle détention à l'égard des marchandises, qui ne servent pas exclusivement à l'usage de la guerre, et sur lesquelles elle ne peut dans la règle s'arroger aucune disposition. (Martens, *Précis du Droit Public*, lib. viii., cap. 7, § 315.) Heineccius says, "Dans une guerre il ne s'agit pas même de demander s'il peut-être permis à quelqu'un de porter à notre ennemi ce qui peut lui être nécessaire puisque nous avons le droit de prendre les armes contre quiconque s'opposerait à notre défense ou la rendrait difficile ou incertaine." (Quoted by Lampredi, p. 47, Paris 1802—see also Vattel, book iii., cap. 7, § 113, and a host of other authorities.)

Neutrality.

The principle that free ships make free goods, or that the flag covers the cargo (*que le pavillon couvre la marchandise*), and that consequently enemies' goods, not contraband of war, may be safely conveyed in neutral bottoms, after being long resisted by this and most other maritime states, has been assented to in the Declaration referred to. In judging of the wisdom of this concession, everything depends on the interpretation of the phrase "contraband of war." If it were restricted, as has usually been the case, to warlike stores (*munitions de guerre*), or articles directly available for warlike purposes, it would be in many respects justly censurable. For it is plain, that under the limitation now supposed, the trade of a belligerent power, with its colonies or other countries beyond sea, might be prosecuted in neutral ships nearly to the same extent, and with as much security, during war as during peace. But it is not easy to imagine that a principle having such consequences should be acted upon by any power having a preponderating naval force, in the event of her engaging in hostilities. Such power must then do one of two things: she must either consent to relinquish some of the most important advantages to be derived from her naval ascendancy, or she must reject the principle in question. And there is little doubt that she would adopt the latter alternative; and she might do this directly, by resorting to her natural and indefeasible right to seize enemies' goods wherever they are to be met with; or indirectly, by extending the list of contraband articles, so as to make it include all those of any importance carried by sea into or from the enemy's ports. Either way would answer the purpose; and we may be pretty well assured, that under the supposed circumstances one or other of them would be followed.

Blockade, influence of.

II. But it may perhaps be said, that though the right to carry enemies' goods not contraband of war be conceded to neutrals by the Declaration of Paris, that right is restricted and confined within proper limits by the maintenance of the system of blockade. But we take leave to doubt whether this restriction be good for much. It is distinctly laid down in the Declaration, that to be binding or legal, a blockade must be effective; that is, it must be "maintained by a force sufficient really to prevent access to the coast of the enemy." But though the blockade of one or of a few ports may perhaps be made effective, it is abundantly certain that no such blockade can ever be made to apply to an extensive coast. Though our navy were doubled or trebled, it would not suffice to make an effective blockade of the coasts of France, of Spain, or of the United States. And why should a country with a powerful naval force bind herself beforehand to employ it only in one way? Why not employ it in any way, whatever it may be, which happens to be at the time most conducive to the ends she has in view?

But supposing that an impossibility may be realized, or that an extensive coast may be effectually blockaded, the circumstance would be of much less consequence now than formerly, or than is generally imagined. Suppose, for example, that we are at war with France, and that we effectively blockade every portion of her coast, whether on the ocean or the Mediterranean: the result would be, that the over-sea produce suitable to her wants would be imported into the contiguous ports of Belgium, Spain, and Piedmont, and that it would be carried from them by railways and otherwise to every part of France.

It is plain, therefore, that these are not matters in which much dependence can be placed on the resource of blockades. These may be advantageously resorted to when the object is to reduce a town, to obstruct the trade of a port or a river, to prevent the sailing of a squadron, and so forth; but as measures directed against the trade of any great country, they must be nearly, if not wholly, impotent. In the case of France, it is quite clear that the strictest possible blockade could not inflict half the injury on her that its

maintenance would entail upon ourselves. If the trade of neutrals in war is to be influenced by nothing but effective blockades, it may be held to be practically free from all obstruction. But it cannot be supposed that when the evil day comes it will be so dealt with. When the existence of nations are at stake, they will not be withheld by declarations like the above from availing themselves of every means by which they may hope either to promote their own security or to injure their enemies.

Neutrality.

III. It is further obvious, were the rules laid down in the Declaration of 1856 to be carried into effect without large additions being made to the list of contraband articles, that neutrals would engross almost the entire over-sea trade of countries engaged in war. Comparatively few of the articles which we export come under the description of warlike stores; and supposing we were to be engaged in hostilities, neutral ships which did not take on board contraband articles would navigate with perfect security, while our ships would be exposed to the risk of capture. The magnitude of this risk would depend on various contingencies, and would be measured by the higher premium of insurance that would have to be paid on them and on articles embarked in them. But considering the close competition to which our shipowners are already exposed, the additional premium they would have to pay, even though it were not very considerable, would most probably turn the scale in favour of the neutrals; and if they were once introduced and employed for any considerable period, it might not be an easy matter for our ship-owners to regain the ground they had lost, or to recover their former position, on hostilities being terminated. But in whatever way it may be defeated or eluded, it is not to be supposed that we should abide, in periods of war and difficulty, by a rule that would tie up our hands and consign the entire over-sea trade of the empire to foreigners. This would be a degree of liberality to which we can hardly be expected ever to arrive, and which, were it realized, would be more injurious to our best interests than the most intense selfishness.

Influence of the new system over the trade of belligerents.

IV. Some of the more recent opponents of the old system of maritime law do not deny these statements. But they allege that they are founded on false principles. Private property, say they, is now respected in all contests carried on by land; and it would be for the advantage of all nations, whether belligerent or neutral, were the same war. In a humane and generous policy extended to private property at sea. But this sort of reasoning is more specious than solid. On a little examination it will be found that the cases have no real analogy. Private property on land, and the treasures of art and learning, are respected so far, that they are sometimes unconditionally, but frequently also on the payment of a contribution or ransom, exempted from injury. This is done because experience has shown that, while the destruction of the articles referred to may be productive of much misery and loss, it has little or no influence over the decision of the contest. But we are not hence to infer that the destruction of private property at sea will be equally ineffectual. In our unfortunate contest with the United States in 1814, the destruction of the Capitol at Washington was an act disgraceful to our arms, and which had no effect except to inflame the hostile feelings of the Americans. But the severe check which the contest gave to the trade of the Union made the citizens generally averse to the war; and was, indeed, the main cause of its being so speedily terminated. No such result could, however, have happened had American merchant ships been exempted from capture or molestation.

Project for exempting private property at sea from attack during war. Inconspicuous of such project.

Suppose we are at war, and that our enemy, having succeeded in landing a force in some part of the kingdom, such as Kent or Connaught, inflicts on the peasantry out-

Neutrality. rages similar to those which the troops of Louis XIV. inflicted on the defenceless inhabitants of the Palatinate; such proceedings, by not sensibly affecting either our wealth or the sources of our power, would in no wise accelerate the termination of hostilities. On the contrary, they would tend to their prolongation, by inspiring us with a strong desire to avenge such wanton and unnecessary cruelty. But it would be quite another matter were our enemy able seriously to obstruct our trade, to prevent our exports, or to sink, burn and destroy the ships that were conveying to us supplies of necessary articles. Such proceedings might lay us under the greatest difficulties, and would be the most likely means to make us listen to proposals for an accommodation.

Everybody knows that the unpopularity of the French rule in Germany and other parts of the Continent, in the latter part of the war against Napoleon, was in great measure occasioned by the destruction of their trade, which, on the one hand, rendered their corn and other disposable produce a mere drug, while, on the other, it added enormously to the prices of cotton, sugar, coffee, and most foreign articles. But had the rules and regulations embodied in the Declaration of 1856 been then in force, no such result would have happened. We should have had the singular combination of maritime peace and territorial war. And the trade of Prussia, Holland, and the other countries subject to France, and, indeed, of France herself, would have been as securely and cheaply carried on in neutral bottoms as it would have been in a period of universal tranquillity. Nothing, therefore, can be more contradictory and illogical than to contend that we are bound to extend the same immunity during war to private property at sea that is extended to private property on land. The cases are in no degree parallel. In the one, private property is respected because its destruction is seldom injurious except to the individuals immediately interested, and has little or no general influence; in the other case, private property is seized or destroyed because those from whom it is taken, being the carriers or purveyors of necessary articles for the community, their loss must seriously affect the latter, and may reduce them to the greatest straits.

Abolition
of priva-
teering.

V. The abolition of privateering by the Declaration of Paris is of the highest importance, and should give general satisfaction. This practice appears to be a remnant of that system of private war which is universally waged by individuals in early or barbarous ages, but which gradually disappears as society advances. Privateers rarely attack ships of war. They do not act in concert, or with any object in view other than their own private gains. They are, in truth, a sort of legalized robbers; and while they occasion much individual suffering, they have little or no influence over the result of the war. But their employment is principally objectionable from its having been found that, despite every precaution, it is not possible to hinder them from committing the greatest excesses. The desire to amass plunder is the ruling passion by which they are actuated; and being so, it would be childish to suppose that they should be scrupulous in their proceedings, or that they should endeavour to keep within the pale of the law when they think that their objects will be likely to be promoted by overstepping its limits. And hence their injurious treatment of the ships of neutral and friendly powers. A system of this sort may perhaps be useful to a nation which has little trade, and may hope to acquire riches by fitting out privateers, without being exposed to the risk of retaliation. But except under very peculiar circumstances, it is difficult to suppose that it should

be advantageous to a nation with an extensive over-sea trade. A notion has, indeed, been long entertained, that while the interests of humanity would be promoted, the rights of belligerents would not be injuriously affected by the abolition of privateering. It was stipulated, for instance, in the treaty between Sweden and the United Provinces in 1675, that neither party should in any future war grant letters of marque against the other; and stipulations to the like effect have since been embodied in various treaties. These, however, being only isolated efforts, were insufficient materially to abate the nuisance, which could not be put down without an agreement to that effect by the great powers, such as has been announced in the Declaration of 1856.

The United States, however, though possessed of a most extensive mercantile marine, have refused to consent to the abolition of privateering. But they have not done this capriciously; nor is it to be denied that there is a great deal of weight in the reasons given by the American government for their refusal.² They grow out of circumstances peculiar to the United States,—that is, of their warlike navy bearing but a very small proportion to their mercantile navy, which is the largest in the world. And they contend, that were they to abolish privateering, their merchant ships would be captured in vast numbers by the numerous cruisers of their enemies; while the merchant ships of the latter, owing to the fewness of their own ships of war, would be comparatively little affected; and that to restore the balance, to place themselves on a level with their opponents, they have no resource but to appeal to the patriotism (selfishness) of their citizens by licensing privateers.

The Americans have, however, intimated their willingness to assent to the abolition of privateering, provided the other powers agree not to attack or molest private ships at sea during war. Such an agreement would no doubt be very much for their advantage; but we have already seen that it is not one to which we can consent without at the same time, and by the same act, consenting to forego the use of some of the most powerful of our means of defence and attack. This, however, is about the very last thing that we either should or will do. No British statesman will ever agree to an arrangement that would diminish our powers and paralyze our energies at the very moment when, perhaps, our independence and security may depend on these being exerted to the utmost.

VI. Nothing is said in the Declaration of 1856 in regard to the right of visitation and search, probably because it is obviously inherent in belligerents; for it would be absurd to allow that they had a right to prevent the conveyance of contraband goods to an enemy, and to deny them the use of the only means by which such right can be made available. The object of the search is twofold: *first*, to ascertain whether the ship is neutral or an enemy, for everybody knows that the circumstance of its hoisting a neutral flag affords no security that it is really such; and, *secondly*, to ascertain whether it has contraband articles or enemies' property on board. All neutral ships that would navigate securely during war must consequently heave-to when summoned by the cruisers of either belligerent, and be provided with passports from their government, and with all the papers or documents necessary to prove the property of the ship and cargo; and they must carefully avoid taking any contraband articles, and perhaps also belligerent property, on board. And hence it has been generally admitted that a merchant ship which seeks to avoid a search by crowding sail or by open force, may be justly captured and confiscated.

Right of
search.

¹ L'armateur indifférent au sort de la guerre et souvent de sa patrie, n'a d'autre amour que l'avidité du gain, d'autre récompense que ses prises et les prix attachés par l'état à ses pirateries privilégiées. (Martens, *Essai sur les Armateurs*, cap. i., § 8.) This essay, which was translated into English, and published in 1801, contains the fullest details in regard to privateering. Vallin, who defends and even eulogizes privateering, admits that it is very apt *dégénérer en abus et en brigandage*. (*Traité des Prises*, i., cap. i., § 7.)

² See Letters of Mr Marcy to the Count de Sartiges, 28th July 1856.

Neuwied.

One of the most difficult questions in regard to the right of search has reference to merchantmen sailing under convoy. Is the allegation of the officer commanding the vessel of war conveying the merchantmen, that the latter have no contraband articles or belligerent property on board, to be held to be sufficient to nullify the right of search? or may the exercise of that right be notwithstanding insisted upon?

A case of this sort occurred in the early part of 1798, when a fleet of merchantmen belonging to Sweden, a neutral power, and sailing under convoy of a frigate, were detained by a British squadron. The Swedish captain, on the question being put to him, answered that the ships were destined for different ports of the Mediterranean, and that they were laden with hemp, iron, pitch, and tar. These articles were the produce of Sweden;¹ but as they have most commonly been reckoned contraband of war, and as France and her allies had many ports on the Mediterranean, there can be little or no doubt that we were warranted, despite the threatened but unattempted opposition of the Swedish captain, in detaining the ships. But besides being detained, they were condemned with their cargo as lawful prize; a proceeding which gave rise to a great deal of discussion at the time, and which it is not easy to justify.²

In the event of the captain of a vessel conveying neutral merchantmen distinctly declaring that they have no contraband articles or enemy's property on board, their detention or search would be a very strong measure. It would, in truth, be an insult to the flag and honour of the neutral power. And unless the presumptions that the captain had emitted a false declaration were exceedingly strong, to question his veracity would be an act contrary to the comity of nations, and one that a high-spirited people would be sure to resent. But except in the case of a limited number of vessels sailing to specified ports under convoy, and when there is a clear and explicit declaration by the officer in command that they have neither contraband articles nor belligerent property on board, the right of search, supposing it to be exercised without any unnecessary violence, is one that is essential to belligerents, and cannot be justly objected to. (J. R. M.)

NEUWIED, a town of Prussia, government of Coblenz, on the right bank of the Rhine, here crossed by a suspension-bridge, 7 miles N.N.W. of Coblenz. It is regularly built, in the form of a square; and the streets, which are broad and straight, intersect one another at right angles. At the west end, near the Rhine, stands the palace of the Prince of Wied, a fine building surrounded by gardens, and containing an extensive library and collections of Roman antiquities and of natural history; the latter of which was made by Prince Maximilian of Wied in North America and Brazil. Neuwied has one Roman Catholic and three Protestant churches, a synagogue, several schools, infirmaries, &c. The manufactures of the place are considerable, and consist of silk, cotton, wool, leather, hats, carpets, tobacco, chicory, hardware, beer, brandy, vinegar, &c. A large trade is carried on in manufactured articles, and also in pipe-clay, timber, iron, lead, corn, wine, and other products of the neighbouring country. The town was founded in the first half of the eighteenth century, upon the principle of affording complete toleration to every religious sect; and it rapidly rose to a flourishing condition, being peopled by Protestants, Roman Catholics, Jews, Moravians, &c. The principality

of Wied was for a long time independent, but was annexed to Prussia in 1814. Pop. 6659.

NEVA, a river of Russia, flows from Lake Ladoga to the Baltic, into which it discharges itself by several mouths at St Petersburg, after a course of about 40 miles. It forms the only outlet of the four lakes of Onega, Ilmen, Saima, and Ladoga; and owing to the vast extent of these sheets of water, that of Ladoga being the largest in Europe, it conveys an immense quantity of water to the sea. Its average breadth is 1500 feet, its depth about 50 feet; and, flowing with a velocity of 37 inches per second, it has been calculated to carry to the Gulf of Finland 116,000 cubic feet of water in a second. Such a body of water, moving at such a rate, would be exempt from the influences of frost, were it not for the long continuance of the winter, and the quantities of ice which are drifted down from the lakes by the violent storms to which they are subject. Owing to the combination of these circumstances, the river is generally frozen for four or five months in the year. The following are the dates of the opening and closing of the river by ice for each year from 1851 to 1856:—

Year.	Opening.	Closing.	Duration of Freezing.
1851.....	April 18th	December 4th	158 days.
1852.....	May 10th	October 29th	
1853.....	April 28th	November 30th	181 "
1854.....	April 26th	November 21st	147 "
1855.....	April 19th	November 23d	149 "
1856.....	April 30th	November 10th	159 "

NEVADA SIERRA. See SPAIN.

NEVERS, a town of France, capital of the department of Nièvre, stands on the right bank of the Loire, at its confluence with the Nièvre, 153 miles S.S.E. of Paris. It is built on the slope of a hill, and has a fine appearance when seen from the opposite side of the river; but the streets are narrow, steep, irregular, and dirty. Of the walls and towers that formerly defended the town some remains are still to be seen, and one of the old gates, called the Porte du Croux, still remains. The cathedral, a building of the thirteenth, fourteenth, and fifteenth centuries, stands at the top of the hill. It has a heavy appearance outside, but the interior is richly carved; and the choir contains some fine painted glass and old tapestry. The Romanesque church of St Stephen, built in 1063, is the oldest in Nevers. There are two other old churches, one of which is now used as a warehouse, and the other as a brewery. The former palace of the dukes of Nevers is now the town-hall, and the park behind it has been converted into a public garden. The town is entered from Paris by a triumphal arch, erected to commemorate the victory of the French at Fontenoy in 1745. Nevers also contains an arsenal, barracks, a college, several schools, a public library, and a society of agriculture, science, and art. It is the seat of a prefecture, of a bishopric, of a court of first resort, and of a court of commerce. The manufactures of Nevers are very considerable; that of pottery has been carried on here for eight centuries, and employs about 700 hands. Cannon and shot, chain-cables, anchors, massive machinery, implements of husbandry, violin-strings, glue, candles, beer, vinegar, ropes, and other articles are also made here. The trade of the place is also considerable; and there is a good harbour here on the river.

¹ Articles which form a considerable part of the produce of a country, though contraband of war, have sometimes been allowed to be conveyed in neutral ships. But even in that case belligerents have been accustomed to detain them, not for confiscation, but for pre-emption. (Robinson's *Admiralty Reports*, i. 244.)

² For an account of this famous case, see Robinson's *Admiralty Reports*, i., pp. 340-379. In an elaborate argument, Sir William Scott (afterwards Lord Stowell) states, with his usual ability, but with too sensible a bias, the reasons for his judgment. Its legality was questioned in a tract by Mr J. F. W. Schlegel, professor at Copenhagen, translated into English, and published in London in 1801. Schlegel was answered by Dr Croke in a tract entitled *Remarks on Mr Schlegel's Work on the Visitation of Neutral Vessels under Convoy*.

Neva
||
Nevers.

Nevin
||
Nevis.

Timber, iron, steel, coal, wool, leather, wine, cattle, and manufactured goods form the chief articles of commerce. The town is ancient, and is mentioned by Cæsar, under the name of *Noviodunum*. Here that general, in 52 B.C., fixed his head-quarters, and here he left his hostages, supplies, baggage, and military chest. After his defeat at Gergovia, the people of Noviodunum rose against the Romans, massacred all of them who were in the town, and plundered the stores. The place was afterwards called *Nevirnum*, whence the modern name is derived. It was formerly the capital of a county, which was raised by Francis I. to the rank of a duchy. It was united to the crown of France by Charles III. of Gonzaga, the last duke, who sold the duchy in 1665 to Cardinal Mazarin. It then formed the province of Nivernais. Pop. (1856) 16,082.

NEVIN, or NEFN, a town of Wales, Carnarvonshire, on the shore of Carnarvon Bay, 20 miles S.S.W. of the town of Carnarvon. The town is ill built. It has a parish church, several chapels, and a number of schools. Some trade is carried on by steam navigation with Liverpool in agricultural produce. Edward I. held a festival and tournament here, soon after his conquest of Wales; and the position of the lists can still be traced. Pop. (1851) 1854.

NEVIS, one of the Leeward Islands, in the West Indies, is situated in N. Lat. 17. 10., W. Long. 62. 42. It has an area of about 20 square miles; and consists of a single conical mountain, rising to the height of 2500 feet above the sea, and surrounded by a tract of flat, fertile, and well-cultivated land. Nevis is well watered by streams and rivulets. It was formerly thickly wooded, and even now timber is plentiful on the island, especially on the higher parts of the mountain. The surface, from the shore to a considerable height, is occupied by sugar plantations; and though the soil of the higher districts is less fertile, the climate is not so warm, and many European vegetables are successfully cultivated. The island has no harbours, but there are three roadsteads, the best of which is that of Charlestown, the capital, which stands on the shore of a large bay. Nevis contained in 1850, 380 horses, 2110 horned cattle, 1605 sheep, and 351 mules. Sugar, molasses, and rum are the chief articles of produce; and these, along with live stock, furnish the principal exports of the island. The value of the exports in 1854 was L.32,794, and of imports in the same year L.20,933. Beef, pork, meal, flour, and cotton and linen stuffs are the principal articles imported. The number of vessels that entered in 1854 was 86, and their tonnage 4921; of those that cleared 85, and their tonnage 4518. The government is in the hands of a president, who is subject to the governor-in-chief of Antigua; and there is a council of seven, and a representative assembly of nine members. For ecclesiastical purposes, the island is divided into five parishes; and there is a Wesleyan mission, which has been in operation here since 1789. There were in 1854 fourteen schools, attended by 1707 scholars; but though the state of education is thus far satisfactory, the instruction is of a somewhat superficial and unpractical character. No government aid is given to the schools. There is an hospital on the island for the poor and infirm, which receives an annual grant of L.150. The revenue in 1854 amounted to L.3875, and the expenditure to L.4123.

This island was discovered by Columbus, and named by him after the mountain Nieves in Spain, to which it bore some resemblance. It was first settled by the British in 1628 from the neighbouring island of St Kitt's, and soon rose to a high pitch of prosperity and importance; but in the end of the seventeenth and beginning of the eighteenth century it suffered severely from the ravages of an epidemic, the hostilities of the French, and the devastation of a hurricane. Nevis afterwards gradually regained its prosperity; but since the emancipation of the slaves it has been gradually declining; the proprietors, from their aversion to

that measure, having endeavoured to preserve as much as possible of the old system, which had ceased to be applicable or beneficial in the present state of society, instead of adopting a system suitable to the changed state of affairs. The absence of any law respecting the relations of master and servant produces mutual distrust; and the acquisition of wealth by the Negroes is still discouraged by their employers. The white population does not exceed 60 adult males; while the whole population is estimated at more than 10,000.

NEVYLE, or NEVILLE, ALEXANDER, an old English author, was born in Kent in 1544. He is best known by an elegant and spirited metrical version, or rather paraphrase, of Seneca's *Ædipus*. It was written as early as his sixteenth year; and was printed in 1581 in a collection entitled *Seneca his Tenne Tragedies translated into English*. Nevyle is also known as the secretary to the famous Parker, Archbishop of Canterbury, and as the author of a Latin narrative of Kett's Norfolk insurrection, printed in 1575; and the Cambridge verses on the death of Sir Philip Sidney printed in 1587. His death took place in 1614.

NEW ALBANY, a town of the United States, North America, Indiana, is situated on the right bank of the Ohio, 3 miles below Louisville, and about 100 S. by E. of Indianapolis. It is one of the largest and most commercial places in the state; and has broad and handsome streets regularly laid out. There are about twelve churches, several schools, a theological seminary, a court-house, and a jail. Two newspapers are published here. Ship-building, especially that of steamers, is carried on here; and there are also machine-works, flour-mills, saw-mills, &c. It forms the southern terminus of the New Albany and Salem Railway, which extends as far N. as Michigan city. Pop. (1850) 8181; (1853) about 12,000.

NEWARK, a town of the United States of North America, state of New Jersey, is situated on the Passaic, 4 miles from its mouth, and 9 miles W. of New York. It is regularly laid out, with broad and straight streets intersecting each other at right angles; and has two spacious public squares, which are planted with fine elm trees. The court-house is a large structure of brown stone in the Egyptian style. The library building is also very handsome, and contains a public hall and a gallery of paintings. There are many fine churches in the town, three of which have elegant and lofty spires. They belong to Roman Catholics, Methodists, and Presbyterians. There are in all about forty churches of various sects in Newark. Among the literary and educational institutions are,—a historical society, a literary association, a Wesleyan institute, and seven schools, attended by about 2500 scholars. The chief importance of the town is derived from its extensive manufactures, of which the establishments for the production of India-rubber goods, of carriages, and of machinery are the largest and most important. Leather goods and articles of clothing are also manufactured. The trade of the city is principally coasting. The registered and enrolled shipping in 1852 had a tonnage of 5107, of which 1189 were propelled by steam. In the same year the number of ships that entered was 21, and their tonnage 2304; of those that cleared 13, tonnage 1393. Pop. (1850) 38,893; (1853) about 45,500.

NEWARK-UPON-TRENT, a market-town, and municipal and parliamentary borough of England, county of Nottingham, on an affluent of the Trent, 20 miles N.E. of Nottingham, and 124 N.N.W. of London. It is well though irregularly built, and has a large market-place in the centre. The parish church is one of the largest and finest in England; and though originally a Norman building, it underwent great changes in the time of Henry VI. It is in the form of a cross, has a lofty spire, and contains some fine painted glass, carved wood-work, and ancient monuments. To the N.W. of the town are the remains of an ancient castle, which was either built or repaired by Bishop Alex-

New
Brunswick

ander in 1125. King John died here in 1216; Wolsey lodged here after his fall in 1530; and in the neighbourhood Charles I. surrendered himself to the Scotch commissioners in 1646. Newark has Wesleyan Methodist, Baptist, Independent, and other chapels; a town-hall, court-house, several schools, and almshouses. A considerable trade is carried on in malt, flour, corn, wool, cattle, and coal; and the commerce of the river is facilitated by the wharves and warehouses which have been constructed here. A county court is held at Newark; and there are six annual cattle fairs. The borough returns two members to the House of Commons. Pop. (1851) 11,330.

NEW BEDFORD, a town of the United States of North America, in the state of Massachusetts, is situated on the estuary of the Acushnet, an arm of Buzzard's Bay, 55 miles S. of Boston. It stands on the slope of a hill, and is for the most part built of wood. The streets, which are straight and regular, are generally lined with trees, and many of the houses are surrounded by gardens. The town-hall is a very handsome building of granite, 100 feet long, 60 wide, and three storeys high. There is also a fine granite custom-house. New Bedford contains about 20 places of worship belonging to various denominations, and numerous public schools. The manufactures are considerable, but principally in connection with the whaling trade, in which the town is extensively engaged. Ship-building and coopering are largely carried on. In the year ending June 30, 1852, 18 vessels were admeasured, having a tonnage of 5626. There are more than twenty manufactories of oil of various kinds, and several planing-mills, rope-works, iron-works, &c. The shipping of New Bedford is chiefly employed in whaling; and the total amount registered and enrolled had in 1852 a tonnage of 149,208, of which 125,530 tons were employed in the whale fishery. The number of ships that entered in that year was 113, with a tonnage of 27,940; those that cleared 174, with a tonnage of 55,347. Pop. (1850) 16,443; (1853) about 17,500.

NEWBERN, a town of the United States of North America, in North Carolina, stands at the confluence of the rivers Neuse and Trent, 120 miles S.E. of Raleigh. It was formerly for some time the capital of the state. It has a court-house, jail, theatre, public hall, and several churches and schools. The trade of the place is considerable, and the river is navigable for steamers for eight months in the year. Grain, timber, turpentine, tar, and naval stores are exported. The registered and enrolled tonnage of the port in 1852 was 5235. The vessels that arrived in the same year were 22, tonnage 2822; those that cleared 24, tonnage 3151. Pop. (1850) 4722.

NEW BRITAIN, an island in the Pacific Ocean, N.E. of New Guinea, between S. Lat. 5. and 7. 30., and E. Long. 148. and 153. It is separated from New Guinea by Dampier's Strait, which is about 40 miles broad, and from New Ireland by St George's Channel. The outline is irregular, and the area is 24,000 square miles. The surface is mountainous, rising to a considerable height, and well wooded on the sloping sides. In some places the mountains extend quite to the coast; but in others there are extensive plains stretching along the shore. The highest summit in the island has been observed to emit smoke. The soil is fertile, and produces bananas, bread-fruit trees, sago palms, coconut palms, and other trees; besides sugar-canes, bamboos, yams, ginger, &c. The animal kingdom is represented by dogs, pigs, turtle, and fish in large numbers. The New Britons resemble the Papuans in their stout, well-proportioned figures and dark complexions. They are numerous and entirely uncivilized, without any articles of clothing.

NEW BRUNSWICK, a colony of Great Britain in North America, lying between N. Lat. 45. and 48. 5., W. Long. 63. 50. and 67. 53.; and bounded on the N. by the

it from Lower Canada; E. by the Gulf of St Lawrence; S. by Nova Scotia and the Bay of Fundy; and W. by the state of Maine. Its length from N. to S. is 180 miles; breadth, 150; area, 27,704 square miles. Its form is that of an irregular quadrangle, and the length of its coast-line is about 500 miles.

The surface of New Brunswick, though not presenting very striking varieties in the character of the different parts, may be divided into three regions, differing to some extent from each other in nature and aspect. The southern region comprises the tract of land which stretches along the Bay of Fundy, and is divided into two unequal parts by the River St John. The whole coast of this region is bold and rocky, and the surface is much broken and diversified with rocks and ravines. To the W. of the St John the soil is deep and fertile, and covered with tall and dense forests. To the E. of that river the soil is not so fertile, but there are many beautiful valleys covered with forests mixed with corn-fields, and traversed by streams flowing into lakes at the bottom of the valleys, and ultimately joining the St John. The coast of the central region, along the Gulf of St Lawrence, is low and sandy, covered with trees of a small size. For nearly 20 miles inland the country is flat, and consists of marshes and mosses; but in the interior it rises into gently-sloping hills and undulations, which extend westward as far as the St John. The northern and north-western parts of New Brunswick are more mountainous than any of the other regions. A branch of the Alleghany Mountains traverses the N.W. corner of the province, from the borders of Maine to the Bay of Chaleurs. The mountains are not of any great height; and while some are bold and precipitous towards the top, others are of a more rounded form, and many of the hills are clothed with wood to their summits. The scenery of this district is exceedingly varied and beautiful; the mountains and glens contrast finely with the rich valleys, the rivers, cataracts, and lakes, that are everywhere seen; and the immense forests add to the beauty and luxuriance of the view. It is these forests that form the most striking feature of New Brunswick, and constitute not the least part of its value to the colonist. The principal trees are those belonging to the order of pines, which occupy most of the low-lying land in the province. Pines, larches, and spruces occur in great abundance; and the rocky shores of the Bay of Fundy are rendered extremely picturesque, especially in winter, by the dark-green clumps of spruces contrasting finely with the snow which lies around, and standing firm against the winds and storms which agitate the waves beneath. The oak, ash, maple, birch, poplar, and many other trees, are also found in New Brunswick, affording inexhaustible supplies of timber, and giving the forests in autumn a most gorgeous and rich appearance from the varied tints of their foliage and flowers.

A circumstance that adds greatly to the resources of the country and the beauty of the scenery, is the number of lakes, rivers, streams, and lakes with which it is watered. Hardly any part of the country is destitute of some stream, of greater or less size; and in some parts of the interior a canoe can be conveyed with equal ease to the Bay of Chaleurs, the Gulf of St Lawrence, or the Bay of Fundy. The largest river is the Looshtook or St John, which rises in a lake of the same name in the state of Maine, flows first N.E. and afterwards E., forming part of the boundary between Maine and Canada. It then enters New Brunswick, and flows S. and S.E., till it falls into the Bay of Fundy at St John's, after a course of 450 miles. About 225 miles above its mouth, where the river enters New Brunswick, occur the Grand Falls, a cataract 58 feet in height, over which the rocks rise steeply to the height of 100 or 150 feet. The St John is navigable for large

New
Brunswick

Surface.

Rivers and
lakes.

New Brunswick. smaller vessels can ascend to the falls. Above them it is navigated by steamers for 40 miles, to the mouth of the Madawaska; and small boats and canoes may proceed as far as the source. The St John receives many tributaries, among which the most important is the Tobique, which joins it on the left from the mountainous region of New Brunswick; and in the lower part of its course there are several lakes communicating with the river, the largest of which, Grand Lake, about 50 miles from the sea, is 30 miles in length, and varies from 3 to 9 in breadth. The river and bay of Miramichi are noticed in a separate article. The Ristigouche, which marks the boundary between New Brunswick and Canada, is formed by five main branches; and from this circumstance it derives its name, which signifies in the Indian language, "the river that divides like the hand." It has a length of 100 miles, and falls into the Bay of Chaleurs, having at its mouth a breadth of 3 miles and a depth of 9 fathoms. The Nipisigit waters the north-eastern part of New Brunswick, and falls into the Bay of Chaleurs after a course of 100 miles. Next to these the most important river in the province is the Peticodiac, which falls into the north-eastern extremity of the Bay of Fundy. It is navigable for large vessels to the distance of 25 miles from its mouth.

Geology
and mine-
rals.

The geological structure of New Brunswick resembles in its general arrangement that of most other parts of North America. The different formations extend either parallel to the branch of the Alleghanies, which crosses the country from S.W. to N.E., or parallel to the shores of the Atlantic. These mountains consist of granite, syenite, trap, porphyry, and other rocks; and in other parts of the province the Silurian, the Carboniferous, and the Old Red Sandstone strata occur. The geology of the interior of New Brunswick is not minutely known, owing to the country being so little cleared. Several excellent salt springs are found, especially in Sussex Vale, to the N.E. of St John's. Many of the strata of New Brunswick are very rich in fossil remains, which are remarkable in many cases for the distinctness and perfection with which they have been preserved. Of the mineral riches of the province, the most important item is coal, of which there is an immense quantity to be found. A vast coal-field occupies the central counties, covering an area of between 7500 and 10,000 square miles, or about one-third of the whole extent. Iron has been found in great abundance, and of excellent quality for steel, at Woodstock on the St John; and copper on the banks of the Nipisigit.

Climate
and agri-
culture.

The climate of New Brunswick, like most of the adjacent parts of North America, is more subject to extremes than places of the same latitude in the Eastern Continent. At Fredericton the temperature ranges from 35° below zero to 95° above, and the mean temperature is about 42°. The severest part of the winter is from the middle of December to the middle of March; but the deepest snows do not fall till the end of February or beginning of March, when the winds blow from the E. with great fury, piling up the snow in drifts and banks. About the middle of March the south winds begin to blow with considerable strength, and soon afterwards the ice disappears from the rivers and lakes, and the country becomes fit for the plough. The spring is short, and generally cold and rainy; but during the summer very little rain falls, except in thunder-storms, which are frequent. The finest part of the year in New Brunswick is the autumn, and especially what is called the Indian summer, which occurs in the month of November. At this period the varied hues of the forest, the dryness and clearness of the atmosphere, and the brilliancy of the northern lights, all combine to increase the beauty of the scenery. The climate of the coast is somewhat more moist than that of the interior. The clearing of the country, which is rapidly going on, seems to be producing a gradual increase in the mildness of the inland regions; for while the

winter formerly lasted for six months, it now rarely exceeds three or four. The climate is extremely healthy: epidemics are rare; rheumatism, low-typhus, and consumption are the only prevalent diseases; and there have been many remarkable instances of longevity in the province. The soil of New Brunswick is very good; and though the severity of the winters is unfavourable to the growth of some kinds of crops, potatoes, turnips, pulse, wheat, oats, rye, and barley thrive extremely well here. The largest crop raised, however, is that of hay, which is not only sufficient to supply the cattle with fodder, but is also exported in considerable quantities to the United States. The forests of New Brunswick, having been as yet but partially cleared, and as the occupation of cutting and sawing wood is more profitable than that of farming, agriculture has made but little progress, and the produce of the country is not sufficient to supply the wants of the inhabitants. The cultivation of the land, however, is rapidly extending; and improvements are being gradually introduced, which will render the produce of the soil more commensurate with its natural fertility. The amount of land under cultivation in the province in 1851 was 643,954 acres; and the crops raised in 1855 were,—of wheat, 206,635 bushels; of barley, 74,300; of oats, 1,411,164; of buck-wheat, 689,004; of Indian corn, 62,228; of pulse, 42,663; of turnips, 539,803; of potatoes, 2,792,394; of other roots, 47,880; and of hay, 225,093 tons. The number of horses in the same year was 22,044; of horned cattle, 106,263; of sheep, 168,039; and of swine, 47,932.

New
Brunswick.

Besides farming, the people of New Brunswick are employed for the most part in the fisheries; in the lumbering and commerce. business, as it is called,—that is to say, in cutting down timber from the woods, and preparing it for exportation; and in ship-building. The nature of the coasts of the province affords great facilities for fisheries; and the great abundance of fish which is to be got here would render fishing a profitable pursuit. It is not, however, carried on to a very great extent; for though many of the inhabitants of the coast pursue this occupation, along with those of farming and lumbering, yet the demand for timber and the scantiness of the population give greater encouragement to other occupations; while the idleness of the people and the encroachments of American fishermen prevent this employment from being prosecuted with as much activity as it might be. In consequence of the recent reciprocity treaty with the United States, admitting the produce of the colonial fisheries free of duty into that country, it is believed that the fisheries of New Brunswick will be more actively carried on and more highly valued than hitherto. The principal seats of the fisheries are in the harbour of St John's, and on the islands at the mouth of the Bay of Fundy. Cod, haddock, herring, and mackerel, are the principal fish got here; and the total value of the fisheries in the Bay of Fundy was, in 1850, L.52,700. The occupation of lumbering, in which a great part of the inhabitants are employed, though it is not favourable for the agricultural progress of the country, serves to clear out and open up the forests; and produces an active, hardy, and industrious set of men. The timber is floated down the rivers to the saw-mills, of which there are in the province a large number. The exports of New Brunswick consist principally of timber and fish. The total value of the wood exported in 1854 was L.740,157; and that of the fish, L.55,359. The total value of the exports in 1855 was L.826,381, and of the imports, L.1,431,330. The number of ships built in the province in 1854 was 135, and their tonnage 99,426; in 1855 the number of ships was 95, and their tonnage 54,561. The number belonging to the province on the 31st December 1854 was 878, tonnage 141,454; at the same date in 1855 the number of ships was 866; and the tonnage 138,292. The number of vessels that

New Brunswick. entered the various ports in 1855 was 3442, tonnage 590,767; those that cleared in the same year 3381, tonnage 663,981. The number of saw and grist mills in the province in 1851 was 845, employing 4668 hands. There were also in the same year 125 tanneries, employing 255 hands; 11 foundries, employing 242; 52 weaving and carding establishments, producing 622,237 yards of cloth, and employing 96 hands; 8 breweries, producing 100,975 gallons of malt liquors; and 94 other factories, employing 953 hands.

Divisions and government.

The province is at present divided into fourteen counties, some of which, however, are but thinly peopled; and portions of land have been reserved for the aboriginal Indians, of whom there were in 1851, 1116 still remaining. The extent of land set apart for them is 61,273 acres. The government is in the hands of a lieutenant-governor, with an annual salary of L.3000, who is aided by an executive council of eight, a legislative council, and a representative house of assembly. The public revenue in 1855 amounted to L.93,916; and the expenditure in the same year was L.138,353. The judicial establishments of New Brunswick consist of a supreme court of four judges, a court of chancery, one of marriage and divorce, and one for the trial of offences committed at sea; the three last of which are presided over by the lieutenant-governor. There is also a court of vice-admiralty, and one of probate. The number of barristers in the colony, practising also the business of attorneys, was, in 1849, 155. The military force of the colony consists of a regiment of yeomanry cavalry, 3 separate troops of cavalry, a regiment of artillery, and 18 regiments of infantry, numbering in all 27,200 rank and file.

Religion and education.

The religious sects in New Brunswick are Episcopalians, Presbyterians, Methodists, Baptists, and Roman Catholics. None of these sects are supported by the government; but the Bishop of Fredericton takes precedence next to the lieutenant-governor and the commander of the forces. The diocese of Fredericton was created in 1845, and included in 1849 a bishop, an archdeacon, 33 rectors, and 8 curates, with 61 churches, capable of containing 17,920 people. The synod of New Brunswick in connection with the Established Church of Scotland consists of 13 ministers; and the synod in connection with the Free Church of Scotland consists of 17 ministers. The Wesleyan Methodists had, in 1847, 21 ministers and 33 local preachers in the province. The Baptists, who are divided into various sects, had, in 1846, 41 ministers; and the Roman Catholics, in the same year, 1 bishop and 24 priests. The whole number of places of worship in the colony in 1851 was 423. Education is well attended to in New Brunswick. There is a university at Fredericton, founded in 1828, and constituted after the model of those of Oxford and Cambridge. It receives annually from the crown a grant of L.1000, an equal sum from the provincial legislature, and has an endowment of 6000 acres of land near Fredericton. There are also Baptist and Methodist colleges in the province. Grammar and parish schools have been established in every county; the management of the former being in the hands of a board of trustees appointed by the lieutenant-governor and council, who themselves form a board of education for the superintendence of the parish schools. The parish schoolmasters receive government allowances, varying from L.18 to L.30 per annum. The whole number of schoolhouses in 1851 was 798. The public charitable institutions consist of a marine hospital, a lazaretto, and a provincial lunatic asylum. The amount of money expended in 1854 for educational and charitable purposes was L.17,269.

History and population.

The early history of New Brunswick is closely connected with that of Nova Scotia, of which it originally formed a part, when that province, then called Acadia or New France, was under the French dominion. The earliest

attempt at colonization here was made in 1639; and in 1672 a number of French emigrants settled on the Miramichi and in other parts of the country. In 1713 New Brunswick was ceded to Great Britain, in terms of the treaty of Utrecht. The country was first settled by British colonists in 1764; and in 1784 New Brunswick was separated from Nova Scotia, and made a distinct province. It was originally peopled by several different Indian tribes; but these have all now disappeared except two,—the Micmacs and the Melicetes,—who, though resembling each other in physical appearance, differ considerably in their origin and language. They wander in families about the country; but an annual council is held, at which arrangements respecting their hunting, fishing, and other affairs, are made. The European inhabitants of the province consist to a large extent of descendants of royalists from the United States, who left their country at the American revolution, that they might remain under the British sway.

The capital of New Brunswick is Fredericton, in the county of York, on the St John, 88 miles from its mouth. **Principal towns.**

It stands on a plain bounded on one side by the river, which is here three-fourths of a mile broad, and on the other by a range of hills, 2 miles long and half a mile wide; and it is regularly built with long and straight streets. The most of the houses are of wood, but the public edifices are of stone, and some of them are very handsome. This town has a cathedral, five or six churches, a province-hall for the accommodation of the courts of law and legislature, a government-house, library, barracks, and other buildings. Pop. about 6000.

St John's, the principal commercial town in the province, is situated on a rocky promontory at the mouth of the St John River, in N. Lat. 45. 20., W. Long. 66. 3. It is regularly and well built; but the streets are in some places very steep, although much labour has been expended in reducing them to a level. There are many handsome public buildings of stone, brick, and wood, among which are a court-house, church, and bank. The extreme point of the promontory is defended by two batteries; and here are also barracks and military stores. The number of new vessels registered at St John's in 1854 was 97 (besides which 11 vessels were built for owners in the United Kingdom), aggregate tonnage 81,379; in 1855 the number was 76, and the tonnage 40,986. At 31st December 1855, 566 vessels, of 110,451 tons burden, belonged to the port. The number of vessels that arrived in 1851 was 1527, tonnage 282,450; those that cleared 1545, tonnage 324,821. The total value of the imports in the same year was L.826,398, and that of the exports L.535,441. Pop. about 12,000. The population of the various counties of New Brunswick in 1851 was as follows:—

Albert	6,313	Queen's	10,634
Carleton	11,108	Restigouche	4,161
Charlotte	19,938	St John's	38,475
Gloucester	11,704	Sunbury	5,301
Kent	11,410	Victoria	5,408
King's	18,842	Westmoreland	17,814
Northumberland	15,064	York	17,628
Total		193,800	

NEW BRUNSWICK, a town of the United States of North America, capital of Middlesex county, in the state of New Jersey, stands on the right bank of the River Raritan, 26 miles N.N.E. of Trenton, and 30 S.W. of New York. The older part of the town, which is built on the low ground close to the river, has narrow and irregular streets; but on the hill which rises behind there is a more recent portion, with broad streets and many handsome edifices. Rutgers' College, a building of dark red freestone, situated on a hill, has 7 professors, 66 students, and a library of 10,000 volumes. There is also here a theological seminary of the Dutch Reformed Church, with 3 professors, 34 students, and a library of 7000 volumes. New Brunswick has

New Brunswick.

Newburg
||
Newbury-
Port.

about ten churches, several schools, two banks, a court-house, and a jail. The Raritan is navigable as far as this place, and the town is connected with Bordentown, 42 miles distant, by the Delaware and Raritan Canal. It is also a station on the New Jersey Railway, and has a considerable trade. Pop. (1850) 13,070.

NEWBURG, a town of the United States, North America, state of New York, on the right bank of the Hudson River, 84 miles S. of Albany, and 61 N. of New York. The ground on which it is built gradually rises from the water's edge to the height of 300 feet. It is well built; and contains ten churches; a court-house; jail; theological seminary of the Associate Reformed Church, with about 11 students, and a library of 3200 volumes; several schools; and five banks. Newburg has large manufactories of cotton, wool, machinery, flour, plaster, leather, &c., and an active trade is carried on in grain, flour, and dairy produce, for which the surrounding country is famous. Pop. 11,415.

NEWBURGH, a royal burgh and market-town of Scotland, county of Fife, is situated on the right bank of the Firth of Tay, 9 miles E.S.E. of Perth. It is well built, and has one principal street running along the shore, and crossed at right angles by another leading to the harbour, which is formed by several piers extending into the river. The town has a town-hall with a spire, a large parish church, two United Presbyterian churches, Baptist and Independent churches, and several schools. The harbour is pretty good, admitting vessels of 500 tons burden; and some trade is carried on in corn, timber, linen, and coal. The inhabitants are principally employed in the weaving of coarse linens. In the neighbourhood of Newburgh are the ruins of the abbey of Lindores, and two curious antique crosses. The town is ancient, and was made a burgh in 1457. Pop. of the burgh (1851) 2638.

NEWBURY, a municipal borough and market-town of England, county of Berks, on the right bank of the Kennet, 16 miles W. by S. of Reading, and 56 W. by S. of London. The river is here crossed by a stone bridge of three arches; and the town, which is well built, has two principal streets, which are broad, and arranged in the form of the letter 'T'. There is a large market-place in front of the parish church, which is a large but plain stone building of the age of Henry VII. The town contains also places of worship for Wesleyan Methodists, Independents, Baptists, Quakers, and Unitarians, and a new Episcopal church has recently been erected in the Gothic style. There is also in Newbury a substantial town-hall, jail, alms-houses, large workhouse, dispensary, literary institution with library, and several schools. The Kennet supplies water-power for several large corn-mills in the town and neighbourhood; and there are also silk and paper mills, malthouses, and breweries, in and about Newbury. The manufacture of woollen cloth was formerly carried on to a much more considerable extent than at present; and the place was of much importance in the days of posting, from its position on the road to Bath. It is now connected with the metropolis by a branch of the Great Western Railway. Some trade is carried on in malt and flour; and horse and cattle fairs are held thrice a year. Two engagements were fought here during the civil war in 1643 and 1644, in both cases with doubtful issue. Donnington Castle, not far from Newbury, to the N.W., was the property of Chaucer the poet, who is believed to have spent there the last years of his life. Pop. (1851) 6574.

NEWBURY-PORT, a seaport of the United States of North America, Massachusetts, situated on a gentle slope on the right bank of the Merrimack, 34 miles N. by E. of Boston. It is regularly built, with wide streets, some of which rise in terraces parallel to the river, and in its centre is a pond about six acres in extent, which is surrounded by fine pleasure-grounds. The custom-house is a large granite building, with a fine colonnade in the Grecian style; the

city hall, a handsome building, has recently been erected at the cost of about L.7000; and there are also a court-house; 16 churches, belonging to various sects; and about 30 schools. There is a lyceum, at which lectures are delivered; and a public library has recently been established. Newbury-Port has five manufacturing companies, employing in all from 1500 to 1600 hands, and an aggregate capital of L.246,000. Cotton goods are principally produced; but iron, machinery, leather, boots, shoes, &c., are also among the manufactures. The harbour is large and safe, though there is a shifting sand-bank at its mouth. The registered and enrolled shipping of the port at June 30, 1852, had a tonnage of 29,430. The number of vessels that arrived in that year were 110, tonnage 9231; those that cleared 116, tonnage 10,140. George Whitfield died here in 1770, and his remains are buried in one of the churches of the town. Pop. (1850) 11,318; (1853) about 13,000.

NEWCASTLE, a market-town of Ireland, county of Limerick, situated on the Arra, 25 miles S.W. of Limerick, and 144 S.W. by W. of Dublin. It is a neat country town, with four principal streets and a large square. The parish church is a fine building; and the town has also a Roman Catholic church, two schools, town-hall, market-house, barracks, fever hospital, dispensary, workhouse, and the remains of an old castle that once belonged to the Templars, but is now the residence of the Earl of Devon. Coarse cloth is the principle article of manufacture here, and dyeing and bleaching are also carried on. Pop. (1851) 2513.

NEWCASTLE-EMLYN, a market-town of Wales, in the county of Caermarthen, is pleasantly situated on the banks of the Teifi, 16 miles N.W. by N. of Caermarthen, and 229 W. by N. of London. It was anciently called *Dinas-Emlyn*, or the "City of Emlyn;" and a castle existed here at a very early period. It was rebuilt in the time of Henry VII. by Sir Rhys-ap-Thomas, and the place then obtained the name of Newcastle. The castle was held by the royalists during the civil war, but after that period it gradually fell into decay, and only the ruins now remain. The town is well built, and contains an Episcopal, a Baptist, and other churches; a school; and a savings-bank. Some trade is carried on in cattle, for which there are eleven yearly fairs. Newcastle-Emlyn is included in the parish of Kenarth, which had in 1851 a population of 1980.

NEWCASTLE-UNDER-LYME, or *under-Lyme*, a market-town and municipal and parliamentary borough of England, in the county of Stafford, on the right bank and near the source of the Trent, 16 miles N. by W. of Stafford, and 150 N.W. of London. It is well though irregularly built, chiefly of brick, on the slope of two hills; and contains a handsome town-hall; two Established churches, one of which has an ancient square sandstone tower; besides Methodist, Independent, Baptist, and Roman Catholic churches; a literary and scientific institution, with a library; a theatre; a savings-bank; and a range of alms-houses founded by Christopher Monk, Duke of Albemarle, son of the celebrated general. The principal manufacture carried on here is that of hats, but there are also silk and paper mills, and a cotton factory; while shoes, clocks, and earthenware are also produced. In the neighbourhood there are coal-pits and iron-works. An old castle, of the time of Henry VII. formerly stood here, but no remains of it have been preserved. The borough returns two members to Parliament. Several fairs and cattle markets are held here annually. Pop. (1851) 10,569.

NEWCASTLE-UPON-TYNE is situated, as its name denotes, on the River Tyne, about 8 miles from the sea in a direct line, and exactly 10 miles by the course of the navigable channel. It is a county within itself, having its own sheriff and other officers distinct from the county of Northumberland, of which it originally formed part. The assizes for Northumberland are, however, still held in Newcastle,

Newcastle
||
Newcastle-
upon-
Tyne.

Newcastle-
upon-
Tyne.

the court-house and its precincts being exempt from the jurisdiction of the municipal authorities. The Tyne is formed by the confluence of two streams, of which the North Tyne rises near a place called Deadwater, on the confines of Liddesdale in Scotland; the South Tyne has its source near the mountain of Crossfell in Cumberland. The point of junction is near Warden, a village 2 miles W. of Hexham, from which town the united stream flows past Newcastle, and thence between the towns of North and South Shields, discharging its waters into the German Ocean at Tynemouth, the ruins of the ancient monastery at which place forms a conspicuous landmark on the north of the entrance to the port. In the night a revolving light is constantly kept burning, and exhibits a face every minute. The River Tyne commissioners are at this time (1858) erecting substantial stone piers at the entrance of the harbour, which, when completed, will add greatly to the safety of ships trading to the Tyne.

Naviga-
tion.

Within the river, near the town of North Shields, there are two lighthouses for the use of vessels passing over the bar. There are three warping buoys within the river, two on the south and one on the north side; and in addition to these there is a distinguishing buoy on the north side, where the low light is situated. The tide flows up the Tyne from Shields to a distance of 18 miles; and at Newcastle Bridge it generally runs upwards about four hours and a half, and downwards about seven hours and a half. The perpendicular rise at the bar at Tynemouth is about 18 feet, and at the bridge from 11 to 12 feet. It is high-water on the bar, at the full and change of the moon, at about three o'clock, if the weather be settled; but a strong northerly wind will sometimes make it high-water an hour sooner, and a strong southerly wind an hour later, than the regular course; and there will be at times 2 or 3 feet more water on the bar with a strong northerly wind than with a strong southerly one. The commissioners are making great exertions to improve the navigation of the river, and employ a powerful steam-engine for the purpose of dredging.

Trinity
House
bridges.

Due precautions against accidents to shipping have been rendered necessary by the vast number of vessels that pass up and down the Tyne; and an association, formed in 1825 at the Trinity House, has for its object the preservation of lives from shipwreck and the maintenance of a life-boat at South Shields. The pilots on the river, and the sea-pilots, connected with the port of Newcastle, with all its creeks and harbours, which extend from Holy Island on the north to Whitby on the south, are about 800 in number, and are under the regulation of the corporation of the Trinity House, who have a spacious hall, a chapel of very ancient workmanship, and alms-houses for poor brethren and widows, situated in Trinity Chare, near the quay. This ancient society is governed by a master (elected annually) and twelve brethren, who hold a common seal. The charter of this corporation was renewed by King Henry VIII. in 1536, and confirmed by Queen Mary in 1553, and also refounded by Queen Elizabeth in 1584. The bridge was founded in very ancient times, and consisted of wood. It was once burnt, and at subsequent periods was more than once carried away by the floods. The existing bridge was built between the years 1775 and 1799. It was only 21 feet wide, which, as the population and trade increased, was found very inconvenient; and in 1801 it was enlarged and widened, and is now 33 feet 6 inches in width. It connects the town of Newcastle with its suburb Gateshead, which is in the county of Durham. The inadequacy of this means of communication between the opposite sides of the river was long a subject of complaint, and several attempts were from time to time made to secure the erection of a second bridge on a high level, so as to avoid the dangerous declivities of both banks. All these failed in consequence of the magnitude of the capital

required, until the formation of a company to complete the eastern line of railway communication between London and Edinburgh. The promoters of this scheme, now carried into successful operation, undertook, on the solicitation of the inhabitants and others interested, to make the bridge which was necessary for the transit of the railway available also for ordinary traffic; and to their liberality and enterprise, under the scientific direction of Mr Robert Stephenson, the public are indebted for that magnificent structure, the "High-Level Bridge." The design is as remarkable for its originality as for its grandeur; the structure consisting of two distinct roadways, one above the other,—the lower appropriated to ordinary traffic, the upper to the railway,—their respective elevations above the level of the river being 90 and 118 feet. The piers of the bridge are of stone, and are six in number,—one on the margin of the river on each side, and four in the stream, the distance between each being 124 feet. The railway works within the town of Newcastle, including the High-Level Bridge and the purchase of property, entailed an expenditure on the company of upwards of half a million sterling.

Newcastle-
upon-
Tyne.

The quay lies immediately to the east of the old bridge, Quay and wall. and was considered, previous to the introduction of wet docks in our principal ports, as the finest wharf in England. Its length was nearly 550 feet, to which a further length of 1000 feet has been added by the corporation. The new portion, however, still presents an unsightly appearance, in consequence of the delay which has occurred in effecting the contemplated removal of a mass of property of the very worst description, and the erection of buildings which would have presented a handsome elevation to the river. The old quay appears even more desolate, from the disastrous effects of a tremendous explosion which occurred in the neighbouring town of Gateshead in 1854, involving an unprecedented destruction of property on both sides of the river. The town-wall formerly ran between the warehouses on the quay and the river, to the great obstruction of commerce, but was removed about the middle of the last century. Other portions of the wall have from time to time been removed without any pressing necessity, and little of it now remains. Leland, who saw it in its integrity, says,—“The strength and magnificence of the walling of this town far passeth all the walls of the cities of England, and of most towns in Europe.” Sir Ralf Sadleir gives similar testimony.

From an early period Newcastle has been chiefly indebted Coal trade. for its mercantile importance to the extensive coal-fields adjacent. The cinders of this mineral discovered amongst the ruins of several of the Roman stations in Northumberland show that its use was not unknown to the imperial legions in Britain, although the abundance of wood everywhere available for fuel necessarily confined the consumption of coal to the immediate locality in which it was produced. During the Saxon period we have no notice of coal either as an article of commerce or of domestic consumption, although it is probable that where the seams were easily accessible they were not altogether neglected. The earliest authentic records of the Newcastle coal trade, after the Conquest, is found in a charter of Henry III. to the burgesses, A.D. 1239, in which he grants them license to dig coal in the Forth and Castle field, within the liberties of the borough. From an inquisition in the reign of Edward I. it appears that, in consequence of the rapid development of this traffic, the revenues of Newcastle were then worth L.200 per annum, although they had been granted by King John at a fee-farm rent of L.100 per annum, which was more than their then estimated value. In 1306 the use of sea-borne coal must have been general in London, as in that year Parliament complained to the king of its infecting the air with noxious vapours, in consequence of which the use of coal was prohibited, and

Newcastle-upon-Tyne. strict orders given to destroy all furnaces and kilns in which it was used. Coals, however, must have again come into use in 1327, as at the coronation of Edward III. a debt appears to have been due for this mineral; and in the same reign orders were issued relating to the measuring of coals; and such as were got in the field of Gateshead were to be taken across the Tyne in boats, and, after paying the custom-duty, to be sent to any port of the kingdom, but to no port out of the kingdom except to Calais. About the year 1338 the Prior of Tynemouth granted colliery leases. In the year 1582 Queen Elizabeth obtained a lease for ninety-nine years of the manors and royalties of Gateshead and Whickham for L.90 per annum, which caused the price of coals in London to rise to 9s. the chaldron; upon which the lord mayor made applications to Lord Burleigh that the price might be reduced to 7s. In 1615 the trade appears to have employed 400 sail of ships, some of which sailed to France, and others to the Netherlands. During the civil wars the trade and the prices of coal fluctuated much, as at one time London was with the Parliament, and Newcastle with the royal party. In 1675 the shipping of Newcastle was estimated at 80,000 tons. In 1710 the annual average export for the three preceding years had amounted to 178,143 chaldrons, and in 1776 to 260,000. The following account will show the vast but gradual increase since that time:—

An Account of the Quantity of Coals shipped at Newcastle from 1794 to 1835, distinguishing those sent Coastwise and those over Sea.

Year.	Coastwise.	Over Sea.	Year.	Coastwise.	Over Sea.
	Chaldrons.	Chaldrons.		Chaldrons.	Chaldrons.
1794	388,724	39,935	1820	756,513	44,826
1800	537,793	47,487	1825	687,029	51,444
1805	552,827	49,572	1830	817,870	74,456
1810	632,299	17,258	1835	853,359	116,803
1815	650,209	42,834			

The preceding account is given in Newcastle chaldrons, which weigh 53 cwt., but the London chaldron weighs only 28 cwt. The former contains 68, the latter 36 Winchester bushels. Since the duty on coals water-borne ceased the account of the quantities shipped has been kept with less correctness.

Coals Shipped from the Port of Newcastle from 1849 to 1857.

Year.	Coastwise.	Foreign.	Year.	Coastwise.	Foreign.
	Tons.	Tons.		Tons.	Tons.
1849	2,127,558	778,465	1854	2,138,311	1,345,456
1850	2,252,293	1,007,716	1855	2,014,760	1,417,640
1851	2,049,846	1,001,939	1856	1,942,843	1,649,788
1852	2,157,273	1,057,463	1857	2,082,001	1,773,363
1853	2,131,417	1,032,566			

The number and tonnage of vessels registered as belonging to the port of Newcastle on 31st December 1856 were,—Sailing-vessels under 50 tons, 110; tonnage, 3083; above 50 tons, 452; tonnage, 124,830: steam-vessels under 50 tons, 81; tonnage, 1364: above 50 tons, 23; tonnage, 7621. During 1856 there entered and cleared at the port in the coasting trade,—Sailing-vessels, inwards, 2172; tonnage, 179,281: foreign, outwards, 9860; tonnage, 1,262,076: steam-vessels; inwards, 525; tonnage, 112,325: outwards, 782; tonnage, 196,713. In the colonial trade,—Sailing-vessels, inwards, 70; tonnage, 17,040: outwards, 151; tonnage, 59,019: steam-vessels, outwards, 1; tonnage, 16. In the foreign trade,—Sailing-vessels, inwards, 3816; tonnage, 593,339: outwards, 6697; tonnage, 1,217,689: steam vessels, inwards, 103; tonnage, 33,452: outwards, 119; tonnage, 31,341.

The export of lead from Newcastle, although much inferior in importance to that of coal, is of still greater anti-

quity. The lead mines are situated in the mountainous districts in the west of Northumberland and Durham, and in the adjacent parts of Cumberland, from which the produce is conveyed to Newcastle for shipment. The discovery of the mines of Cumberland in the reign of Henry I. is noticed in the Chronicle of Robert de Monte; and those of Durham were probably known at as early a period. The latter were granted by King Stephen to his nephew Hugh Pudsey, Bishop of Durham. The Cumberland mines were gradually extended into Northumberland; and in the reign of Richard I. by much the more valuable portion was in the latter county. In the earliest records the mines both of Cumberland and Durham are described, not as lead but as silver mines, from the abundance of that precious metal which they contained. Those of Cumberland were let to the royal moneyers at Newcastle and Carlisle, and those of Durham probably supplied the mint which pertained to that episcopate. The pipe rolls of Cumberland and Northumberland afford several instances of the transport of lead from the former county for export from Newcastle in the reign of Henry II. The productiveness of these mines continues undiminished; and large quantities are yearly exported from Newcastle, both in pigs and in a manufactured state. The manufactures carried on here include patent shot, and all other preparations of lead, whether for pigments or otherwise.

The manufacture of glass was first introduced into England by emigrants from Germany, who established themselves in the neighbourhood of Newcastle in the reign of Queen Elizabeth. The trade has continued to flourish ever since, and is now extensively carried on in all its branches—bottle, crown, sheet, and plate glass.

Works for smelting iron have been established in this district for many years, but these have been multiplied to a great extent within a short period. Various branches of the iron manufacture are also carried on, including three very extensive establishments for building locomotive engines; one of them set on foot by the late George Stevenson, father of the locomotive system, and now conducted by his son, Robert Stevenson, C.E. The building of iron ships has also been recently introduced on a very extensive scale. Since the year 1816 a most important business has arisen in the neighbourhood of Newcastle, namely, the production of crystals of soda and mineral alkali by the decomposition of common salt. Besides these, there are manufactures of paper of all descriptions, and mills for the crushing of linseed; and the manufactories of coppers, coal-pitch, spirits of tar, varnishes, soda, aquafortis, whiting, glue, vinegar, and soap, are numerous and extensive.

The imports are various, but the principal articles are corn, wine, spirits, fruits, sugar, tobacco, tea, coffee, butter, cheese, tallow, hides, oak-bark, rags, flax, hemp, linen yarn, mahogany, deals and other timber, spars, masts, cordage, tar, iron, and what is necessary for the equipment of shipping. This view of exports and imports accounts for the number of vessels which have entered this port in successive years from foreign countries.

Newcastle occupies the site of the Roman fortress of *Ancient Pons Ælii*, one of the stations on the Wall of Hadrian, which traversed the island from the Tyne to the Solway Firth. In the immediate vicinity the Saxon kings had a villa or occasional residence, called *Ad Murum*, celebrated, according to Beda, for the baptism within its walls of two royal converts—Sigebert, King of the East Saxons, and Pæda, the son of Penda, King of Mercia. At the period of the Norman conquest the Roman station was known as *Monkchester*, having probably been used as a place of refuge by the brethren of some of the numerous monastic establishments which existed in the neighbourhood prior to their destruction by the Danes, towards the close of the ninth century. The castle, which gives name to the pre-

Newcastle-upon-Tyne. sent town, was built by Robert, the eldest son of William the Conqueror, on his return from a hostile expedition into Scotland, A.D. 1080. William Rufus is said to have fostered the growth of the infant community, as well by grants of privileges as by pecuniary aid. The particulars of these concessions rest on the authority of the metrical annalist Hardyng, a comparatively recent historian; but the general truth of his narrative is confirmed by the ascertained position of Newcastle in the succeeding reign. The "Laws and Customs of Newcastle" under Henry I. bespeak the advanced maturity of the borough, and the amount of royal favour which it must have experienced. In the reign of Stephen, Newcastle, with the rest of Northumberland, was enjoyed in succession by the Earls Henry and William, the son and grandson of David I., King of Scotland, but was taken from the latter by Henry II. on his accession to the crown of England. King John granted several charters to the burgesses; amongst others, one conferring the right of holding the town in fee-farm, instead of at the will of the crown. Henry III. further extended their immunities by authorizing the election of a mayor out of their own body, who should preside over them, instead of a provost, as heretofore, appointed by the crown. The enfranchisement of the borough from the dominion of the sheriff of Northumberland, and the liberty of electing a sheriff of their own, was conceded to them by Henry IV. Several additional immunities were granted by successive charters, all of which were, in the reign of Elizabeth, condensed and confirmed by what was known then as the "Great Charter;" and that, being afterwards slightly changed in the reign of James I., continued till the passing of the existing law in 1835. By that law the town has been divided into eight wards for the purposes of that act, and has now fourteen aldermen, forty-two councillors, a mayor, and sheriff, with justices of the peace, nominated by the crown. It returns two members to Parliament.

The revenue of the corporation is very large, amounting in 1856 to L.82,000, arising from dues on coal and cinders, rents of property, tolls, &c.

Docks, &c. The corporation were, up to 1850, conservators of the Tyne, but in that year they were superseded by a commission composed of members from Newcastle, North and South Shields, Gateshead, &c. By the Tyne Improvement Act, which received the royal assent on the 15th July 1850, the conservancy of the River Tyne is transferred from the corporation of Newcastle to the "Tyne Improvement Commissioners." Those commissioners are in number 18,—viz., 4 life commissioners named in the act, and 6 elected annually by the Newcastle council, 3 by the Tynemouth council, 3 by South Shields council, and 2 by Gateshead council. The elections of river commissioners by the respective councils takes place on the 9th November in each year. By the Tyne Improvement Act 1852, additional powers are vested in the commissioners; and they are, by that act, authorized to construct a dock at Hayhole, to be called the Northumberland dock, and to form piers at the mouth of the river. The Northumberland dock has since been completed, and the two piers are in a state of considerable forwardness. By the Tyne Improvement Act 1857, the commissioners are also authorized to construct a deep-water dock at Coble Dean, communicating by a junction with the Northumberland dock. Besides the corporation there are many guilds or companies, having chartered privileges, and halls for their assembling. There are the "Twelve Mysteries," founded between the years 1215 and 1621; the "Fifteen By-Trades," founded between 1426 and 1626; and the various companies, eight in number, created at different periods, like the others, between the years 1454 and 1675. These companies choose annually sixty-nine stewards, out of which number a body of nine is nominated, called the Herbage Committee, whose duty it is to superintend the improve-

ment and enforce the regulations respecting the free commons, of 1200 acres, upon which the burgesses have the privilege of pasturing two cows each (and a free pasturage is thus afforded to 700 cows), and also to watch over the interests of the freemen, and of their respective fraternities. They have a revenue of about L.900, derived from ground-rents, way-leaves, and other sources.

Newcastle being a county of itself, the courts of assize ^{Town and} _{county} ^{and} _{courts.} *nisi prius* are held thrice a year at the guildhall at the Exchange. Those for Northumberland, in the county-courts at the Castle Garth, are held at the same time. There are also some inferior courts of justice held, such as the mayor's court, in which only free burgesses or their widows are sued, and in which are tried all cases relating to real or personal actions to any amount arising within the town; the sheriff's court, in which all actions are brought as in the mayor's court, but with this distinction, that they may be instituted against all other persons than free burgesses; the court of conscience, to determine all debts or actions not exceeding in amount forty shillings, which extends to all persons residing within the liberties of the town; and the court of guild, the chief business of which now is the admission of persons to their freedom, whether they are entitled to it by birth, or by an apprenticeship during seven years. Besides these, a court of admiralty is occasionally held, the principal duties of which consist in preventing injury from being done to the river or to the salmon fishery.

The population of Newcastle has advanced in nearly the same proportion as that of the other towns of the kingdom. Population. In 1801 it amounted to 28,366, in 1811 to 27,587, in 1821 to 35,181, in 1831 to 42,760, in 1841 to 69,430, and in 1851 to 87,784. But each of these accounts is materially deficient, owing to their exhibiting only the number of inhabitants within the limits of the burgh; and does not include those of its populous suburbs. In 1851 Gateshead alone had 25,568 inhabitants. Annual rental 1857, Newcastle, L.351,408; Gateshead, L.75,749.

The public buildings for religious purposes are numerous. Those of the Established church claim the first attention. Of these, the mother church of St Nicholas is probably the oldest, and certainly the most striking. It was founded in the year 1091, by Osmond, Bishop of Salisbury, and placed under the jurisdiction of the bishop of Carlisle. The edifice was burned in 1210, and the present structure finished in 1359. The interior of the church is 242 feet; and on entering it by the great western door, the spectator is struck with mingled impressions of delight and solemnity, from the general and noble effect produced by the view. Some considerable improvements in the arrangement of the pews made in 1783 have adapted it for accommodating a congregation of more than 1200 persons. The organ is a remarkably fine instrument. The framework is mahogany, and the two pillars in front are magnificent; the centre is surmounted by the figures of two recumbent angels, and the compartments of the front are embellished with a variety of richly-gilt pipes. Several fine marble monuments have recently been erected on this edifice. A public library is attached to this church, formed by donations at different periods since the year 1661, but principally by Dr Tomlinson.

St John's church is an ancient structure, and supposed to have been built in the latter end of the thirteenth century; but it has since been enlarged and beautified at different periods. The great eastern window contains some curious ancient specimens of stained glass. By the erection of some new galleries and other arrangements of pews, it has been made capable of seating, including scholars in the aisles, more than 1400 persons. It has a square steeple with four pinnacles, a clock and six bells, with a large burying-ground adjoining.

Newcastle-upon-Tyne. St Andrew's church is said to have been built by David king of Scotland, who died in 1153. It still exhibits some specimens of Anglo-Norman architecture, though many alterations have been made at different periods. Being near the town wall, it suffered much during the siege of 1644, and was long afterwards closed. It is furnished with a new organ, and the interior so arranged as to accommodate 1300 hearers, besides 200 children. Near to it is the burying-ground, which, by the removal of some houses in 1824, is laid open to public view, and handsomely surrounded by palisades.

All-Saints' church is a modern structure, having been erected between the years 1786 and 1796, at an expense of £27,000, raised by an assessment upon the owners of houses in the parish. It has a stately Doric portico at the entrance, from which there rises an elegant spire to the height of 202 feet from the ground. It has a fine set of bells and a clock. It contains a spacious gallery, and the whole seat-room will accommodate near 1200 persons, and 270 children of the charity schools, who have seats in the gallery. This building was erected on the site of an ancient church which existed before the year 1284, but which was considerably larger, and capable of containing 2000 persons.

St Ann's church is, properly speaking, a chapel of ease to the parish of All-Saints. It was erected in 1768, on the foundation of an ancient building, at the expense of the corporation. It has a large school attached to it, in which boys are instructed in reading, writing, and arithmetic, on very cheap terms. The church has seat-room for about 500 persons.

St Thomas' church is a chapel of ease to the parish of St Nicholas. It was begun in 1828, and finished in 1830. It is an elegant structure, built in the early English style. The church is 135 feet in length and 63 feet in breadth, and has a tower 138 feet in height. It can accommodate from 1000 to 1100 persons. In the suburb or town of Gateshead is the church of St Mary, a new steeple to which was built on an old foundation in 1740. Its chief ornament is an elegant window of stained glass in the southern transept, which was presented to it in 1824. There is seat-room for 800 persons, including that for the charity children. Among the other churches are St Peter's, Oxford Street, and St Paul's, Arthur's Hill. This latter has been purchased by the Independents.

The places of worship for the various classes of dissenters from the Established church are numerous. From the vicinity to Scotland, the adherents of the Presbyterian form of worship are the greatest in number, occupying nine meeting-houses, most of them being of the Scotch kirk, and others secessions from it. The next largest portion of worshippers are the Wesleyan Methodists of the new and old connection, who have six chapels, one of them the largest place of worship in the town. The Independents occupy three chapels, the Baptists three, the Roman Catholics two, and the following persuasions,—viz., the Quakers, the Glass-ites, the Unitarians, and the Swedenborgians,—one each.

To the enterprise of Mr Richard Grainger the inhabitants of Newcastle owe the creation of almost a new town, built in a style of architectural beauty not inferior to any in the kingdom. After having built Eldon Square, Blackett Street, and several others of minor importance, Mr Grainger's first exertions, in an embellished style of architecture, were made on a large piece of ground adjoining the Leazes. Upon this he erected a parallelogram, consisting of upwards of fifty houses, all faced with polished stone, and of great elegance of design, and some of them of large dimensions. This undertaking was carried through by him at the same time that a spacious and splendid arcade was constructed in the centre of the town. The next attempt of this individual was more gigantic, and incurred an expenditure of half a million sterling. There existed in the

very centre of the town a large piece of ground, about thirteen acres, which had originally been the gardens of the Grey Friars, and of a convent of Benedictine nuns. This completely cut off the communication between the opposite sides of the town, except by circuitous streets, and was partly occupied by stables, cow-sheds, and other nuisances. Mr Grainger conceived the idea of covering this extensive piece of ground with houses and markets of elegant construction. The purchase of the ground was effected, and the work begun, in the summer of 1834. This extraordinary undertaking consists of seven streets, some of them 80 feet broad, and all of stone, and highly embellished; besides a butcher market and a vegetable market, which alone occupy a space of more than two acres, and are entirely covered in. The butcher market consists of four avenues, 19 feet 4 inches wide, 27 feet high, and extending in length 338 feet. The vegetable market is connected with the butcher market, and consists of one stupendous hall, 318 feet long, 57 feet wide, and upwards of 40 feet high. A new theatre of great architectural beauty, a chapel for the Methodists of the new connection, a new dispensary, and a church, are also included in the plan. At the top of the principal street, named Grey Street, is a column 150 feet high, surmounted by a statue of Earl Grey. This elegant memorial is from a design by Messrs John and Benjamin Green of Newcastle, and the statue is by Bailey of London. The cost was defrayed by public subscription. Recently a large and massive building has been erected for the jail and house of correction, which cost £49,000.

Newcastle is as well supplied with those institutions which tend to the acquisition and diffusion of knowledge as any place of its extent in the kingdom. The Literary and Philosophical Society was founded in 1793. Its objects were—the discussion of the several branches of polite literature, and making inquiries into the situation and properties of the mineral productions of the neighbourhood, with the elucidation of the sciences applicable to commerce, antiquities, local history, biography, nautical inquiry, and other subjects. A new institution for delivering lectures has been united with it since 1802. A library, of more than 12,000 volumes, has been collected, and a valuable apparatus purchased for the illustration of chemistry and other branches of physics. The usefulness of this society has recently been greatly increased by the reduction of the annual subscription from £2, 2s. to £1, 1s., in consequence of a munificent donation to its funds by a spirited individual (Robert Stevenson, Esq., M.P.) The Natural History Society has erected an elegant building, which contains a museum of very great value. The published transactions of this society have raised the character of its members to a high rank in that science. The Newcastle Antiquarian Society hold their meetings in the old castle.

There is also an establishment recently formed, called "The Literary, Scientific, and Mechanical Institution," of which young persons may become members, and attend classes appointed for drawing, mathematics, chemistry, and the languages, at a very small expense. This society is also gradually forming a library, and various collections to assist in science and in art. There are likewise several subscription-rooms for newspapers,—especially good ones at the Exchange, Sandhill, and Central Exchange, Grey Street.

There is a well-endowed royal free grammar school, in which Greek and Latin were intended to be taught gratuitously; but a small fee is now paid by the scholars. It has access to some exhibitions at Lincoln College, Oxford. In several other schools many boys and girls are taught on the Lancasterian and Madras plans; and most of the churches and chapels have schools connected with them.

Newcome.

The institutions for benevolent purposes are numerous, of which the most prominent are Jesus' hospital, which provides for fifty old persons; Blackett, and the two Davidson's hospitals, in all for eighteen poor widows of clergymen or merchants; the Keelman's hospital, formed by that class of persons for the relief of their destitute, and chiefly maintained by a duty of one farthing per chaldron on all coals exported from the River Tyne; and the hospitals of St Mary Magdalen and of the Virgin Mary, the former for a master and three, and the latter a master and eight poor brethren.

The establishments for administering relief to the diseased or infirm poor are,—the infirmary, to which is now annexed a lock hospital, and which extends relief to the sick and lame poor of the counties of Newcastle, Durham, and Northumberland; the average annual number of in-patients being 800, and of out-patients 700; the dispensary, founded in 1777, supported by voluntary contributions, the object being the administration of medical and surgical aid to all diseased applicants, and the promotion of vaccine inoculation; the house of recovery, for the reception of persons afflicted with febrile diseases; the lunatic asylum, for thirty-eight males and the same number of females; the lying-in hospital, for poor pregnant women; the eye infirmary, and St Luke's hospital.

Markets,
&c.

The markets are well supplied with provisions of all kinds; and the market for corn is one of the largest in the north of England. Water is abundantly supplied by the Water Company, from resources and reservoirs at Whittle Dean, 12 miles W. of Newcastle. There are no less than twelve public fountains, here called *pants*, in different parts of the town, but on account of the height of the reservoirs above the town, they are seldom now required, the pressure being sufficient; the fire-engines are under good regulation. There are companies for insurance against fire, as well as for ship and life risks. The town is well watched and lighted with gas.

The places of amusement are not numerous; the most prominent being the theatre-royal. The former house was opened in 1788, and was pulled down in 1836 to make way for the building of Grey Street. The new theatre, which is a structure of great beauty, was opened in February 1837. The assembly-rooms, built in 1766, are commodiously planned, having a ball-room 94 feet by 36, with a music gallery; adjoining are card-rooms, a room for private assemblies, and on the lower story is a supper-room, in which 460 individuals have been accommodated at the same time. There is a music hall appropriately fitted up, with the requisite auxiliary apartments.

The communication between Newcastle and the western coast is greatly facilitated by the Newcastle and Carlisle Railway, and to the north by the North British Railway. (J. H.)

NEWCOME, WILLIAM, Archbishop of Armagh, a learned divine, was born in Bedfordshire in 1729. Having entered the university of Oxford, he was first a student of Pembroke College, and afterwards a fellow and tutor of Hertford College. His rise to honour and preferment was sudden and rapid. The degree of D.D. was conferred upon him in 1765; in the same year he became chaplain to the lord-lieutenant of Ireland; and in 1766 he was promoted to the bishopric of Dromore. All the while Newcome was closely directing his attention to biblical criticism, and was carefully maturing his views preparatory to publishing them. At length the results of his studies began to appear in quick succession. He published, among other works, *The Harmony of the Gospels*, in 1778; *The Duration of our Lord's Ministry particularly considered*, in 1780; *Observations on our Lord's Conduct as a Divine Instructor*, in 1782; *An Historical View of the English Biblical Translations*, in 1792; and *An Attempt towards*

revising our English Translation of the Greek Scriptures, in 1796. Meanwhile, the author, after having been successively translated to the sees of Ossory and Waterford, had been installed in the archbishopric of Armagh in 1795. His death took place in 1800.

Newfound
land.

NEW ENGLAND, a name given to the north-eastern portion of the United States of North America, comprising the states of Maine, New Hampshire, Vermont, Massachusetts, Rhode Island, and Connecticut. (See UNITED STATES.)

NEWENT, a market-town of England, county of Gloucester, 8 miles N.W. of the town of that name, and 110 W. by N. of London. It consists of three irregular streets, and has a large old parish church, with a lofty spire, 2 dissenting churches, and a national school. Pop. (1851) 1547.

NEW FOREST. See HAMPSHIRE.

NEWFOUNDLAND, an island belonging to Great Britain, in the N. Atlantic Ocean, off the E. coast of North America, and forming the most of the eastern boundary of the Gulf of St Lawrence. It lies between N. Lat. 46. 38. and 51. 37., W. Long. 52. 44. and 59. 31.; and is separated from Labrador by the Straits of Belleisle, about 12 miles broad; and on the S.W. it approaches within 70 miles of North Point, in Cape Breton Island. Its form is generally triangular, but extremely irregular. Its area is about 36,000 square miles, and its coast line is estimated at nearly 1000 miles in length.

This vast island reposes upon an immense bank, a continuation of which has been observed all the way to Nova Scotia. It is apparently a mass of solid rock, having a very wild and rugged appearance from the sea, and being anything but inviting.

On its south-eastern quarter Newfoundland is formed into a peninsula of about 80 miles in length, by from 15 to 60 in breadth; the isthmus which unites it with the mainland being not more than 4 miles in breadth. This peninsula is called Avalon. To the N. of it, and on the east side of the island, lies Trinity Bay, which is separated from that of Bonavista by a narrow neck of land, the point of which is Cape Bonavista. A long neck of land also divides Trinity Bay from Conception Bay on the northern side of Avalon. This bay ranks as the first district in Newfoundland, as well on account of the spirit and enterprise of the inhabitants who people its shores, as from its natural advantages of large harbours, coves, and the like. The scenery on this part of the coast is majestic, wild, and calculated to strike the beholder with awe. About 20 miles from Cape St Francis, the eastern boundary of Conception, are the bay and harbour of St John's, the capital of Newfoundland. A succession of bays indent the coast all round the peninsula of Avalon, the principal of which are—Trepassey Bay, St Mary's Bay, and Placentia Bay. The last, about 60 miles deep and 45 broad, lies between Cape St Mary and Cape Rouge, and contains several harbours and islands. It is separated from Fortune Bay by one of those long and narrow necks of land which are so common in the island. Fortune Bay is from 60 to 70 miles deep, and from 20 to 30 broad, receiving many rivers from the island lakes, and containing numerous harbours, the principal of which is Fortune Harbour, on the eastern side. St Pierre and Miquelon Islets are situated at the mouth of Fortune Bay. They were ceded to France in the year 1814, and the former contains a harbour which is the rendezvous of the French shipping, and the residence of the governor. From this point, all along the south side of Newfoundland to Cape Ray, which forms the N.E. entrance of the Gulf of St Lawrence, there are numerous bays, but none of sufficient size or importance to require particular description. On the western side, formed by Cape Anguille and Cape St George, is the Bay of St George, a large and deep inlet of the sea, into which several rivers, emerging from lakes in the interior, empty themselves. Further to the

Surface of
the coun-
try.

Newfoundland. north is the Bay of Islands, formed by three arms, into which several rivers discharge their waters. One of these, called the Humber, is the most considerable yet discovered, its course having been traced for 114 miles to the north-westward, where it issues from a lake between 50 and 60 miles in length. As its name would indicate, this bay contains a number of islands, but none of any particular consequence. The next large indentation of the sea on the western side of Newfoundland is Bonne Bay, which has also rivers communicating with the lakes in the interior. The next bay is called Ingornachois Bay, which contains two harbours; and to the north of it is St John's Bay, which receives the waters of Castor's River. Along the Straits of Belleisle, which separate Newfoundland from the coast of Labrador, are a few inconsiderable inlets; but beyond Cape Norman, the N.W. point of the island, is a large bay called Pistolet Bay; and further to the S. is Hare Bay, a deep gulf, the bottom of which intersects the island for two-thirds of its breadth at this point, branching off into innumerable bays and coves, sheltered by lofty hills. From this haven to White Bay, a very large inlet of the sea on the eastern side of the island, and thence to Cape St John, the coast is indented at short distances by commodious and much-frequented harbours. The Bay of Notre Dame and the Bay of Exploits are of great extent, and contain a vast number of islands, together with a thriving settlement called Twillingate. The River Exploits is about 70 miles long, but its navigation is obstructed by rapids, some of which have a velocity of nearly 10 miles an hour. This river connects the Red Indian Lake, a large sheet of water in the interior, with the Atlantic. From Cape St John to Cape Freels the coast is a continuation of ledges, shallows, islands, and rocks, but affords excellent fishing-grounds. Bonavista Bay contains several islands, and is itself indented by a number of small inlets and harbours. To the south of it is Catalina Bay, containing Ragged Harbour, which completes the circuit of the island.

After the exterior aspect of Newfoundland has been described, the interior comes naturally to be noticed. But this has as yet been very imperfectly explored. In 1823 a Mr Cormack succeeded in traversing its breadth from Conception Bay on the east to St George's Bay on the west; and from his account it appears, that this portion of it at least is much intersected with lakes and rivers, but poorly wooded, and of a rocky and barren soil. In this respect the island differs greatly from the other North American colonies, producing little timber but what is dwarf and stunted, except on the margins of bays and rivers, where spruce, birch, and poplar sometimes grow to a considerable size. Several high hills occur near the centre of the island, and the inland country is represented as generally undulating, so that lakes, rocks, marshes, and occasional elevations, with little or no vegetation, constitute its characteristic features. The geology of Newfoundland is nearly the same as that of the coast of Labrador. The prevailing formation is granite; but porphyry, syenite, trap, gneiss, mica, clay-slate, and other strata are also found. The island, it appears, abounds with minerals of various sorts. Coal and lime have been wrought in more than one part with some success; and there is little doubt as to the existence of copper, iron, and other mines, but it is not likely that they are very productive. There are excellent gypsum quarries near Cape Ray, and there is also a quantity of the mineral called marcasite, or iron pyrites, which the early discoverers mistook for real gold.

Climate. The climate, though severe, is healthy; the rate of mortality is below that of any part of the continent of America; and many of the inhabitants attain to a great age. The winter lasts from the beginning of December to the middle of April; and the most intense cold occurs in the months of January and February. During this period, owing to the

clearness of the atmosphere, the brightness of the stars and northern lights have an exceedingly beautiful appearance. The snow does not lie long on the ground, and the cold is not so great as in Canada. The summer is short, but mild and pleasant; though the heat is sometimes great in that season.

The most remarkable feature connected with Newfoundland is the fogs which prevail on its coasts. Those of the Gulf of St Lawrence are attributed to the coldness of the gulf-waters, which is supposed to be permanent a few feet below the surface, as well as at great depths. The fogs on the banks of Newfoundland are undoubtedly chiefly due to the meeting, in that point, of the cold air transported along with the polar current with the warm atmosphere over the gulf-stream. On the great bank the surface of the water is many degrees colder than it is in the neighbouring sea, and much less than that of the Gulf-stream, which is within a short distance of it.

The soil of Newfoundland in the vicinity of the rivers and lakes is generally rich and fertile, but it is covered in many places with a thick coating of moss; and in the eastern and southern parts of the island there are many tracts which are very sterile, and can only be made productive by constant manuring. The amount of cultivated land in the island, according to the census taken in 1845, was 82,259 acres.

The most valuable vegetable productions are potatoes and cabbages; and, next to these, turnips, carrots, parsnips, radishes, and other garden roots, yield the most abundant crops. There were in the island, according to the census of 1845, 2409 horses, 8135 horned cattle, 5750 sheep, and 5791 goats. Cariboo deer, beavers, foxes, wolves, and bears abound; as well as the well-known Newfoundland dog, the true breed of which has become very scarce. Besides the great staple of the island, fish, which is here understood to mean cod, the numerous large and small sheets of water abound in divers kinds of excellent trout and eels of a great size; and lobsters, lance, herrings, mackerel, and salmon, are in great abundance; plaice, sole, halibut, and thornback, are likewise found on the coast. The capelin arrives periodically in such immense shoals as to change the colour of the sea. Herrings likewise arrive during spring and autumn in prodigious numbers. As a product of the coast may be mentioned kelp, which, with other sea-weed, is used as manure.

The importance of this colony has exclusively arisen from its fisheries. The different settlements are scattered principally on the shores of the eastern and southern sides of the island, but especially on the former. They are generally formed at the heads of the bays, particularly Conception Bay, thence to St John's, and southward to Cape Race. The principal are, besides St John's, the Bay of Bulls, Brigus, Cape Broyle Harbour, Ferryland, Fermoyle, and Renowes. St John's, the capital of the island, is a place of considerable strength, situated about 70 miles to the N. of Cape Race; N. Lat. 47. 35., W. Long. 52. 48. The harbour is one of the best in Newfoundland, being formed between two mountains, the eastern points of which leave an entrance, called the Narrows. This is the only assailable part, but it is so well defended that any vessel attempting to force an entrance would inevitably be destroyed. There is about 12 fathoms of water in the middle of the channel, with tolerably good anchorage-ground. The most lofty perpendicular precipices rise to an amazing height upon the north side, and the southern shore appears less striking in its altitude, only from a comparison with the opposite rocks. There is a light shown every night on the left side of the entrance, where there are also a small battery and a signal-post. Other batteries of greater strength appear towering above the rocky eminences towards the north. At about two-thirds of the distance between the entrance and

Newfound-
land.

what may properly be termed the harbour itself, there is a dangerous shelf called the Pancake, opposite the Chain Rock, so called from a chain which, in time of war, extends across the strait at that place, to prevent the admission of any hostile fleet. There are other fortifications besides those already noticed, planted upon the heights around the town, so as to render St John's perfectly secure against any sudden attack. Fort Townshend is situated immediately over the town, and is the usual residence of the governor. Forts Amherst and William are more to the north; and there is also a small battery perched on the top of a single pyramidal mount, called the Crow's Nest. The town itself consists chiefly of one long straggling street, extending nearly parallel to the shore on the north side of the port, from which branch out several narrow lines of houses, that can only be called lanes. The houses are chiefly built of wood, although diversified by some of brick and a few of stone; but they are somewhat irregularly placed, although the town has been much improved in this respect since the fire of 1846. The principal feature of the town consists in its multitude of wharves and fishing stages, which entirely line the shore. The government wharf is a fine broad quay, open to the accommodation of the public. St John's has repeatedly and severely suffered from fires. In 1815 a great amount of property was destroyed by a visitation of this sort. Other conflagrations took place in 1817 and 1818; and in 1846 the town was again almost destroyed by fire. There are nine places of public worship of various denominations at St John's, several school-houses, and numerous literary, scientific, and benevolent institutions. The town has a brewery, a distillery, a flour-mill, and a foundry. The number of vessels that entered the port in 1851 was 842, and their tonnage 103,016. Those that cleared in the same year were 703, and their tonnage 91,191. The trade of the place consists principally in the export of dried fish, and of seal, whale, and cod oil; and in the import of bread, flour, tea, sugar, and other necessaries of life. The resident population is about 19,000, and the fishermen amount to about 6000.

The following table shows the quantities of dried cod and seal-oil exported from Newfoundland for each year from 1851 to 1855, a quintal of fish being 100 lb. :—

Years.	Dried cod.	Seal-oil.
1851	1,017,152 quintals.	6968 tons.
1852	972,921 "	7333 "
1853	922,718 "	8137 "
1854	774,117 "	5667 "
1855	1,107,388 "	3760 "

The number of vessels that entered in 1855 was 1185, and their tonnage 150,603; those that cleared were 1017, and their tonnage 137,513. The total value of the imports in the same year was L.1,152,804; and that of the exports L.1,142,212. The government of the island is in the hands of a lieutenant-governor, with a yearly salary of L.3000, assisted by an executive council, not exceeding seven in number, appointed by himself. The legislature consists of a legislative council, above ten and below fifteen in number, appointed by the Crown, and a house of assembly of thirty members, elected by the people. The constitution received its present form in 1854, and at the same time the system of responsible government was established. The public revenue in 1855 was L.126,449, and the expenditure L.120,926. The public debt of the colony in the same year amounted to a total of L.150,000. The judicial establishments of the island comprise a supreme court, composed of one chief and two assistant judges; and three circuit-courts for the Northern, Central, and Southern divisions of the island. No religious establishment is supported by the public funds, but the bishop of Newfoundland receives a salary of L.300 a-year from the

Newfound-
land.

British Treasury, the remainder of the provision for the episcopate being supplied by the Society for the Propagation of the Gospel. There were in 1855 forty ministers of the Protestant Episcopal church in Newfoundland and the coast of Labrador, and sixty-six churches. The Roman Catholics, in the same year, had forty-nine churches; the Wesleyans thirty-seven churches, forty preaching stations, and thirteen missionaries; and the Established Church of Scotland, the Free Church, and the Congregationalists, had each a place of worship at St John's. A considerable part of the public money is devoted to the purposes of education; and this sum amounted in 1855 to L.8871. The number of schools aided by these grants was 219, and the number of scholars 13,602. The sum expended for benevolent purposes in the same year was L.17,787; and the principal charitable institutions are an hospital and lunatic asylum at St John's.

When Newfoundland was first visited it was found to contain two distinct races of aborigines; the one termed Red Indians, and the other Esquimaux. Both are now almost extinct; the former, it is supposed, is entirely so, as deadly feuds were waged between them and the early settlers. Besides, the Mic-mac Indians, who were introduced into the island from Cape Breton and Nova Scotia, carried on with the Red Indians an exterminating war, which proved far more fatal to them than the hostilities of the Europeans. A female of this tribe was captured in 1818, and from her a vocabulary of their language was obtained.

Without dwelling upon the tradition which represents Newfoundland as having been settled at a very early period by one Biron, a sea-king or pirate of Iceland, we have authentic evidence of its re-discovery by John Cabot, on the 24th June 1497. Sailing under the commission of Henry VII. in these seas, he descried a headland, which, as a lucky omen, he called Bonavista, a name which it still retains. It was at that time inhabited by native Indians, three of whom he brought home, clothed in skins, and speaking a language which no person understood. It was afterwards visited by navigators from France and Portugal, who, reporting favourably of the abundance and excellency of its cod fishery, European fishermen were soon attracted to its coasts. In 1536 an English vessel attempted to winter upon the island, but the crew nearly perished from starvation. Not deterred by this failure, however, nor by that of a former attempt, Sir Humphrey Gilbert, in 1583, landed on the island with 200 followers, and, under a patent of Queen Elizabeth, took quiet possession of the country. Being, however, desirous of prosecuting his discoveries, his crews became disaffected, and, having separated into two parties, one of them returned home. Most of those who followed him were lost in a gale of wind off the Sable Island, and the remainder perished, along with himself, on their voyage homewards. Subsequent attempts were made to explore and settle Newfoundland, but it was not until the year 1623 that the first colony was established under Sir George Calvert, afterwards Lord Baltimore. His son was made governor of the colony, which he named Avalon, and soon afterwards proceeding thither himself, it increased and flourished under his auspices. Other individuals obtained grants of land; and, about the year 1654, fifteen settlements, comprehending 300 families, had been made on the island, notwithstanding the constant bickerings between the English and French, the latter having established a colony at Placentia. On the breaking out of the war after the accession of William III., these assumed a more serious character, and, after various recriminations, St John's was compelled to surrender to the French in 1696. The captors set fire to the fort and town, and destroyed most of the British settlements. To repair these losses, our government despatched a squadron; but

New
Granada
||
New
Hampshire.

the cowardice of one commander, and the ignorance of another, frustrated the design. The re-establishment of peace put an end to hostilities for the time; but they were resumed in 1702, during which year several of the French settlements were destroyed, and a great many fishing-boats were burned or captured. In the following year an expedition miscarried, and this circumstance encouraged the French to attempt the conquest of the whole island in 1705. For this purpose 500 men were despatched from Canada to the assistance of the garrison of Placentia, who, though repulsed from St John's, extended their ravages over the different settlements as far as Bonavista. In the year 1708 the French completely demolished the town of St John's; and, shortly afterwards, Carbonia, the only settlement of consequence remaining in our hands, was partially destroyed. From this time until the conclusion of the peace of Utrecht, the French remained in quiet possession of Newfoundland; but, by this treaty, the island, with all the adjacent ones, was declared to belong to Great Britain, the French being only allowed the use of the two islets of St Pierre and Miquelon. The revolutionary war in America occasioned fresh disputes as to the right of fishing upon the banks of Newfoundland. The New Englanders had hitherto enjoyed the right of taking fish, and on this being resisted, they retaliated, by refusing to supply the colony with many articles of provision upon which it depended. This dispute was settled by the treaty of Versailles in 1783, by which it was stipulated that the inhabitants of the United States should have liberty to take fish of every kind on the coast of Newfoundland, but not to dry or cure their fish upon the island. Pop. (1845) 96,864; (1850) estimated at more than 100,000.

NEW GRANADA. See GRANADA, *New*.

NEW HAMPSHIRE, one of the United States of North America, is bounded on the N. by Canada, E. and S.E. by Maine and the Atlantic Ocean, S. by Massachusetts, and W. by Vermont. It lies between 42. 41. and 45. 25. N. Lat., and between 70. 40. and 72. 35. W. Long.; extending in length about 185 miles, whilst its average breadth is about 50 miles, and its area is computed at 9280 miles. On the map its shape nearly resembles a wedge inserted between the states of Maine and Vermont, and having Massachusetts for its base. The line of coast is indented with small inlets of the sea, and skirted by a narrow sandy plain. At no great distance the country swells into a mountainous region, and New Hampshire has justly been called the "State of Hills," and also the "Granite State." Mount Washington, the highest peak of the White Mountain range, has a height of 6226 feet; and is thus, with the exception of Mount Mitchell, in North Carolina, the highest mountain in the Union E. of the Mississippi. Between the Merrimack and the Connecticut are situated many considerable mountains; the names of the principal heights being Monadnock, 3718 feet high; Kearsarge, 3067 feet; Car's Mountain, 1381 feet; and Moosehillock, 4636 feet. As a whole, the physiognomy of New Hampshire is bold and prominent, and, although rugged, often sublime in the highest degree. The mountains of the state are in the centre, with a zone of finely-diversified hill and dale country around, the hills consisting generally of stony and moist land, and affording excellent pasturage. The geological structure of the mountains of New Hampshire consists principally of granite and mica slate; the former predominating among the White Mountains, and the latter among the elevations farther to the S. The mineral resources of the state are considerable. Iron has been found in great abundance in many parts of the country; and there are also mines of copper, tin, lead, and zinc. Granite is more abundant here than in any of the other states; and fine marble has been found in considerable quantities. The general slope of the state is from N. to S., and in

New
Hampshire.

that direction the most of the rivers flow. Of these the principal are—the Connecticut, which forms the boundary between this state and that of Vermont; the Merrimack, flowing through the middle of the state; the Piscataqua, in the S.E.; and the Androscoggin, which flows for the greater part of its course in the state of Maine. The principal lake in New Hampshire is Lake Winnipiseogee, which is of an irregular shape, about 25 miles in length, and varying from 1 to 10 in breadth. Its depth is great, and the scenery is very picturesque and beautiful. There are also many smaller lakes, of which Umbagog, on the confines of Maine, Connecticut Lake, and Squam Lake, are the chief. The whole surface of the water in this state is estimated to amount to 110,000 acres. The climate of New Hampshire is severe, but less variable than that of Maine and of the other northern states. The winters are long, and the snow lies from November till April, and sometimes till May; while the mountains are covered with snow for the greater part of the year. The spring is generally wet and foggy, but great heat is often experienced in the summer, when the thermometer sometimes stands above 100°. The soil is in general not very fertile; but the labour and industry of the people have succeeded in rendering it productive of many valuable crops. The richest portions are those along the banks of the rivers, especially the Connecticut. The uplands afford good pasture ground; and the whole country, notwithstanding its few natural advantages, has a rich and flourishing appearance. The lower slopes of the mountains are thickly covered with forests of oak, pine, beech, maple, walnut, &c.; while on the lower regions elm, ash, birch, poplar, and other trees abound. The amount of cultivated land in the state in 1850 was 2,251,488 acres; and during the year ending June 1, 1850, the produce was 185,658 bushels wheat; 183,117 rye; 1,573,670 maize; 973,381 oats; 70,856 peas and beans; 65,265 buckwheat; 70,256 barley; 4,304,919 potatoes; 1,108,476 lb. wool; 6,977,056 butter; 3,196,563 cheese; 257,174 hops; 7652 flax; 1,298,863 maple sugar; 117,140 bees' wax and honey; 598,854 tons hay; L.51,781 orchard produce; and L.11,833 market-garden produce. The number of horses in the same year was 34,233; milch cows, 94,277; working oxen, 59,027; other cattle, 114,606; sheep, 384,756; and swine, 63,487; while the total value of live stock in the state was L.1,848,310. The state of New Hampshire is actively engaged in manufactures; for which great conveniences are afforded by the water power which is furnished by the different rivers and streams. There were in 1850, 3301 manufactories in the state, of which 44 were cotton factories, employing 2911 male, and 9211 female hands, having a capital of L.2,280,000, consuming L.1,008,210 of raw material, and producing 113,106,247 yards of cotton and 140,700 lb. of yarn, valued at L.1,839,708; 61 woollen factories, employing 926 male, and 1201 female hands, having a capital of L.507,850, consuming L.264,023 of raw material, and producing 9,712,840 yards of cloth and 165,200 lb. of yarn, valued at L.443,277; 29 iron-foundries, furnaces, &c., employing 390 hands, having a capital of L.49,700, consuming L.39,073 of raw material, and producing 6074 tons of iron, valued at L.80,850; and 163 tanneries, having a capital of L.92,076, consuming L.112,867 of raw material, and producing leather valued at L.187,586. Ship-building is carried on to a considerable extent in New Hampshire; and the number of vessels built in 1852 was 14, with an aggregate tonnage of 9515. The whole of the vessels owned in the state in the same year had a tonnage of 24,891, of which 2283 tons were engaged in the cod and mackerel fishing. The trade of the state is very inconsiderable, as there is only one port of entry in the state, viz., Portsmouth; while there are few rivers capable of affording facilities for inland navigation. The tonnage of the vessels that entered in 1850 was 11,044; of those that

New Hampshire. cleared 8213. The number of vessels built in the state in the year ending June 30, 1856 was 10, and their tonnage 10,395. The total value of exports for the same year was L.1097, and of imports L.5068.

The government of the state is in the hands of a governor, who is appointed annually by the people, and has a salary of L.208. He is assisted by an executive council of 5 members; and there is also a senate of 12, and a house of representatives of 286 members, popularly elected. The judicial establishment consists of a supreme court, composed of a chief justice and four associates, and of a court of common pleas, having one chief justice and two associates. The supreme court has exclusive jurisdiction in criminal cases; and there is a right of appeal to it from the court of common pleas in civil cases where the matter in dispute exceeds L.20 in value. For legal purposes, the state is divided into five districts, in each of which the supreme court holds two annual terms. The amount of the public income for the year ending June 2, 1857, was L.43,636, and the expenditure for the same year was L.40,187. The total value of the taxable property in New Hampshire in 1856 was L.25,239,460; and in June 1857 the total number of banks in the state was 52, their aggregate capital L.1,048,185, and their circulation L.741,302. There were also at that time 20 savings-banks, of which the deposits were L.802,115, and the total means L.843,332. There are numerous railways in the state, crossing it in various directions, and communicating with the principal towns of New England. The total length of all the lines in operation in January 1857 was 480 miles. There are also several canals in New Hampshire; and telegraphs have been established between the principal towns. The number of churches in the state in 1850 was 602, being one for every 528 inhabitants; and of these the Baptists owned 180; the Christians 23; the Congregationalists 172; the Episcopalians 11; the Quakers 15; the Methodists 99; the Presbyterians 13; the Union Church 32; the Unitarians 13; the Universalists 36, &c. The total value of church property was L.291,995. The interests of education in the state are committed to the care of a board of commissioners from the several counties. The number of scholars in 1856 during the winter was 67,103; and in summer 58,203. The number of teachers was 1077 male, and 3042 female. The amount of money raised by taxation for schools was L.44,230; and the whole amount expended for district schools during the year 1856 was L.53,908. There were, in the same year, 89 academies and private schools in the state; and also a college at Hanover, with 16 professors, 251 students, and a library of 31,900 volumes; three theological schools belonging to Methodists, Congregationalists, and Baptists, having in all 99 students; and one medical school, having 5 professors, and 50 students. The principal charitable institution of the state is the lunatic asylum at Concord, which was opened in 1843, and has at present 170 inmates. It is supported by the public funds; and the receipts in 1857 amounted to L.5638, and the expenditure to L.5502. There is also a house of reformation for female and juvenile offenders, and a state prison at Concord. The earliest settlements in this part of the country were made by Mason and Gorges, who obtained in 1622, from James I., a grant of the land between the Merrimack and the Kennebec; and, in the following year, colonies were planted at Portsmouth and Dover. In 1641, the colonists placed themselves under the protection of Massachusetts, of which colony they continued to form a part until 1679, when their country became a royal province. It was, however, afterwards united with Massachusetts; and was finally, in 1749, made an independent colony. New Hampshire suffered very much at one period from the inroads of the Indians; but having escaped this danger, the colony rapidly increased in wealth and population.

Although this state took an active part in the war of the American revolution, no important battles were fought within its territory, either at that time, or during the war of 1812. The capital of the state is Concord. Pop. (1850) 317,976.

NEW HAVEN, a town of the United States of North America, state of Connecticut, pleasantly situated on a plain at the head of New Haven Bay, an inlet of Long Island Sound, 76 miles N.E. of New York, and 160 S.W. of Boston. The plain on which it stands slopes gradually to the sea, and is bounded on the other three sides by hills, which on the E. and W. form steep and rugged precipices, from 300 to 400 feet high. Three small rivers traverse the plain from N. to S.; the Quinepiack on the E., the Mill River which joins the former near its mouth, and the West River; and these rivers are crossed by several bridges. The town is regularly laid out, and very handsomely built; the streets are broad, and in general lined with rows of fine elms; and in the centre there is a public park, surrounded and intersected by numerous avenues of elms. On account of this conspicuous feature, New Haven has been called the "City of Elms." There are also several other squares; and the public burial-ground is beautifully adorned with trees, shrubs, and flowers. The state house is a handsome building of brick, covered with stucco, in the Grecian style, and contains halls for the legislature and courts of law. There are about 22 churches, many of which are remarkable for neatness and elegance. Of these 8 are Congregational, 4 Episcopal, 4 Methodist, 2 Baptist, 2 Roman Catholic, 1 Universalist, and 1 Jewish synagogue. There is also a handsome state hospital, built of stone, and placed on a rising ground. Yale College, which is next to Harvard, the principal university in the United States, was founded in 1700, and transferred to New Haven in 1717. It has extensive buildings, partly of brick and partly of stone; and that which contains the library is a handsome Gothic structure. It has 24 professors, 365 students, and a library of 63,500 volumes. There are at present five departments in this college—those of arts, divinity, medicine, law, and science. Yale College has a valuable museum of mineralogy and geology, which is the finest of the sort in the United States, and surpassed by few in the world. New Haven has also numerous schools which enjoy a high reputation, and several literary and scientific societies. It is connected by railway with the principal places in the surrounding country; and steamers ply daily between this and New York. The railway station for all the lines that lead to the town is a handsome building of brick with towers. The harbour is large and safe, but the shallowness of the water prevents the entrance of large vessels; and, though a long quay has been built into the centre, the continual accumulation of sand at the bottom has neutralized all the benefit that might have been derived from this erection. The trade of the port is chiefly with the West Indies, and mules form one of the principal articles of export. The number of vessels that entered from foreign parts in the year ending June 30, 1852, was 110, and the tonnage 21,356; those that cleared were 108, and the tonnage 20,580. The manufactures of the town are considerable; and the principal articles produced are carriages, clocks, India-rubber goods, boots, shoes, and hardware. Pop. (1850) 22,529; (1853) about 23,000.

NEWHAVEN, a village of Scotland, county of Mid-Lothian, on the shore of the Firth of Forth, 2 miles N. of Edinburgh. It consists for the most part of poor houses, inhabited by a fishing population; but there have been recently erected many handsome houses and villas, which are chiefly used as seaside residences. There are here an Established and a Free church; and a stone pier, which is convenient for small fishing-boats. Pop. 2103.

Sussex, near the mouth of the Ouse, 8 miles E.S.E. of Brighton. It has a parish church, a dissenting church, and a national school. The harbour has recently been much improved, and it is now considered the best between the Downs and the Isle of Wight. Steam-packets sail regularly from this to Dieppe, performing the passage in four or five hours. Pop. (1851) 1260.

NEW IRELAND, an island in the South Pacific Ocean, between S. Lat. 2. 40. and 4. 52.; E. Long. 150. 30. and 152. 50. It is separated from New Britain on the S.W. by St George's Channel, and from New Hanover on the N.W. by Byron's Straits. It is about 200 miles long by 12 in average breadth; and the coasts are indented by several small harbours. The surface is hilly, the elevations attaining a height of 1500 or 2000 feet; but they are all covered with forests of bread-fruit, cocoa, and other trees. The lower parts are well cultivated, and produce the sugar-cane, the banana, yams, &c. Dogs, pigs, and turtles, are the chief animals. The inhabitants, like those of the neighbouring island of New Britain, belong to the race of Australian negroes. For a description of them see AUSTRALASIA. Fancy woods and tortoise-shell seem to be the only articles of commercial value to be obtained in this island.

NEW JERSEY, one of the United States of North America, lying between N. Lat. 38. 55. and 41. 21., and W. Long. 73. 58. and 75. 29.; and bounded on the N. by New York; E. by the Hudson River and Staten Sound, which separate it from New York, and by the Atlantic; S.E. by the Atlantic; S.W. by Delaware Bay; and W. by the River Delaware, which separates it from the states of Delaware and Pennsylvania. Its length from N. to S. is about 168 miles; its breadth varies from 37 to 70 miles; and its area is 8320 square miles. The northern part of the state is hilly, being crossed from S.W. to N.E. by several branches of the Alleghany ridge. Of these the principal are,—the Blue Mountains in the extreme N.W., Schooley's Mountain, the Trowbridge range, and First Mountain, further to the S.E. These hills, though not remarkable for their height, present in general a bold and picturesque appearance, and inclose beautiful and fertile valleys, containing some of the best land in the state. The west bank of the Hudson is skirted for the length of 20 miles by a ridge of rocks called the Palisades or Cloister Hill, which in some places rises steeply above the river to the height of 200 feet. The middle part of the state is the most agricultural portion, and has a rich and beautiful appearance. That part of New Jersey which lies S. of Trenton and Raritan Bay consists of a flat sandy plain, never rising above 60 feet from the sea level, except to the S.E. of Raritan Bay, where the Nevisink Hills rise to the height of 300 or 400 feet, and present a conspicuous object to the navigator as he leaves the harbour of New York. From the low sandy promontory called Sandy Hook, opposite to the entrance of New York Harbour, to Cape May, which forms the eastern boundary of Delaware Bay, the whole coast consists of a low sandy shore, having in some places, inlets and long, narrow, and shallow lagoons. The heavy surf of the Atlantic is constantly beating against this beach, and the form of the coast-line is being constantly changed. The principal inlets on this coast are Barnegat Bay, Little Egg Harbour, Great Bay, and Great Egg Harbour. Further inland there is a tract of salt marsh, which gradually gives place to the sandy plain of the interior. The shores of Delaware Bay are skirted by a similar salt marsh; but along the left bank of the River Delaware the land is more elevated, and a branch of the mountains of Pennsylvania crosses the river at Trenton, and forms, by a ledge of rock over which the waters roll, the Falls of Trenton.

The rivers of New Jersey, with the exception of the Hudson and Delaware, which merely bound the state, are not of great size. The Hackensack from the north, and

the Passaic, which follows a circuitous course from the west, fall into Newark Bay; the former being navigable for small vessels to the distance of 15 miles, and the latter to that of 10 miles from the sea. The Passaic is remarkable for its falls near the village of Paterson, which are situated in the midst of wild and beautiful scenery; but the volume of water has been much diminished by being carried off for mills, and it is only in times of flood that the full magnificence of the cataract can be seen. The Raritan, from the west of the state, falls into the bay of the same name, and is navigable for 17 miles; the Great and Little Egg Harbour rivers fall into the Atlantic, and the Maurice falls into Delaware Bay, each being navigable for about 20 miles; and there are also numerous rivers, but none navigable, which discharge themselves into the Delaware. The hills in the north of the state consist for the most part of sandstone towards the west, and of gneiss towards the east; while in the valleys of this region are found strata of slate, sandstone, and limestone. The central and southern regions belong to the chalk formation, and contain beds of marl, which are of great value for manure. Besides these, the mineral riches of New Jersey consist of iron, which occurs in great abundance in various forms; copper, containing in some places silver ore; zinc, of which the mines in this state are among the richest in the Union; slate, marble, limestone, and granite. The soil of the country varies considerably in different parts; the central and southern regions, though not naturally rich in soil, may be easily made to produce excellent crops of wheat, maize, and potatoes; while the northern portions, though not very fertile, are well adapted both for agriculture and pasturage. The coldness of the climate is moderated in the south by the neighbourhood of the ocean; while in the north it resembles that of the south of the state of New York and the north of Pennsylvania. The mean temperature at Lambertville of the warmest month (July) for the year ending 30th June 1852 was 82°·43; that of the coldest month (January), 30°·74. The greatest heat in the same year was 97°, the greatest cold 16°·5, and the mean temperature of the year 57°·82. The central and southern parts of the state contain extensive forests of pine, much of which is used for charcoal, and sold at Philadelphia. There are also cedar swamps in the south of New Jersey; and the principal other trees that occur here are oak, hickory, sycamore, dogwood, &c. The quantity of cultivated land in the state in 1850 was 1,767,991 acres; and the produce in that year comprised 1,601,190 bushels of wheat, 1,255,578 of rye, 8,759,704 of maize, 3,378,063 of oats, 14,174 of peas and beans, 3,715,261 of potatoes, 874,934 of buckwheat, 91,331 of grass seeds, 375,396 lb. of wool, 9,487,210 of butter, 565,756 of cheese, 182,965 of flax, 186,694 of bees' wax, 453,950 tons of hay, L.126,511 worth of orchard produce, and L.99,006 worth of market produce. The number of horses in New Jersey in the same year was 63,955; of milch cows, 118,736; of working oxen, 12,070; of other cattle, 80,455; of asses and mules, 4089; of sheep, 160,488; of swine, 250,370; and the total value of the live stock was L.2,224,848. The state of New Jersey is, considering its population, extensively engaged in manufacturing industry. In 1850 there were 4374 manufactories, each annually producing goods to the value of L.100 and upwards. Of these, 21 were cotton factories, employing 616 male and 1096 female hands, having a capital of L.309,060, consuming L.138,880 worth of raw material, and producing 8,122,580 yards of cloth, and 2,000,000 lb. of yarn, valued at L.301,148; 41 woollen factories, employing 411 male, and 487 female hands, having a capital of L.102,970, consuming L.114,296 worth of raw material, and producing 771,100 yards of cloth, and 350,000 lb. of yarn, valued at L.242,590; 108 furnaces, forges, &c., employing 1996 hands, having a capital of L.536,891, consuming L.198,894

New Jer-
sey.

New
Jersey.

worth of raw material, and producing 42,452 tons of cast and wrought iron, valued at L.390,881; 133 tanneries, with a capital of L.119,342, consuming L.88,237 worth of raw material, and producing leather valued at L.150,928; besides numerous breweries and distilleries, producing 34,750 barrels of ale, and 1,250,530 gallons of whisky and wine. The state of New Jersey, as it lies directly between the two largest cities of the United States, New York, and Philadelphia, is traversed by several lines of railway, which have in general for their object the connection of New York with Pennsylvania. In January 1857 the length of the railways in the state was 492 miles. There are also several canals, the total length of which amounts to 145 miles. The foreign trade of New Jersey is not very great; for, though it is bordered on one side by the sea, and on two sides by navigable rivers, and though there are several seaports within its limits, the neighbouring great cities and harbours of New York and Philadelphia carry off most of the direct commerce to these places. The exports for the year ending June 30, 1856, amounted to L.80, and the imports for the same year were L.576. There is, however, an important internal and transit trade carried on through this state. The number of ships built in the state in the same year was 75, and their tonnage 9543. There were, in January 1857, 46 banks, with an aggregate capital of L.1,371,406, and a circulation of L.991,533.

Government.

The executive power in the state is in the hands of a governor, who is elected by the people for three years, and has a salary of L.374 and fees. The legislature consists of a senate, elected for three years, composed of one member from each county; and a house of representatives, composed of sixty members, annually elected. The judiciary consists of a supreme court, composed of a chief and six associate justices, who are appointed for a period of seven years by the governor, with the consent of the senate. There are also a court of errors and appeals, consisting of a chancellor, the judges of the supreme court; and six others, appointed in the same way for six years; a court of chancery, over which the chancellor presides; circuit-courts, and courts of oyer and terminer, held thrice a year in each county by the judges of the supreme court; and courts of common pleas. New Jersey sends five members to the House of Representatives of the United States. The public revenue for 1856 was L.37,804, and the expenditure for the same year L.37,506.

Religion,
education,
&c.

The number of churches in the state in 1850 was 807, of which 107 belonged to Baptists, 66 to the Dutch Reformed Church, 51 to the Episcopalians, 52 to the Quakers, 312 to the Methodists, 146 to the Presbyterians, and 21 to the Roman Catholics. The proportion of churches to the whole population is 1 to every 606 inhabitants. The whole value of church property in the same year was L.737,588. The educational establishments of the state consist of 3 colleges, having in all 72 professors, 460 students, and 33,000 volumes in their libraries; theological seminaries of the Presbyterian and Dutch Reformed Churches; besides numerous lower schools, at which, in 1856, 125,035 out of 176,350 children between 3 and 18 were educated. The whole number of teachers in the same year was 1942; and the total amount of funds raised for purposes of education was L.107,132. The principal benevolent institution of New Jersey is the state lunatic asylum, at Trenton, containing 233 patients in 1856. There is also, at the same place, a state prison.

History.

The earliest settlements in this country were made by the Dutch, not long after their arrival in New York, between 1614 and 1624. These were planted in the east of the district, between the Hudson and Delaware; the whole of which was claimed by the Dutch, although the Swedes had made some settlement in the western part of the same country. These claims were, however, disregarded by the

British; for, in 1664, Charles II. granted to the Duke of Newmarket the whole of this country, and in the same year the duke sold it to Lord Berkeley and Sir George Carteret, in honour of the latter of whom, a native of Jersey, it received the name which it still bears. The Dutch again got possession of it in 1673, but resigned it on the conclusion of peace in the following year. New Jersey escaped the inroads of the savage tribes which desolated and afflicted most of the older colonies; but, in the war of the Revolution, it was the scene of several victories gained by the Americans, in most of which Washington was present. Among these were the battle of Princeton in 1776, and that of Monmouth in 1778. The state is divided into 20 counties; and had in 1850 a population of 489,555.

Newmarket
||
New
Orleans.

NEWMARKET, a market-town of England, partly in the county of Cambridge, and partly in that of Suffolk, is pleasantly situated at the foot, and on the gently sloping side of a valley, 13 miles E. by N. of Cambridge, and 61 N. by E. of London. There is one principal street, about three quarters of a mile long, only partially paved, but lined with good houses, most of them modern, and many very handsome. It has a market-house, two parish churches, one of which is a fine building, Independent and Methodist churches, a national and other schools, and a savings-bank. Malt and beer are the chief manufactures. The principal importance of Newmarket, however, is derived from horse-racing, for which it is the most famous place in the country. The race-course is about 3 miles to the west of the town, and is between 4 and 5 miles in length. There is also a training ground on the slope of a hill to the south of Newmarket, and the town contains no less than fifteen training establishments for horses. Races seem to have been established here as early as the end of the sixteenth century; and soon afterwards, in the reign of James I., they became a fashionable amusement. A house was erected at Newmarket for the accommodation of that monarch, which was destroyed during the civil war, and restored in the time of Charles II. Part of it still remains, but the rest has been pulled down. Seven races are held during the year, which attract a large number of visitors. Pop. (1851) 3356.

NEW ORKNEY, a group of islands in the South Atlantic Ocean, lying between 60. and 61. S. Lat., about 675 miles S.E. of Cape Horn. The principal island is called Mainland or Pomona, and another, called Saddle Island, has a lofty mountain, known by the name of Noble's Peak, which is visible from a distance of nearly 70 miles. The islands are all covered with high and rugged hills; and there are found here large numbers of seals, and immense flocks of sea-fowl. This group forms a part of New South Shetland.

NEW ORLEANS, the commercial metropolis of Louisiana, and of the south-western states of the American Union, is situated on the left bank of the Mississippi River, at a distance, by the windings of the river, of about 100 miles from its mouth; Lat. 29. 58. N., Long. 90. 7. W. The position being one of commanding commercial importance, when viewed in connection with the immense area of navigable waters (the shore lines of which, including both banks, being estimated to be 35,000 miles in length) which find their outlet in this direction, the city has progressed in despite of many natural disadvantages. The country in its immediate vicinity has been reclaimed by the industry of man, and there is little or no land on the banks of the river within the state of Louisiana, with an inconsiderable exception at Baton Rouge, which would not be covered by the waters of the Mississippi during a considerable portion of the year, were it not for the artificial embankment which, at vast labour and expense, has been erected. This embankment or levee is 15 feet above low-water mark at New Orleans, or 6 feet above the level of the city, towards which it slopes almost imperceptibly, form-

New Orleans. ing a crescent-shaped quay, several miles in length, which has scarcely a parallel in any part of the world for the advantages it affords for the landing and shipment of produce. Along this line for 6 or 7 miles, during the season of active business, may be seen dense forests of masts of vessels of every nation moored three or four deep.

Public buildings, &c. The city was originally laid out regularly in the form of a parallelogram, with a front of about half a mile on the river; but in its subsequent progress the same regularity has not been observed. In the modern portions, however, including the chief business parts, and what, until very lately, was known as Lafayette, the streets are generally wide, and the buildings large and commodious, displaying much taste and elegance. Within a few years numerous blocks of buildings for stores, four to six storeys in height, have been erected; and private residences, in the upper portions of the city and in the suburbs, are every day advancing in number and style. Airy verandahs, large and beautiful gardens, groves of ornamental trees, among which the orange and the lemon scatter their fragrance and exhibit their mellowed fruit, and the magnolia spreads its luxuriant shades, adorn and beautify the town. There are many spacious public squares, laid out with taste, and shaded with beautiful trees. In one of these, originally known as the Place D'Armes, but now changed to Jackson Square, shrubbery and flowers abound; vases, statuettes, and busts crown the walks; and, in the centre, a bronze equestrian statue of the hero of New Orleans, the work of an American artist, rises to great height. Among the public buildings, the New Custom-House is most notable. It has been in course of construction about ten years, and will not be completed for two or three years more. It will cover an area greater than that of any public building in America, except perhaps the Federal Capitol, and will cost several millions of dollars. Among the finest buildings in the city are the Municipal Hall, Odd Fellows' Hall, Merchant Exchange, United States' Branch Mint, Charity Hospital, Mechanics' Institute, New School of Medicine, University Buildings, New Marine Hospital, and Widows' Home; the St Charles and St Louis Hotels, City Hotel, banks, and Arcade; and among the churches, the Cathedral, St Patrick's, the Presbyterian church in Lafayette Square, the Episcopal in Canal Street, and the Independent in Camp Street. The numerous cotton-presses and markets are also on the largest scale, possessing no inconsiderable interest. The St Charles' Hotel is one of the most imposing structures in America, and has been lately rebuilt upon the site of a similar building destroyed by fire. It is capable of accommodating 800 to 1000 guests, and is said to have been built at an expense of about L.100,000. The public cemeteries are embellished and adorned in a style peculiar to the city.

Education, religion, &c. The educational statistics of New Orleans show a larger proportion of children at the public schools than either Cincinnati, Baltimore, or New York. The system has been some years in operation, and is highly honourable to the city. Upwards of L.40,000 are annually expended upon the public schools, and about 10,000 children are taught. The private schools are not so numerous as in other cities, and the means of acquiring an academical education are much circumscribed. A university has been located at New Orleans, with law, medical, and collegiate departments. The medical college has been in existence since 1835, and has matriculated over 2000 students, the number being, in 1856, 200. The law school was organized in 1847, and has an average of forty to fifty students. In the collegiate department little has yet been accomplished, there being no sufficient organization or endowment. A chair of commerce, founded by a merchant of New Orleans (Maunsel White), is a somewhat novel feature introduced into this university. The subject of this university is again before the legislature of the state, and it is thought that efficient

New Orleans. improvement will be the result. A new medical school, established during the last year, affords much promise of excellence, and numbers many students. The medical student has free and constant access to all the hospitals. Of these the Charity Hospital is the chief, and is the largest institution of the kind in America, and perhaps the most efficiently regulated. It is an immense building, admirably arranged and ventilated, with handsome grounds, and accommodation for 1000 patients at one time. Among the other hospitals are the Naval, on the opposite bank of the river, Stone's, the Franklin Infirmary, and a new military hospital in course of construction.

There are at New Orleans an academy of sciences, which meets regularly for discussion and reports; a lyceum connected with the public schools, where lectures and addresses from distinguished men are frequently delivered; and, connected with these schools, a library of 10,000 volumes, well selected, in all departments of literature and science. A free public library attached to the Mechanics' Institute was lately destroyed by fire. Newspapers are published in the French, Spanish, and German languages, as well as in English. Two monthly medical journals, of established reputation, are published; and De Bow's *Monthly Review*, a periodical devoted to the exposition of the industry of the southern and western states.

By the census of 1850 (but there have been many changes for the better since that time), it appeared there were 13 Roman Catholic, 1 Episcopal, 2 German Reformed, 1 Jewish, 5 Methodist, 4 Presbyterian, 1 Universalist, 1 Christian, and 2 other churches, with accommodation for 27,350 persons, or 23 per cent. of the population (Boston being capable of accommodating 56 per cent., and Charleston 67 per cent.). Total value of church property L.323,703, which is now swelled to about L.400,000.

In proportion to population and wealth, there is no city in America which produces so few manufactures as New Orleans. With the exception of a few foundries and machine shops, no efforts in establishing factories on a large scale have been successful. This is owing to the cost of labour, the climate, and (as much as to either) a deficiency of capital. In 1850 the capital invested in manufactures was reported at L.618,675; hands employed, 3134; product, L.931,422. Nine schooners and ten steamers were built in Louisiana in 1856, of which nearly all were at New Orleans.

It is the commerce of New Orleans which gives to the city its distinctive character, and extends its reputation throughout the world. This commerce has been gradually extending from the humblest beginnings; and so admirable is its position in this respect that, vast as is the present trade, it must continue to grow with the development and settlement of the great interior basin of which it is the mart. Railroads and canals may divert, as they are now diverting, large portions of her trade to the markets of the eastern states; but there will be left sufficient at all times to follow the *natural* channels, and add to the commercial opulence of New Orleans. Already is the city active in giving aid to such internal improvement schemes as will counteract the strokes of her enterprising rivals; and, in a few years she has appropriated many millions of dollars for this purpose.

At the time of the transfer of New Orleans to the Americans in 1803, its commerce was very inconsiderable. In 1817, 137,746 tons entered or cleared from New Orleans; and there also arrived in the year 1500 flat-bottomed boats and 500 barges. The exports were L.2,812,713; while in 1856 they amounted to L.30,053,346. The imports through the custom-house, for the fiscal year ending 30th June 1856, amounted in value to L.3,579,856. In the year ending 31st June 1856, the foreign exports of New Orleans reached L.16,786,798; being larger than those of any American port except New York, and being about

Newport. one-fourth of the whole exports of the Union. Excluding coin and bullion, New Orleans exports more largely of domestic goods than New York. The amount of cotton received at New Orleans, in the year 1855-6, amounted to 1,759,293 bales, or one-half of the whole crops of the United States, and was valued at L.14,660,772. In 1856 the total tonnage which entered and cleared at New Orleans was 1,436,299. The total arrivals,—ships, 874; barks, 375; brigs, 261; schooners, 399; steamers, 234; total, 2143: besides steam-boats, 2956. In 1854 there were 5 banks in New Orleans, with a capital of L.3,306,348; 3 free banks, with a capital of L.560,157; and 2 other banks in liquidation. In 1856 the banking capital of New Orleans had not increased, and is believed to be inadequate to the wants of its commerce. Under the general banking law lately adopted it is believed there will be an amelioration.

History
and popu-
lation.

New Orleans was founded in 1717 by Bienville, the governor of the province of Louisiana under the French. In 1769 the colony was transferred to Spain. Its population in 1785 reached 4780. Napoleon I. obtained it from Spain, and sold it to America in 1803, after it had been for many years the centre of intrigues and negotiations. On January 8, 1815, was fought the battle of New Orleans, a few miles below the city, between General Jackson, at the head of the American forces, and the British under General Pakenham, ending in the defeat of the latter with a loss in killed and wounded of nearly 3000 men. The American loss was but 13. The laws, manners, and institutions, of the French and Spanish inhabitants of New Orleans are blended happily with those of the American, and all distinctions and prejudices are being gradually obliterated. The population in 1788 reached 5331; in 1797, 8056; in 1810, 17,240; in 1820, 27,176; in 1830, 46,310; in 1840, 102,193; in 1850, 116,375; in 1856, about 125,000. Of the total population of 1850, 59,312 were white males, and 44,431 white females; 4104 free coloured males, and 6196 free coloured females; and 8012 male, and 11,595 female slaves. Of the same population (excluding slaves) 50,470 were born in foreign countries, and only 48,601 were born in the United States.

(J. D. B. D^o B.)

NEWPORT, a municipal and parliamentary borough and market-town of England, county of Hants, in the Isle of Wight, on the left bank of the Medina, 18 miles S.E. of Southampton, and 82 S.S.W. of London. It is a neat well kept town, with good houses, chiefly built of brick, and has five principal streets, extending from E. to W., and several others crossing them at right angles. The parish church is a large and plain building, built in 1172, but frequently since then repaired and altered, though now in a somewhat dilapidated condition. In it was found in 1793 the coffin of the Princess Elizabeth, daughter of Charles I., who died at Carisbrook Castle, shortly after her father's execution. Newport has besides a modern Episcopal church, with an embattled tower; and Baptist, Independent, Wesleyan, Unitarian, Roman Catholic, and other churches. There are a handsome town-hall and market-house; a theatre; jail; grammar-school, founded in 1619, and remarkable as the scene of a conference between Charles I. and the Parliamentary Commissioners; several other schools; a public library, occupying one of the best buildings of the town; almshouses; and an infirmary. The industry of the town is chiefly employed in the making of lace, in which about 300 hands are engaged, and in the manufacture of implements of agriculture. For the latter of these Newport is widely famed. The market of Newport, which is held on Saturday, attracts a large number of persons from all parts of the Isle of Wight; and the corn and other produce of the island are exported from this town; while coal, provisions, and manufactured goods are imported. The River Medina, here crossed by a bridge, is navigable for small vessels as far as the town, which the tide nearly reaches. There

is a quay in front of the town for the accommodation of ships. In the neighbourhood of Newport there are some beautiful walks; and a fine view of the surrounding country may be obtained from a hill, called Mountjoy, to the S. of the town. The borough returns two members to the House of Commons. Pop. parliamentary borough (1851), 8047.

NEWPORT, a municipal and parliamentary borough and market-town of England, in the county of Monmouth, is situated on the right bank of the River Usk, which is here crossed by a fine stone bridge about 5 miles above its mouth, and 20 miles S.W. of Monmouth. The older parts are irregularly built, but other parts of it are of modern construction and of elegant appearance, and there are a number of handsome buildings. The parish church of St Woollos is an edifice in the Norman style, of which the nave and western archway are still well preserved in their original form; while the aisles are not older than the middle of the fifteenth century. Newport has two other Episcopal, besides Wesleyan and Calvinistic Methodist, Independent, Roman Catholic, and Baptist churches; several schools; an atheneum; a mechanics' institute; a working-man's institute; a dispensary; and a savings-bank. The town-hall and the post-office are handsome buildings, which have been recently erected. Ship-building is carried on to a great extent here; and there are also several iron foundries, a large nail-work, manufactories of anchors, chain-cables, &c. Newport has a spacious dock, which is able at all times to admit vessels of any size. The number of vessels registered as belonging to the port in 1856 was 92, and their tonnage 16,280. During the year 1856 there entered the port:—In the coasting trade, 1544 sailing vessels, tonnage 86,246; and 468 steamers, tonnage 34,298: in the colonial trade, 70 sailing vessels, tonnage 17,040; and 1 steamer, tonnage 602: in the foreign trade, 461 sailing vessels, tonnage 96,334; and 2 steamers, tonnage 1200—in all, 2075 sailing vessels, tonnage 199,620; and 471 steamers, tonnage 36,000. In the same year there cleared:—In the coasting trade, 6777 sailing vessels, tonnage 414,002; and 269 steamers, tonnage 17,259: in the colonial trade, 151 sailing vessels, tonnage 39,019: in the foreign trade, 898 sailing vessels, tonnage 183,440; and 5 steamers, tonnage 2828—in all, 7826 sailing vessels, tonnage 636,461; and 274 steamers, tonnage 20,087. Thus the total number of vessels entered in that year was 2546, tonnage 135,620; of those that cleared the number was 8100, and the tonnage 656,548. The town is connected with Gloucester, Cardiff, and Pontypool by railway, and with the last of these places also by the Monmouthshire Canal, which facilitates the intercourse with the neighbouring country. The trade of Newport is very extensive; the chief exports being coal, iron, and tin; while timber, provisions, and other articles are imported from America. The principal market-day is Saturday, and there are several annual fairs. Of the Castle of Newport, which is supposed to have been built by the Earl of Gloucester, a son of Henry I., only a square tower and a part of the great hall now remain, and are at present employed as a brewery. Newport was attacked in 1839 by a body of Chartists under John Frost; but the ringleaders were afterwards convicted of treason, though the punishment was commuted to transportation. The borough unites with Monmouth in sending a member to Parliament. Pop. parliamentary borough (1851), 19,842.

NEWPORT, a municipal borough and market-town of England, county of Salop, on the borders of Staffordshire, 16 miles E.N.E. of Shrewsbury, and 142 N.W. of London. It is a small town, and has a parish church, part of which is of the fifteenth century, and which would be very beautiful in the interior were it not for the brick side aisles which have been added in more recent times. There are also Roman Catholic and Independent churches, two free schools, two sets of almshouses, and a savings-bank. The

Newport only manufacture carried on here is that of stockings. Pop. (1851) 2906.

Newport-Pagnell.

NEWPORT, or *Newport-Tip*, a market-town of Ireland in the county of Tipperary, 11 miles N.N.E. of Limerick; has a parish church, a Roman Catholic church, a national school, and infantry barracks. Pop. (1851) 1114.

NEWPORT, a seaport of the United States of North America, in the state of Rhode Island, is beautifully situated on the slope of a hill on the W. side of the island, 28 miles S. by E. of Providence. It is well built; and has recently been considerably improved in this respect. The principal buildings are—the state house, a brick edifice, having an octagonal cupola, and containing accommodation for the state legislature and courts of law; a library and atheneum; a custom-house; a market-house; a masonic hall; an armoury; 15 churches of various denominations; and numerous fine hotels. Previously to the American Revolution, Newport was of great importance as a commercial city, and rivalled in that respect those of New York and Boston; but it suffered greatly during the war that followed that event; and, at its close, the population was reduced from 10,000 to 5500. The vessels belonging to the port in 1852 had an aggregate tonnage of 11,000 enrolled and licensed; of which 1851 tons were employed in the whale fishery, 3785 in the coasting trade, 560 in cod and mackerel fishing, and 255 in steam navigation. The vessels that entered in that year were 28, and their tonnage 4863; those that cleared were 20, and their tonnage 4337. The town has 7 banks, with an aggregate capital of L.130,000, and a savings-institution, whose deposits amount to L.60,791. There are also several woollen and cotton factories, and 5 newspaper offices, in the town. The assessed value of taxable property is about L.1,000,000. Newport, on account of its beautiful situation and mild climate, is a favourite summer resort, especially for visitors from the south. There is here a curious ancient structure of unknown origin, and equally mysterious in the purpose for which it was designed. It is a round building, 28½ feet high, and 23½ in diameter; and, in its lower part, it has 8 pillars about 10 feet in height. The walls are about 18 inches thick, and are pierced by 3 small loopholes. There is also a fireplace and chimney; but the roof and floors have disappeared. Some have supposed this to be a religious edifice, built by the Northmen; and others that the original settlers used it as a place of defence against the Indians: but these are mere conjectures, and no certain knowledge can be obtained about its origin or use. Pop. (1850) 9563; (1853) about 10,000.

NEWPORT, a seaport of Wales, in the county of Pembroke, on the slope of a hill near the mouth of the Nevern, 7 miles E.N.E. of Fishguard. The streets are mean and irregular; and the whole place has a very decayed appearance. In the neighbourhood there are some Druidical remains; and the town has the ruins of an old castle, built by the Normans in the thirteenth century, but afterwards destroyed by Llewelyn. Newport has an old parish church, and others belonging to Baptists, Independents, and Methodists, as well as several schools. Limekilns, malt-houses, carding and flour mills are in operation; and, by means of the harbour, which is secure, the export of slates, and the import of coal, timber, &c., is carried on. Pop. (1851) 1716.

NEWPORT-PAGNELL, a market-town of England, county of Buckingham, is situated near the confluence of the Ouse and Ousel, 48 miles N.N.W. of London. The latter river divides the town into two parts, and is crossed by an iron bridge, built in 1810. The parish church is a large ancient building, with a square tower and pinnacles. There are also Baptist, Independent, and Methodist churches; several schools; almshouses; a circulating library; and a savings-bank. The only manufacture here is that of lace, and even that is not so largely carried on as formerly; but there is some trade in corn, coal, and timber. Pop. (1851) 3312.

NEWRY, a parliamentary burgh and seaport of Ireland, on the borders of the counties of Down and Armagh, is beautifully situated in the valley traversed by the river of the same name, not far from its mouth in Carlingford Bay, 32 miles S.S.W. of Belfast, and 63 N. of Dublin. It consists of a fine square, and several good and well-paved streets lined with well-built and handsome houses chiefly of brick. The parish church is a fine modern building of early English architecture, with a tower and spire 190 feet high. There are also Presbyterian, Independent, Methodist, and Roman Catholic churches; a town-hall, court-house, two jails, custom-house, infantry barracks, assembly-room, fever hospital, dispensary, and workhouse. The manufactures are extensive, consisting of beer, brandy, leather, linen, cordage, cotton, glass, iron, brass, coaches, &c. The trade of the place is also considerable, especially in the export of butter, eggs, provisions, and cattle, and the import of coals, iron, &c. The river, which is here crossed by four stone bridges, admits vessels of 600 tons burden up to the town, and those of 1000 tons to within 6 miles of it. There is also a ship-canal leading to the sea, and a boat-canal to Lough Neagh, which is 32 miles distant. The number of ships registered at the port, 31st December 1856, was 114, and their tonnage 6648. In that year there entered the port coastwise, 793 sailing vessels, tonnage 47,495; and 254 steamers, tonnage 42,115. From the colonies, 16 sailing vessels, tonnage 7306; from foreign parts, 15 sailing vessels, tonnage 2535—in all, 824 sailing vessels, tonnage 57,336; and 254 steamers, tonnage 42,115. In the same year there cleared, coastwise, 278 sailing vessels, tonnage 15,111; and 250 steamers, tonnage 42,945: for the colonies, 5 sailing vessels, tonnage 2401; for foreign parts, 4 sailing vessels, tonnage 1962—in all, 287 sailing vessels, tonnage 19,474; and 250 steamers, tonnage 42,945. Steamers ply regularly twice a-week between this town and Liverpool, a distance of 153 miles. Newry is a place of great antiquity, and a Cistercian abbey was founded here in 1157 by Maurice M'Loughlin, king of Ireland. The name of the town is supposed to have been derived from the number of yew-trees which grew here, and two especially within the limits of the abbey which was called in Irish *Na yar* ("of the yew-trees"). After the Reformation, the abbey was granted to Sir Nicholas Bagnal, marshal of Ireland, who converted it into a dwelling-house, erected a church and castle, and rebuilt the town. Newry formerly sent two members to the Irish, and now sends one to the imperial Parliament. Pop. 1851) 13,191.

NEW SOUTH SHETLAND, a group of islands in the Antarctic Ocean, lying between S. Lat. 60. 32. and 67. 13., and W. Long. 44. 53. and 68. 15.; about 600 miles S.S.E. of Cape Horn. They are twelve in number, and extend for a distance of 300 miles from N.N.E. to S.S.W., being bounded on the S. by a broad strait called Bransfield Strait, separating them from an extensive country which apparently lies near the S. pole. The islands are rocky and mountainous, having some peaks between 6000 and 7000 feet high. They are covered with snow for nearly the whole year, and the only vegetation that is found in these desolate regions consists of lichens and mosses, and some scanty grass, which appear in a few tracts of the islands in the warmest time of the year. They are of volcanic formation, and some of the mountains are covered with scoræ and lava; while hot springs have been discovered rising from among the snow with a temperature of not less than 146°. The only animals that are found on these islands are sea-fowls, of which the albatross, the penguin, and the sea-cormorant are the principal. Whales and seals of different kinds are found in the seas; and the islands are frequently visited for the purpose of taking these animals. New South Shetland was discovered in 1819 by Captain Smith.

Contrasted
character
of the
newspapers
of the 18th
and 19th
centuries.

IN popular language the term "NEWSPAPERS" has a more restricted application than is given to it in the language of the law. Its use is confined, or almost confined, to such periodical publications as contain more or less of political intelligence, published at short intervals; whilst in the phraseology of the British statutes and law-books the word "Newspaper" is defined to include—(1.) "Any paper containing public news, intelligence, or occurrences, printed in any part of the United Kingdom, to be dispersed and made public;" (2.) Any paper, printed at intervals, not exceeding twenty-six days, of which advertisements are the sole or principal contents; and (3.) "Any paper containing any public news, intelligence, or occurrences, or any remarks or observations thereon, printed in any part of the United Kingdom for sale, and published periodically, or in parts or numbers, at intervals not exceeding twenty-six days between the publication of any two such papers" (provided such paper shall not exceed in dimensions and bulk two sheets of paper, each twenty-one inches in length, by seventeen inches in breadth; and provided also that such paper shall be published for sale for a less sum than sixpence). These definitions and provisos were enacted with reference to duties which have since been repealed, but they have still the force of law, although within smaller limits. And to this cause it is owing that publications, which none of their readers would speak of as "newspapers," still continue to bear that designation in the official returns of the Stamp-Office and the Post-Office.

The elaborate machinery, the wide circulation, and the vast influence of newspapers, are now such familiar things, that it needs some mental effort to conceive of their absence, without an undue depreciation of the public opinion of the days when newspapers were unknown. It is even difficult thoroughly to apprehend the facts that those days are little more than two centuries removed from us, and that the newspaper of a period considerably less distant than one century, was utterly unlike any publication that now bears the name. A few men, indeed, of high principle and vigorous intellect,—of some of whom we shall have to speak hereafter,—earlier employed themselves in political writings, which were periodically issued; but those writers were rather pamphleteers than journalists. The true predecessors of the broad-sheets of our own day were for the most part little better than court newsmen, slenderly endowed even as respects syntax and orthography, who were usually content to retail meagre intelligence in disjointed paragraphs, without a syllable of useful comment or intelligible inference; and of whom not a few were in the habit of filling up occasional blanks by the insertion of false news on one day, and the contradiction of it on another. In this article it will be our aim to indicate, however briefly, the successive steps by which publications of such a class have been transformed into what even statesmen are accustomed to honour with the name of a "fourth estate" of the realm; to show in what manner the legislation affecting newspapers has been gradually amended in Great Britain, though by no means at an equal pace with the improvement of the press itself, and that this amendment of British law is pregnant with instruction for other

countries; and, finally, to sketch, as far as our needful limits will permit, the growth and present statistics of newspapers in the principal countries of continental Europe, as well as in the United States of America.

News-
papers.

I.—THE NEWSPAPERS OF THE UNITED KINGDOM.

The first journalists were the writers of "news-letters." The early Originally the dependents of great men, each employed in keeping his own master or patron well-informed, during his absence from court, of all that transpired, the duty grew at length into a calling. The writer had his periodical subscription-list, and instead of writing a single letter, wrote as many letters as he had customers. Then one, more enterprising than the rest, established an "intelligence-office," with a staff of clerks,¹ and thus realized in sober prose Chaucer's poetical vision of *The House of Fame*:—

"When one had heard a thing, I wiss,
He came straight to another wight,
And 'gan him telling anon, right
The same tale that to him was told.

* * * * *
Whether the tidings were sooth or false,
Yet would he tell it natheless,
And ever more with more increase
Than it was erst: Thus North and South
Went every tiding, from mouth to mouth."

Of the earlier news-letters good examples may be seen in Sir John Fenn's collection of *Paston Letters*, and in Arthur Collins' *Letters and Memorials of State* (better known, perhaps, as the *Sydney Papers*). Of those of later date, specimens will be found in Knowler's *Letters and Dispatches of Strafford*, and in other well-known books. In the recently-published *Diary of Narcissus Luttrell*, examples of manuscript news-letters occur as late as the reign of William III.

By the pains and critical acumen of Mr Thomas Watts, The fiction of the British Museum, the old and obstinate fiction, that "for the first printed newspaper, mankind are indebted to the wisdom of Elizabeth and the prudence of Burleigh," is at length gradually disappearing from current literature, although it has been many times repeated since the first publication of his able pamphlet. The remarkable tenacity of life which characterizes misstatements that have once gained the public ear, may still therefore make it desirable to enumerate the principal reasons which led to the conviction that the *English Mercurie* of 1588 is a forgery. As adduced by Mr Watts himself, they run thus:—(1.) The obvious resemblance of the type to Caslon's "English fount" of the middle of the eighteenth century. (2.) The rigid maintenance of that distinction between u's and v's, i's and j's, which was utterly unknown to the printers of the sixteenth century. (3.) The preservation of the original MSS. from which the printer worked, written in a modern hand, with modern spelling, and with corrections,—obviously those, not of a transcriber, but of an author,—which the printer has copied; these MSS. being on paper manufactured in the early part of the reign of George III.; and (4.) Serious misstatements of fact, and anachronisms of date, of a kind which could not occur in the statements of persons who had taken part in the events they profess to narrate. These

¹ *Cymbal*.—"This is the outer room where my clerks sit,
And keep their sides, the Register in the midst;
The Examiner, he sits private there, within;
And here I have my several rolls and files
Of news by the alphabet, and all put up
Under their heads."—JONSON, *The Staple of News* (acted in 1625).

papers.

The news-
pamphlets
of the 16th
century.

points have been thoroughly established; and it may now be hoped that the *English Mercurie* is finally relegated to its proper niche in the gallery of literary impostures.

Although no genuine newspaper of the sixteenth century can be produced, English pamphlets, as well as French, Italian, and German, occur with such titles as *Newses from Spaine*, and the like. In the early years of the seventeenth they became very numerous. In 1614 we find Butler (the anatomist of Melancholy) pointing a sarcasm against the non-reading habits of "the major part," by adding, "if they read a book at any time . . . 'tis an English Chronicle, St Huon of Bordeaux, Amadis de Gaul, &c., a play-book, or some pamphlet of news."¹ . . . The most eminent purveyors of reading of this sort were Nathaniel Butter, Nicholas Bourne, and Thomas Archer; and by them was issued, in May 1622, the first authentic periodical newspaper which is now known to exist:²—"The 23d of May—*The Weekly News from Italy, Germany, &c.*, London, printed by J. D. for Nicholas Bourne and Thomas Archer." Butter's name does not occur on this number, but on many subsequent numbers it appears in connection sometimes with Bourne's and sometimes with Archer's name; so that there was probably an eventual partnership in the new undertaking. Butter had published *Newses from Spaine* in 1611, and he continued to be a publisher of news until 1641, if not later. It is to him that a passage in the fourth act of Fletcher's *Fair Maid of the Inn* obviously refers:—

... "It shall be the ghost of some lying stationer. A spirit shall look as if butter would not melt in his mouth; a new *Mercurius Gallo-Belgicus*."—*Act iv.*, sc. 2.

In *The Certain Newses of this Present Week* [ending 23d August 1622] the publisher inserted this advertisement:—"If any gentleman or other accustomed to buy the weekly relations of newes be desirous to continue the same, let them know that the writer, or transcriber rather, of this newes hath published two former newes; the one dated the second, the other the thirteenth of August, all which do carry a like title, and have dependance one upon another; which manner of writing and printing he doth purpose to continue weekly, by God's assistance, from the best and most certain intelligence." There are on the face of these early papers many indications that they were published without legal sanction or cognisance. They touched very slightly on home news; and it is probable that for a time the censorship did not much care to interfere with their scraps of foreign intelligence. But as their numbers increased, jealousy appears to have been excited, and forced suppressions to have been imposed. One of the latest which bears Butter's name, entitled *The Continuation of the Forraigne Occurrents for 5 weekes last past*, January 11, 1640 (o.s.), contains this address:—"The Printer to the Reader—Courteous reader, we had thought to have given over printing our foreign aviseoes, for that the licenser (out of a partial affection) would not oftentimes let pass apparent truth, and in other things (oftentimes) so cross and alter, which made us almost weary of printing; but he being vanished, and that office fallen upon another more understanding in these forraigne affaires, and as you will find more candid, we are again, by the favour of His Majesty and the State, resolved to go on printing, if we shall find the world to

give a better acceptation of them than of late, by their weekly buying them." These hopeful anticipations do not appear to have been realized in the individual case of the writer; but a vast number of competitors for public support quickly presented themselves in the stirring times which England was then entering upon, and their productions were eagerly read. November 1641 is especially noticeable for the publication, in the form of a newspaper, of the earliest authentic report of the proceedings of Parliament. *Diurnal Occurrences, or the Heads of several Proceedings in both Houses of Parliament*, was usually, notwithstanding its title, a weekly periodical, and it sometimes contained ordinary news in addition to its staple matter. This was followed, within five years, by a long train of newspapers, most of which were published weekly, such as *The English Post*, *Ireland's True Diurnal*, *England's Memorable Accidents*, *Weekly Intelligence*, *The Kingdom's Weekly Intelligencer*, *The Spy*, *Mercurius Aulicus*, *M. Anglicus*, *M. Civicus*, *M. Rusticus*, *The Weekly Account*, *The Parliament's Scout*, *M. Britannicus*, *The Scotch Intelligencer*, *The Scottish Mercury*, *The Welch Mercury*, *Mercurius Cambro-Britannicus*, *The Kingdom's Weekly Post*, *Le Mercure Anglois* (in French), *The London Post*, *The Country Messenger*, and a multitude more. Nearly the whole of these papers are characterized by clumsiness of arrangement, by extreme paucity of original comment on the news narrated, and very frequently by the fierce virulence of such comments as do appear. The papers of this period which stand out most saliently from the rest are, the *Mercurius Britannicus*, *M. Pragmaticus*, and *M. Politicus* of Marchmont Nedham; and the *Mercurius Aulicus* of John Birkenhead. Nedham was unquestionably both the ablest and the readiest man that had yet tried his hand at a newspaper. He commenced *Britannicus* on the 22d August 1643, zealously advocated in it the cause of the Parliament, and continued its publication until 1647. At that period he changed sides for a time, under circumstances of which we know nothing, save from the reports of his enemies. According to them, "obtaining the favour of a known royalist to introduce him into His Majesty's presence at Hampton Court, ann. 1647, he then and there knelt before him, and desired forgiveness for what he had written against himself and his cause; . . . and soon after wrote *Mercurius Pragmaticus*, which, being very witty, satirical against the Presbyterians, and full of loyalty, made him known to, and admired by, the bravadoes and wits of those times. . . . At length . . . Lenthall and Bradshaw . . . persuaded him to change his style once more [in favour of] the Independents, then carrying all before them. So that, being bought over, he wrote *Mercurius Politicus*, so extreme contrary to the former, that the generality for a long time . . . could not believe that that 'intelligence' could possibly be written by the same hand that wrote the *M. Pragmaticus*. . . . The last [i.e., the *Pragmaticus*] were endeavoured by the parliamenteers to be stifled, but the former, the *Politici*, which came out by authority, and flew every week into all parts of the nation for more than ten years, had very great influence. . . . He was then the Goliath of the Philistines, the great champion of the late usurper, whose pen, in comparison of others, was like a weaver's beam."³ Birkenhead's *M. Aulicus* was also begun in 1643, and con-

¹ So Crabbe, writing in similar strain a hundred and seventy years later:—

"To you all readers turn, and they can look

Pleased on a paper who abhor a book;

Those who ne'er deigned their Bible to peruse,

Would think it hard to be denied their news."—*The Newspaper*, 1785.

² The *Courant*, or *Weekly Newses from Foreign Parts*, of Oct. 9, 1621, mentioned by Nichols (*Literary Anecdotes*, iv. 38), is of doubtful authenticity. It is described as "a half-sheet in the black letter, 4to, out of High Dutch, printed for Nath. Butter." Yet it is probable that future researches will discover papers, serially published, of even earlier date. Publications of this sort have been usually too little cared for in our great libraries.

³ Wood, *Athenæ Oxonienses* (by Bliss), iii. 1182. A new *Mercurius Britannicus* appeared in June 1647, but did not long continue. Another, entitled *M. Britannicus again Alive*, was published in May 1648, and the title was often subsequently revived.

News-
papers.

tinued, although irregularly, until nearly the close of the civil war. According to Wood, Charles I. "appointed him to write the *Mercurii Aulici*, which being very pleasing to the loyal party, His Majesty recommended him to the [University] electors that they would choose him moral philosophy reader;" which was done accordingly. He was assisted in the composition of *Aulicus* by George Digby and by Dr Peter Heylin. He had considerable powers of satire after a coarse fashion, and was one of the few rough-weather royalists who were permitted to bask in the sunshine of the Restoration.

Under Cromwell, the chief papers were *M. Politicus* and *The Public Intelligencer* (of which the first number appeared on the 8th October 1655). These publications were issued on different days of the week, and at length they became conjointly the foundation of our present *London Gazette*. Even at their origin they were in some degree official papers. The *Intelligencer* underwent several modifications of title at various periods, and was for a time edited by Nedham. In 1659 the Council of State caused the following announcement to be published:—"Whereas Marchmont Nedham, the author of the weekly news-books, called *Mercurius Politicus*, and *The Publicque Intelligencer*, is, by order of the Council of State, discharged from writing or publishing any publique intelligence; the reader is desired to take notice that, by order of the said council, Giles Dury and Henry Muddiman are authorized henceforth to write and publish the said intelligence, the one upon the Thursday and the other upon the Monday, which they do intend to set out under the titles of *The Parliamentary Intelligencer*, and of *Mercurius Publicus*." After the Restoration, a monopoly of newspapers was attempted to be set up in favour of Roger L'Estrange, by a royal grant of "all the sole privilege of writing, printing, and publishing all narratives, advertisements, mercuries, intelligencers, diurnals, and other books of public intelligence; . . . with power to search for and seize unlicensed and treasonable, schismatical and scandalous books and papers." L'Estrange continued the papers above mentioned, but changed their titles to *The Intelligencer* and *The News*. In the first number of the former he paints both himself and his epoch in unmistakeable colours:—"Supposing the press in order," he says, "the people in their right wits, and news or no news to be the question, a public Mercury should never have my vote; because I think it makes the public too familiar with the actions and counsels of their superiors, too pragmatistical and censorious, and gives them not only an itch, but a kind of colourable right and license to be meddling with the government." But then, he bethinks him, that in some shape or other the government is sure to be attacked; and therefore ends thus:—"So that, upon the main, I perceive the thing requisite; and (for ought I can see yet) once a week may do the business; for I intend to utter my news by weight, not by measure. . . . The way as to the vent that has been found most beneficial to the master of the book, has been to cry and expose it about the streets, by Mercuries and hawkers, but whether that way may be so advisable in some other respects may be a question." But not even in that day was such a scheme workable. L'Estrange's papers continued only until 1665, and within that short period had their competitors, though of a miserable kind. The first number of *The Oxford Gazette* was published (whilst the court was at Oxford, on account of the great plague then raging in London) on the 14th November 1665, and became *The London Gazette* with the twenty-fourth number, issued on the 5th February 1666. For a very long period it retained its original size of a single leaf in small folio. It contained no news or documents but such as were palatable to the court; and these were retailed in the most meagre fashion, without a *scintilla* of literary ability. After the Revolution, however, it shared, to some

Gazette.

small extent, in the general improvement of the press; and has now been published twice a week, without interruption, and in a continuous and uniform series, for nearly two centuries.

News-
papers.

The excitement which attended the "Popish plot," and the "Exclusion Bill," largely increased the number of newspapers, without much elevating their character. The increase led to a new "Proclamation for suppressing the printing and publishing unlicensed news-books and pamphlets of news" (May 12, 1680), in which it is set forth that, "of late, many evil-disposed persons have made it a common practice to print and publish pamphlets of news, without license or authority, and therein have vended . . . idle and malicious reports," &c. Great efforts were made to give effect to this proclamation by the infliction of punishments of atrocious severity; but when English printers were terrified into submission, Dutch printers supplied their places. News-pamphlets poured in from Holland in spite of the utmost efforts of licensers and custom-house officers, and helped to prepare the way for the downfall of the Stuarts.

Restrictions on
the news-
paper press
in 1680.

A few incidental paragraphs and announcements may deserve to be culled from the London newspapers of this period, by way of a small sample of their quality. In the fiftieth number of *Domestick Intelligencer, or News both from City and Country* (9th July, 1679), we read:—"Whereas, on Thursday the 18th instant, in the evening, Mr John Dryden was assaulted and wounded in Rose Street, in Covent Garden, by divers men unknown: if any person shall make discovery of the offenders to the said Mr Dryden, or to any justice of peace, . . . he shall not only receive fifty pounds, . . . but if the discoverer be himself one of the actors, he shall have the fifty pounds without letting his name be known, or receiving the least trouble by any prosecution." [In the present day such an advertisement as this would entail a fine of fifty pounds on the newspaper in which it appeared.] In No. 37 of *The True News* (27th March, 1680), it is announced that a project is set on foot "for conveying of letters, notes, messages, amorous billets, and all bundles whatsoever under a pound weight, and all sorts of writings (challenges only excepted), to and from any part of the city and suburbs; to which purpose the projectors have taken a house in Lime Street for a general office, and have appointed eight more stages in other parts at a convenient distance; a plot which, if not timely prevented by the freemen porters of the city, is like to prove the utter subversion of them and their worshipful corporation." *The London Gazette* of the 3d December 1683 informs its readers that "there is a considerable sum of money already paid in to Mr Child at Temple Bar, towards the lottery of the jewels of his late R.H. Prince Rupert. For the satisfaction of all such as have any doubts of the fair and equal proceeding in the drawing thereof, . . . His Majesty will be pleased publicly, in the banqueting-house, to see the blanks told over, . . . and to read the papers in which the prizes are to be written, which . . . His Majesty will mix amongst the blanks." In this instance, it will be noticed, the style of the gazetteer is sufficiently prolix to necessitate abridgment, but usually it is of the conciseness. Deeds which still sound in our ears like a trumpet are narrated in the same bald manner as are the merest trivialities of the court. Thus, No. 1884 ends with this paragraph:—"This day Algernon Sidney, Esq., was brought from the Tower to the place appointed for his execution on Tower Hill, where he was beheaded on a scaffold erected for that purpose;" and No. 1886 with the following:—"On Monday last, His Majesty and Her Royal Highness were pleased to do Sir William Jennens the honour to see his new-erected bagnio in Longacre, and very well to approve thereof."

volution of
1688.

Universal Intelligence, The English Courant, and The London Courant. Within a few days more, these were followed by *The London Mercury, The Orange Gazette, The London Intelligence, The Harlem Currant,* and others. The Licensing Act, which was in force at the date of the Revolution, expired in 1692, but was continued for a year, when it finally ceased. On the appearance of a paragraph in *The Flying Post* of 1st April 1697,¹ which appeared to the House of Commons to attack the credit of the exchequer bills, leave was given to bring in a bill "to prevent the writing, printing, or publishing of any news without license;" but the bill was thrown out in an early stage of its progress. That *Flying Post* which gave occasion to this attempt was also noticeable for a new method of printing, which it thus announced to its customers:—"If any gentleman has a mind to oblige his country friend or correspondent with this account of public affairs, he can have it for twopenne . . . on a sheet of fine paper, half of which being left blank, he may thereon write his own affairs, or the material news of the day."

The press
under
Queen
Anne.

But it was in the reign of Queen Anne that the newspaper press first became really eminent for the amount of intellectual power and of versatile talent which was employed upon it. It was also in that reign that the press was first fettered by the newspaper stamp. The accession of Anne was quickly followed by the appearance of the first London daily newspaper, *The Daily Courant* (1703), published and edited by the well-known printer Samuel Buckley, and this by a crowd of new competitors for public favour of less frequent publication. The first number of one of these, *The Country Gentleman's Courant* (1706), was given away gratuitously; and the following special pretensions were put forward on its behalf:—"Among the crowd of newspapers that come out weekly, it is hoped that this may find as favourable a reception as any, when its usefulness is rightly considered; for here the reader is not only diverted with a faithful register of the most remarkable and momentary [*i.e.*, momentous] transactions at home and abroad, . . . but also with a geographical description of the most material places mentioned in every article of news, whereby he is freed the trouble of looking into maps."

Defoe's
Review.

Shortly after the commencement of *The Daily Courant*, Defoe began his famous paper *The Review*. At first he called it *A Weekly Review of the Affairs of France, purged from the Errors and Partiality of News-Writers and Petty Statesmen of all sides*. But this long and singular title was objected to by friends and ridiculed by foes. With the eighteenth number Defoe dropped the words "of the affairs of France," although on the title-page of his second volume he returned to the original designation thus modified:—*A Review of the Affairs of France, with Observations on Transactions at Home*. At the outset it was published weekly, afterwards twice, and at length three times a week. It continued from February 1704 to May 1713; and a complete set is of extreme rarity. From the first page to the last it is characterized by the manly boldness and persistent tenacity with which the almost unaided author utters and defends his convictions on public affairs, against a host of clever and bitter assailants. He waxed very wroth at times—as well he might—but expresses his anger much oftener by incisive sarcasm than by the coarse personalities which were then so common. The work is as much marked by genial humour as by keen insight; and if in its style it lacks polish, it undeniably abounds in vigour. Especially memorable is it as the first newspaper which bears plainly on its face that the author was far more intent on making patriots than on making money. In that corner

of his paper which he entitled "Advice from the Scandalous Club," and set apart for the discussion of questions of literature and manners, and sometimes topics of a graver kind, Defoe to some extent anticipated the *Tatlers* and *Spectators* of a later day. He thus explains the purpose which he had there in view:—"As to our brethren of the worshipful company of news-writers, . . . they shall meet with no ill treatment. But if they tell a lie that a man may feel with his foot, and not only proclaim their folly but their knavery; if they banter religion, sport with things sacred, and dip their pens in blasphemy; our Scandalous Club is a new corporation erected on purpose to make inquisition of such matters, and will treat them but scurvily, as they deserve." The essays of Queen Anne's day, though in their origin they partook of the character of newspapers, open a theme too wide for the scope of this article, and more properly belong to the subject of Periodical Publications.

News-
papers.

The year 1710 was marked by the appearance of *The Examiner, or Remarks upon Papers and Occurrences* (No. 1, August 3), of which thirteen numbers had appeared by the co-operation of Bolingbroke, Prior, Friend, and King, before it was placed under the sole control of Swift, who, as Sir W. Scott has said, "not satisfied with directing his artillery on the main body of the enemy, singled out for his aim particular and well-known individuals. Wharton, whose character laid him too open for such an attack, was the first of these victims. Sunderland, Godolphin, Cowper, Walpole, and Marlborough himself, became the butts of his satire; but he is less justifiable where it is exerted against Lord Somers, whose services to his country, independent of ancient friendship and undeniable virtues, ought to have silenced such reproaches as had no better foundation than private scandal." *The Whig Examiner*, avowedly intended "to censure the writings of others, and to give all persons a re-hearing who had suffered under any unjust sentence of *The Examiner*," followed on the 1st September; and *The Medley* three weeks afterwards. In the same year a paper, entitled *The British Mercury* (No. 1, March 27), was established by the proprietors of the Sun Fire Office. In subsequently commencing a new series of this paper, its conductors prefixed a sort of summary—from their own point of view, of course—of the previous history of English newspapers. After describing the renewed activity of the press at the Revolution period, the writer proceeds:—"Such a furious itch of novelty has ever since been the epidemical distemper, that it has proved fatal to many families; the meanest of shopkeepers and handicrafts spending whole days in coffee-houses to hear news and read politics, whilst their wives and children wanted bread at home; and their business being neglected, they were themselves at length thrust into gaols. . . . Hence sprung that inundation of *Postmen, Postboys, Evening Posts, Supplements, Daily Courants, Protestant Postboys*, amounting to twenty-one every week, besides many more which have not survived to this time, and besides the *Gazette*, which has the sanction of public authority; and this *Mercury*, only intended for and delivered to those . . . insured by the Sun Fire Office. Yet has not all this variety been sufficient to satiate the immoderate appetite of intelligence, without ransacking France, Holland, and Flanders, whence the foreign mails duly furnish us with the *Gazettes* or *Courants* of Paris, Brussels, Antwerp, Amsterdam, Hague, Rotterdam, Leyden, and some others not so common, besides the French and Holland *Gazettes-à-la-Main*."

length some busy brain struck out amidst its cogitations the fertile expedient of a newspaper tax. To whom the first idea was owing is not now known. All that our parliamentary history records on this point is, that "some members in the Grand Committee of Ways and Means suggested a more effectual way for suppressing libels," &c. The immediate or ostensible occasion, it may be added, of the enactment lay simply in the publication of a Dutch state-paper by the writer of the *Daily Courant*, one of the best journals of the time. The duty imposed was a halfpenny on papers of half a sheet or less, and a penny on such as ranged from half a sheet to a single sheet (10 Ann., c. xix., § 101), and it came into force on the 19th July 1712. The first results of the tax cannot be more succinctly or more vividly described than in the following characteristic passage of the *Journal to Stella*:—"Do you know that Grub Street is dead and gone last week? No more ghosts or murders now for love or money. I plied it close the last fortnight, and published at least seven papers of my own, besides some of other people's; but now every single half-sheet pays a halfpenny to the queen. The *Observer* is fallen; the *Medleys* are jumbled together with the *Flying Post*; the *Examiner* is deadly sick; the *Spectator* keeps up, and doubles its price,—I know not how long it will hold. Have you seen the red stamp the papers are marked with? *Me-thinks the stamping is worth a halfpenny.*" It is one of the "curiosities of literature" that the first commissioner of the stamp-office was Richard Steele, who did not, however, long retain the post.

Swift's doubt as to the ability of the *Spectator* to hold out against the tax was justified by its discontinuance in the following year. But the impost which was thus fruitful in mischief, by suppressing much good literature, wholly failed in keeping out bad. Some of the worst journals that were already in existence kept their ground, and the number of such erelong increased.¹ An enumeration of the London papers of 1714 comprises *The Daily Courant*, *The Examiner*, *The British Merchant*, *The Lover*, *The Patriot*, *The Monitor*, *The Flying Post*, *The Postboy*, *Mercator*, *The Weekly Packet*, and *Dunton's Ghost*. Another enumeration in 1733 includes *The Daily Courant*, *The Craftsman*, *Fog's Journal*, *Mist's Journal*, *The London Journal*, *The Free Briton*, *The Grub Street Journal*, *The Weekly Register*, *The Universal Spectator*, *The Auditor*, *The Weekly Miscellany*, *The London Crier*, *Read's Journal*, *Œdipus*, or *The Postman Remounted*, *The St James' Post*, *The London Evening Post*, and *The London Daily Post*. Twenty years later the last-named publication became the well-known *Public Advertiser*. Nor ought it to be forgotten, that to this multiplicity of newspapers we are indebted for the foundation of that storehouse of curious information, *The Gentleman's Magazine*. The title-page of the first volume avows that it is "collected chiefly from the public papers;" and in his preface the editor remarks, that "upon calculating the number of newspapers, it is found that . . . no less than two hundred half-sheets per month are thrown from the press in London, and about as many printed elsewhere in the three kingdoms." Towards the middle of the century the provisions and the penalties of the Stamp Act were made more stringent, and the jail population largely increased by the number of offences against it. Yet the number of newspapers continued to rise. Johnson, writing in 1758, bears testimony to the still growing thirst for news:—"Journals are daily multiplied, without increase of knowledge. The tale of the morning paper is told in the evening, and the narratives of the evening are bought again

in the morning. These repetitions, indeed, waste time, but they do not shorten it. The most eager peruser of news is tired before he has completed his labour; and many a man who enters the coffee-house in his night-gown and slippers, is called away to his shop or his dinner before he has well considered the state of Europe." Five years before this remark appeared in the *Idler*, the aggregate number of newspapers annually sold in England, on an average of three years, amounted to 7,411,757. In 1760 it had risen to 9,464,790, and in 1767 to 11,300,980.

News-
papers.

The first newspaper purporting by its title to be Scotch (the *Scotch Intelligencer*,² 7th September 1643), and the first newspaper actually printed in Scotland (*Mercurius Politicus*, published at Leith in October 1653), were both of English manufacture; the one being intended to communicate more particularly the affairs of Scotland to the Londoners; the other to keep Cromwell's army well acquainted with the London news. The reprinting of the *Politicus* was transferred to Edinburgh in November 1654, and it continued to appear (under the altered title, *Mercurius Publicus*, subsequently to April 1660) until the beginning of 1663. Meanwhile, an attempt by Thomas Sydeserfe to establish a really Scottish newspaper, *Mercurius Caledonius*, had failed after the appearance of ten numbers, the first of which had been published at Edinburgh on the 8th of January 1661. It was not until March 1699 that a Scottish newspaper was firmly established, under the title of *The Edinburgh Gazette*, by James Watson, a printer of eminent skill in his art. Before the close of the year the *Gazette* was transferred to John Reid, by whose family it long continued to be printed. In February 1705 Watson started *The Edinburgh Courant*, of which he only published fifty-five numbers. In 1710 the town council authorized Mr Daniel Defoe to print the *Edinburgh Courant* in the place of the deceased Adam Bog. Four years earlier the indefatigable pioneer of the Scottish press, James Watson, had commenced the *Scots Courant*, which he continued to print until after the year 1718. To these papers were added, in October 1708, *The Edinburgh Flying Post*; and in August 1709, *The Scots Postman*. Five years later this paper appears to have been incorporated with the *Edinburgh Gazette*, and the conjoined publications appeared twice a week. In December 1718 the town council gave a privilege to James M'Ewan to print the *Edinburgh Evening Courant* (a journal which still subsists) three times a week, on condition that before publication he should "give ane coppie of his print to the magistrates." *The Caledonian Mercury* dates from the 28th of April 1720. At one period it was published thrice, and afterwards twice a week. Its first proprietor was William Rolland, an advocate, and its first editor Thomas Ruddiman. The property passed to Ruddiman on Rolland's death in 1729, and remained in his family until 1772. It now appears daily.

The early newspapers which in title and subject-matter are Irish, belong, like their Scottish contemporaries, to the newspaper press. Such, for example, are *Ireland's True Dispensary* (February 1642), and *Mercurius Hibernicus* (1644). Such also was *The Irish Courant*, published almost half a century later (No. 1, April 4, 1690); but this Revolutionary journal had been preceded by *The Dublin News-Letter*, printed in 1685, "by Joseph Ray in College Green, for Robert Thornton, at the Leather Bottle in Skinner Row;" and was followed in 1690 by *The Dublin Intelligencer* (No. 1, September 30, 1690), which was also printed

¹ See the Burney collection of newspapers in the British Museum; and Nichols, *Literary Anecdotes of the Eighteenth Century*, iv. 33-37.
² This was followed by *The Scotch Dove*, the first number of which is dated "Sept. 30 to October 20, 1643," and by *The Scottish Mercury* (No. 1, Oct. 5, 1643). In 1648 a *Mercurius Scoticus* and a *Mercurius Caledonius* were published in London. *The Scotch Dove* was the only one of these which attained a lengthened existence.

News-
papers.

by Joseph Ray. *Falkener's Journal* was established in 1728, and appeared daily. *Esdale's News-Letter* began in 1744, took the title of *Saunders' News-Letter* in 1754 (when it appeared three times a week), and became a daily newspaper in 1777. It is said still to possess the largest circulation which has ever been attained by an Irish daily paper.

Waterford possessed a newspaper as early as 1729, entitled *The Waterford Flying Post*. It professed to contain "the most material news both foreign and domestic," was printed on common writing-paper, and published twice a week at the price of a halfpenny. *The Belfast News-Letter* was started in 1737, and it still flourishes. The more famous *Freeman's Journal* was long pre-eminent amongst the Dublin papers for ability and vigour. It was established by a committee of the first society of "United Irishmen" in 1763, and its first editor was Dr Lucas. Flood and Grattan were at one time numbered amongst its contributors; although the latter, at a subsequent period, is reported to have exclaimed in his place in the Irish Parliament, "the *Freeman's Journal* is a liar, . . . a public, pitiful liar."¹ The relations between the journalism and the oratory of Ireland have been not infrequently of this stormy character.

Prosecu-
tions of the
press,
1760-1820.

The history of newspapers during the long reign of George III. is a history of criminal prosecutions, in which individual writers and editors were repeatedly defeated and severely punished; whilst the press itself derived new strength from the protracted conflict, and turned ignominious penalties into signal triumphs. From the days of John Wilkes to those of Leigh Hunt, every conspicuous newspaper prosecution gave tenfold currency to the doctrines that were assailed; and if some timid malcontents were occasionally cowed into silence and retreat, the ranks were the stronger for their absence. In the earlier part of this period, men who were mere traders in politics—whose motives were obviously base, and their lives contemptible—became powers in the state, able to brave king, legislature, and law courts, by virtue of the simple truth that a free people must have a free press. Yet the policy that had utterly failed in 1763 continued to be clung to in 1819.

Rise of
parliamen-
tary re-
porting in
the news-
papers.

One of the minor incidents of the *North Briton* excitement led indirectly to valuable results with reference to the much-vexed question of parliamentary reporting. During the discussions respecting the Middlesex election, Almon the bookseller collected from members of the House of Commons some particulars of the debates, and published them in the *London Evening Post*. The success which attended these reports induced the proprietors of the *St James's Chronicle* to employ a reporter, in their turn, to collect notes in the lobby and at the coffee-houses. This repeated infraction of the "privilege" of secret legislation, entailed the memorable proceedings of the House of Commons in 1771, with their fierce debates, angry resolutions, and arbitrary imprisonments;—all resulting, at length, in that *tacit* concession of publicity of discussion which has ever since prevailed.

Chief Lon-
don news-
papers.
1760-1820.

The three metropolitan newspapers which at different periods of this reign stood pre-eminent amongst their competitors were *The Public Advertiser*, *The Morning Post*, and *The Morning Chronicle*. The far more striking predominance of *The Times* is, as we shall see hereafter, a thing of later date. The first-named paper owed some of its popularity to the letters of Junius. The *Post* and the *Chronicle* were mainly indebted for their success (in by-gone days) to the personal qualities of individual editors.

It need hardly be said that the *Public Advertiser* was already a successful and rising journal when it published the

first contribution of Junius. To none other would the letters of Junius have been sent. Many of them had appeared before the smallest perceptible effect was produced on the circulation of the paper; but when the "Letter to the King" came out (19th Dec. 1769, almost a year from the beginning of the series), it caused an addition of 1750 copies to the ordinary impression. The effect of subsequent letters was variable; but when Junius ceased to write, the *monthly* sale of the paper had risen to 83,950. This was in December 1771. Seven years earlier the *monthly* sale had been but 47,515. The *Public Advertiser* did not, however, long retain the position into which it had been so rapidly elevated. The *Morning Chronicle* was begun in 1769. William Woodfall ('Memory' Woodfall, as he was called) was its printer, reporter, and editor; and continued to conduct it until 1789. James Perry succeeded him as editor, and so continued, with an interval during which the editorship was in the hands of the late Mr Sergeant Spankie, until his death in 1821. In the days of the "Black Acts" the *Chronicle* was the most uncompromising opponent of the government, and Perry's editorial functions were occasionally discharged in Newgate; in 1819 the daily sale nearly reached 4000. When sold in 1823 to the late Mr Clement, the purchase-money amounted to L.42,000. Mr Clement held it for about eleven years, and then sold it to the late Sir John Easthope, for a much smaller sum than it had cost him. Of its subsequent fortunes, it is enough here to say, that in 1854 its average circulation had sunk to 2791 copies daily. But no loss of popularity can deprive it of the distinction of having been the first newspaper which was adorned by literary criticism of the highest order.

News-
papers.Letters of
Junius in
the Public
Advertiser.The Morn-
ing Chron-
icle.

The *Morning Post* dates from 1772. For some years it was in the hands of the notorious 'Parson Bate' (afterwards known as Sir Henry Bate Dudley), and it attained some degree of temporary popularity, though of no very enviable sort. In 1795 the entire copyright, with house and printing materials, was sold for L.600 to Peter and Daniel Stuart, who quickly raised the position of the *Post* by enlisting Mackintosh and Coleridge in its service, and by giving unremitting attention to advertisements and to the copious supply of incidental news and amusing paragraphs. A few years ago there was a long controversy about the share which Coleridge had in elevating the *Post* from obscurity to eminence. That he greatly promoted this result there can be no doubt. His famous "Character of Pitt," published in 1800, was especially successful. It largely increased the sale of the paper, and created a demand for the particular number in which it appeared that lasted for weeks, a thing almost without precedent. Nor were newspaper-owners likely to be at all insensible to the value of talents which bore such a golden stamp. Mr D. Stuart, indeed, was once silly enough to write,—after quoting the anecdote of the city bookseller Sir Richard Phillips having slapped Coleridge on the shoulder at a dinner party, saying, "I wish I had you in a garret without a coat to your back,"—"In something like this state, I had Coleridge." But, when in a better mind, he has borne testimony on this point which is unexceptionable. To write the leading articles of a newspaper, he says, "I would prefer Coleridge to Mackintosh, Burke, or any man I ever heard of." His observations were marked by good sense, . . . extensive knowledge, deep thought, and well-grounded foresight. . . . They were the writings of a scholar, a gentleman, and a statesman, without personal sarcasm, or illiberality of any kind." But unhappily, we must add, these noble qualities lacked another. In his best days the poet-philosopher never possessed that capacity for steady, persistent, punctual labour which is the sinew of periodical literature, and for the want

The Morn-
ing Post.Newspaper
writings of
Coleridge.¹ Debates of the Irish House of Commons, 3d March 1789,

News-
papers.

of which we have all of us seen names synonymous with genius become symbols of failure. To say, therefore, that it was less to the powers of Coleridge, than to the energetic enterprise and the eminent business qualities of the new proprietors, that the *Morning Post* owed its extraordinary rise, from a daily circulation in 1795 of 350, to one in 1803 of 4500 copies, is consistent alike with the ascertained facts, and with the obvious necessities of the case.

Rapid de-
cline of the
Morning
Post after
1803.

But it may well excite some degree of wonder to find a journal which had attained such a position sinking within a very few years to a depth of degradation which carried it as far below its competitors as it had formerly risen above them. When Stuart sold his paper in 1803, with its circulation exceeding by one half that of its most popular daily rival, and with a character for honest independence which was still more enviable, he could hardly have anticipated that in 1812 he would read in its columns a poetical address "to the Prince Regent," which, for unblushing falsehood and venal adulation, might challenge the enslaved press of Austria or of Russia. "Glory of the People," "Protector of the Arts," "Mæcenas of the Age," "Conqueror of Hearts,"—such were the epithets thickly strewn in a eulogy which was wound up in this fashion:—

"Thus gifted with each grace of mind,
Born to delight and bless mankind;
Wisdom, with pleasure in her train,
Great Prince, shall signalize thy reign!"

It was for lashing this vile parasite in terms of manly indignation, and for vigorously enforcing the pregnant truth, "Flattery in any shape is unworthy a man and a gentleman; but political flattery is almost a request to be made slaves," that John Hunt and Leigh Hunt were sentenced to a fine of one thousand pounds; to be, each of them, imprisoned two years in separate gaols; and to give heavy security for good behaviour for five years more.

Repeated
augmenta-
tion of the
newspaper
tax.

Whilst the general influence of the newspaper press was becoming both more extensive, and, in the main, incomparably more civilizing, the steady industry of official persons was constantly employed in endeavours to restrain and diminish it. In 1756 an additional halfpenny had been added to the tax. In 1765 and in 1773 various restrictive regulations were imposed (5th Geo. III., c. 46; and 13th Geo. III., c. 65). In 1789 the three halfpence was increased to twopence (29th Geo. III., c. 50); in 1797 to twopence-halfpenny (37th Geo. III., c. 90); in 1804 to threepence-halfpenny (44th Geo. III., c. 98); and, in 1815, was altered to fourpence, less a discount of 20 per cent. Penalties of all kinds were also enhanced, and obstructive regulations were multiplied. Very obviously, these restrictions failed in a great degree of their immediate purpose. Yet their prejudicial effect in eking out the existence of the worst portion of the press, by fettering fair competition, is incalculable. Happily for humanity, there are, and will always be, men to whom obstacles become spurs in the career which conscience has traced for them. Their delight in the chase rises with the difficulty of the country. When once engaged in political conflict, they will, like Defoe, neither give nor take quarter.¹ But the legislation which offers to such men the widest field for their energies, multiplies the basenesses of weaker men, and gives impunity to their crimes.

Before proceeding to notice the later history of the metropolitan newspapers, it may be desirable to glance at the

rise and progress of the English provincial press. A glance at it is all that can here be attempted.

The earliest provincial paper with which we are acquainted is *The Stamford Mercury*, a publication which is still in existence, and of which its proprietors can say, with some reasonable pride, that it has appeared weekly, without interruption, for a hundred and sixty-two years. Next to this came the *Norwich Postman*, first published in 1706, in small quarto, and of meagre contents. The stated price of this paper was a penny, but its proprietor notified to the public that "a halfpenny is not refused." Two other papers were started in Norwich within a few years afterwards,—*The Courant* in 1712; *The Weekly Mercury, or Protestant's Packet* (which still exists) in 1720. Worcester seems to have been the third country town in England to boast of a newspaper; the *Worcester Postman* appearing in 1708, and the *Worcester Journal* having begun its more fortunate career (still continued) in 1709. *The Newcastle Courant* followed in 1711; *The Liverpool Courant* in 1712; the *Salisbury Postman*, and the *Felix Farley's Bristol Journal*, each in 1715; *The Nottingham Post* in 1716; and the *Kentish Post* in 1717. The *Courant* is still published at Newcastle, and the *Kentish Post* (under the altered title of *Kentish Gazette*) at Canterbury. *Farley's Bristol Journal* has merged into the *Bristol Times*. The others have long since ceased to appear.

Growth of
the English
provincial
press.

Early pa-
pers of
Norwich,
Worcester,
&c.

The *Leeds Mercury* was established in the year 1718, and, for the purpose of evading the Stamp Act, was made to extend to twelve pages, small quarto (or a sheet and a half; the stamp being then levied only on papers not exceeding a single sheet). Like its contemporaries, it was published weekly, and its price was three-halfpence. In 1729 it was reduced to four pages of larger size, and sold, with a stamp, at twopence. From 1755 to 1766 its publication was suspended, but was resumed in January 1767, under the management of James Bowley, who continued to conduct it for twenty-seven years, and raised it to a circulation of 3000. Its price at this time was fourpence. The increase of the stamp duty in 1797 altered its price to sixpence, and the circulation sank from 3000 to 800. It was purchased in 1801 by the late Edward Baines, who first began the insertion of "leaders." It took him three years to obtain a circulation of 1500; but the *Leeds Mercury* afterwards made rapid progress, and became one of the most important and valuable of the country papers, as it still continues to be.

New-Year's-Day 1719 was marked in Manchester by the appearance of the first number of the *Manchester Weekly Journal*, published by Roger Adams. This paper was followed in 1730 by the *Manchester Gazette* (afterwards called the *Manchester Magazine*), published by Henry Whitworth. *Harrop's Manchester Mercury* was begun on the 3d March 1762, and continued to exist until the close of 1830. Both of the papers last named, although alike characterized by that utter absence of literary talent which usually marked the provincial press of the period, were of violent politics, on opposite sides. The *Magazine* was Whiggish and Hanoverian; the *Mercury*, Tory and Jacobitical. A controversy, which lasted for more than a year, between the former and the *Chester Courant* (a paper that may be regarded as in some sort a continuation of the *Manchester Journal* above-mentioned, the publisher of which had removed to Chester), is not the least curious of the many episodes of the rebellion of 1745–6. It grew out of the following paragraph, which had appeared in the *Mercury* of 23d Sept. 1746:—

¹ "If I might give a short hint to an impartial writer, it would be to tell him his fate. If he resolves to venture upon the dangerous precipice of telling unbiassed truth, let him proclaim war with mankind *à la mode le pays de Pologne*—neither to give nor to take quarter. If he tells the crimes of great men, they fall upon him with the iron hands of the law; if he tells their virtues, when they have any, then the mob attacks him with slander. But if he regards truth, let him expect martyrdom on both sides, and then he may go on fear less; and this is the course I take myself."

News-
papers.

"Manchester, Sept. 22.—Last Thursday, about four in the morning, the heads of Thomas Siddal and Thomas Deacon were fixed upon the Exchange. Great numbers have been to view them; and yesterday, betwixt eight and nine in the morning, Dr Deacon, a non-juring priest, and father to one of them, made a full stop near the Exchange, and, looking up at the heads, pulled off his hat, and made a bow to them with great reverence. He afterwards stood some time looking at them."

The incident here recorded was but the spark which fell amidst a large accumulation of combustible matter. Party feeling was at that period in an especial state of excitement in Lancashire; and the paper war which followed afforded matter enough for a volume, under the title of *Manchester Vindicated: Being a complete Collection of all the Papers recently published in Defence of that Town in the Chester Courant*.

The Manchester press during the American war.

Thirty years later, the American revolution rekindled the local bigotry of faction, beneath the mask of patriotism, with even more than its former fierceness. At this period the *Manchester Mercury* published special supplements from time to time, as intelligence came from the seat of war; and whenever the news was unfavourable to the Americans, prefixed headings to the supplements, which served the double purpose of exulting in their defeat and exciting popular hatred against such of the townsmen as were known, or supposed, to regard the colonists in the light of an injured people. Thus, on the 7th January 1777, an extra sheet was published, entitled "No. 1312.—*A New Year's Gift for all true lovers of their King and Country, and a Receipt in full to the most wicked, daring, and unnatural Rebellion that ever disgraced the Annals of History, fomented and abetted by a Junto of Republicans on this side the Atlantic*." Joseph Harrop, printer of the *Manchester Mercury*, with unspeakable pleasure again presents his friends, gratis, with the following *London Gazette Extraordinary*, &c. In the next paper this paragraph was inserted:—

"We are assured by a gentleman just arrived from America, that when Washington found himself reduced to the necessity of quitting his strong entrenchments near King's Bridge, he declared that all was over with the colonies, and dropped some intimation of not wishing to survive the misfortunes of the day. . . . Mr Washington, notwithstanding his amour with Mrs Gibbons, is, we hear, married to a very amiable lady; but it is said that Mrs Washington, being a warm loyalist, has been separated from the General since the commencement of the present troubles, and lives very much respected in the city of New York."

The next supplement begins thus:—"Ye republican fomenters and abettors of rebellion, blush and tremble at your deeds." And another:—"The hour is now approaching, when all those vile republican miscreants, as well on this as on the other side the Atlantic (who have fomented . . . a most wicked and horrid rebellion against the best of kings and the best of ministers), must answer for all their mal-practices," &c.

Nor did the utter failure of these predictions teach the conductors or the patrons of the *Mercury* the wisdom of moderation. The same paper, under the same management, fostered the "Church and King" mobs of 1792; incited innkeepers to put up boards bearing the words, "No Jacobins admitted here;" and denounced all opposition to the government of the day as seditious and treasonable. When these frantic counsels had borne their natural fruit of outrage on the property and persons of reformers, the *Mercury* defended the criminals, and those who had failed to put the law in force against them, in these words:—"The fact stands thus: If any man, at such a crisis as this, will publicly make use of expressions inimical to the wellbeing of the government, under which he lives, the consequence cannot be arrested by the best-regulated police, because it will be summary." "At this time, Manchester possessed no paper of any shade of liberalism. The printing-office of the *Manchester Herald*, which had been

News-
papers.

started on the 31st March 1792, as the advocate of moderate reform, was partially destroyed by a mob in the month of December following; the local authorities of the town standing by and applauding the act; and the paper itself ceased to appear in March 1793. The *York Courant* dates its first appearance in 1719; *The Northampton Mercury* and *The Salisbury Journal* date from 1720; *The Gloucester Journal* from 1722; *The Reading Mercury* from 1723; *The Chester Courant* (already mentioned) and *The Chelmsford Chronicle* from 1730; *The Kendal Courant* appeared in 1731; *The Derby Mercury* dates from 1732; *The Sherborne Mercury* (now called *The Western Flying Post*) from 1736; *The Hereford Journal* from 1739; *Aris's Birmingham Gazette* from 1741; *The Bath Journal* from 1742; and *The Cambridge Chronicle* from 1748. The total number of existing provincial newspapers, the first publication of which is prior to 1750, is eighteen. Twenty-nine others have dates which range between the years 1750 and 1790. Most other country papers date their origin subsequently to the middle of the last century.

The Times is usually dated from the 1st of January 1788, but was really commenced on the 18th January 1785, under the title of *The London Daily Universal Register*, printed logographically. This "word-printing" process had been invented by a person named Henry Johnson's several years before, and is the subject of two patents for patents, bearing date, respectively, 9th November 1778, and 16th October 1780. The first of these is described as a "method of printing with types or figures so connected as to prevent the possibility of error in all business where figures are used, particularly in taking down the numbers of blanks and prizes in the lottery." The second is described as a "method of casting and moulding types for the purpose of composing by or with entire words, with several words combined, with sentences, and syllables, and figures combined, instead of the usual method of composing and printing with single letters," &c. These patents were Johnson's; but the invention was eagerly taken up by Mr. Walter (himself a printer), who was sanguine of its success. His *Daily Register* contained four pages, was printed on a halfpenny stamp, and was at first sold for twopence-halfpenny, afterwards for threepence. In Nos. 510 and 511 Mr Walter made a long address to the public on the advantages of the logographic plan, and of the obstacles it had encountered. "Embarked in a business," he writes, "into which I entered a mere novice, . . . want of experience laid me open to many and gross impositions; and I have been severely injured by the inattention, ignorance, and neglect of others. These reasons, though they will not excuse, will account for and palliate the errors . . . of the logographic press," &c. And he proceeds to state that the impediments thrown in his way, by the typefounders in particular, were such as to oblige him to erect a foundry for himself. In short, it is the old story of all inventors, differed in this case from many others by the circumstance, that here there were difficulties in the way of ultimate and permanent success which seem to have been really insuperable.

Another obstacle in Mr Walter's path will be best described in his own words:—

"The *Universal Register* has been a name as injurious to the *Daily logographic newspaper*, as *Tristram* was to Mr Shandy's son. Universal But old Shandy forgot he might have rectified by confirmation Register the mistake of the parson at baptism—with the touch of a bishop changed have, altered *Tristram* to *Trismegestus*. The *Universal Register*, into The from the days of its first appearance to the day of its confirmation, Times, has, like *Tristram*, suffered from unusual casualties, both laughable and serious, arising from its name, which, on its introduction, was immediately curtailed of its fair proportion by all who called for it,—the word *Universal* being universally omitted, and the word

News-
papers.

Register being only retained. 'Boy, bring me the *Register*.' The waiter answers, 'Sir, we have not a library, but you may see it at the New Exchange Coffee-House.' 'Then, I'll see it there,' answers the disappointed politician; and he goes to the New Exchange, and calls for the *Register*, upon which the waiter tells him that he cannot have it, as he is not a subscriber, and [or?] presents him with the *Court and City Register*, the *Old Annual Register*, or the *New Annual Register*. . . . For these and other reasons, the parents of the *Universal Register* have added to its original name that of the *Times*, which, being a monosyllable, bids defiance to corrupters and mutilators of the language." (*The Times, or Daily Universal Register*, printed logographically . . . for J. Walter, at the Logographic Press, Printing-House Square, &c. No. 1, 1st January, 1788.)

Within two years Mr Walter had his share in the Georgian persecutions of the press, by successive sentences to three fines and to three several imprisonments in Newgate, chiefly for having stated that the Prince of Wales and the dukes of York and Clarence had so misconducted themselves "as to incur the just disapprobation of his Majesty." In 1803 he transferred the management of the journal to his son, the late Mr Walter (together with the joint proprietorship), by whom, as is well known, it was carried on with remarkable energy and consummate tact. To Lord Sidmouth's government he gave a general but independent support. That of Mr Pitt, which succeeded, he opposed, especially on the questions of the Catamaran expedition and the malversation of Lord Melville. This opposition was characteristically resented by depriving the elder Mr Walter of the printing of the Customs department, which he had performed for eighteen years; by the withdrawal of government advertisements from the *Times*; and by the systematic detention at the outposts of the foreign intelli-

gence addressed to its editor. Mr Walter, however, was strong and resolute enough to brave the government, and to beat it. He organized a better system of news transmission than had ever before existed. He introduced steam-printing, and repeatedly improved its mechanism; *The Times* and although machines which now print 12,000 sheets in steam the hour may seem to thrust into insignificance a press of printing-press. which it was at first announced as a notable triumph that the new machine performed its task "with such a velocity and simultaneousness of movement, that no less than 1100 sheets are impressed in one hour;" yet Mr Walter's assertion was none the less true, that the *Times* of 29th November 1814 "presented to the public the practical result of the greatest improvement connected with printing since the discovery of the art itself."

The effort to secure for the *Times* the best attainable literary talent in all departments kept at least an equal pace with those which were directed towards the improvement of its mechanical resources. And thus it has come to pass that a circulation which did not, even in 1815, exceed on the average 5000 copies, became, in 1834, 10,000; in 1844, 23,000; in 1851, 40,000; and in 1854, 51,648. In the year last named, the *Morning Advertiser*, the most popular of its daily contemporaries, attained an average circulation of but 7668; whilst that of the *Daily News* was but 4160; that of the *Morning Herald*, 3712; of the *Morning Chronicle*, 2800; and of the *Morning Post*, 2667. But this extraordinary fact will be best appreciated if the average daily circulation of the *Times*, for a few years past, be compared with that of all its daily contemporaries of the London press collectively:—

The *Times* and the continental banking forgeries of 1840.

Of the many curious incidents which occur in the public history of the *Times*, one only can here be mentioned. That one is too honourable to journalism, and has been too useful in its results to the community, to be passed over. In 1840, the then Paris correspondent of this paper (Mr O'Reilly) obtained information respecting a gigantic scheme of forgery which had been planned in France, together with particulars of the examination at Antwerp of a minor agent in the conspiracy, who had been there, almost by chance, arrested. All that he could collect on the subject, including the names of the chief conspirators, was published by the *Times* on the 26th of May in that year, under the heading, "Extraordinary and Extensive Forgery and Swindling Conspiracy on the Continent (Private Correspondence)." The project contemplated the almost simultaneous presentation, at the chief banking-houses throughout the Continent, of forged letters of credit, purporting to be those of Glyn and Company, to a very large amount; and its failure appears to have been in a great degree owing to the exertions made, and the heavy responsibility assumed, by the *Times*. One of the persons implicated brought an action for libel against the printer, which was tried at Croydon in August 1841, with a verdict for the plaintiff, *one farthing damages*. A subscription towards defraying the heavy expenses (amounting to more than L.5000) which the *Times* had incurred, was speedily opened, but the proprietors declined to profit by it; and ultimately it was determined, that of the sum (L.2625) which had been raised, an amount not exceeding one hundred and fifty guineas should be expended on two commemorative tablets,—the one to be placed in the *Times* office, and the other in the Royal Exchange; the remainder of the money

being funded, and the dividends applied to the support of two "*Times*" scholarships," in connection with Christ's Hospital and the City of London School, for the benefit of pupils proceeding thence to the universities of Oxford or Cambridge. This scheme was carried into effect in 1842.

For upwards of sixty years from the establishment of the *Times*, only one of the many attempts that were made to found a new daily paper in London was successful. The most conspicuous failures were those of the *New Times* (started by Dr Stoddart, better known as "Dr Slop"); of the *Representative* (in which the late Mr John Murray risked and lost a very large sum); and of the *Constitutional* (originated by a joint-stock subscription, under the title of "The Metropolitan Newspaper Company"). All these failures were complete, notwithstanding that neither talent, industry, nor money seems to have been wanting to give the new papers a fair start. Of the latter, indeed, about L.50,000 was lost in these three unsuccessful attempts. The stamp may have had its influence in promoting these miscarriages, but the main cause of them lay in the unremitting energy, the wide forecast, and the practical wisdom with which their most formidable rival provided for and anticipated the wants of the public. The lesson is an instructive one, well deserving to be thoroughly studied by all whom it may concern.

In the exceptional case, that of the *Morning Advertiser*, the new paper attained commercial success by reason of its special character, as being at once the representative of the interests and of the charities of the Licensed Victuallers. Every publican who subscribed to it had his share in the profits. The subsequent success of the *Daily News* (the first number of which appeared in 1846), after a long and

severe struggle, has been mainly due to the ready skill with which it corrected its early blunders, and turned them to future account. Its literary staff was strong, and its enterprise, especially in relation to the early obtainment of foreign news, remarkable. For a time, too, it offered to the public a tolerably complete newspaper for twopence-halfpenny; but under the then existing circumstances this could not continue. In January 1847 the price was raised to threepence, and at this price it reached a daily sale at one time of 23,000 copies, and managed for a while to hold its own against a formidable combination of rivals. In February 1849 it resumed its original size, and was sold at the usual price of fivepence. Its average sale in 1854 was (as we have seen) only 4160. But it has always held a highly respectable place in the ranks of metropolitan journalism.

London
evening
newspapers.

London possessed no *daily* evening paper until 1788, nor did any evening paper attain an important position until the period of the war with Napoleon, when the *Courier* became the newspaper of the day. During the last three years of that war its average daily circulation reached 8000 copies. After the peace its popularity declined, and eventually a total change in its politics completed its ruin. The *Globe* and the *Sun*, as independent papers, and the *Express* and the *Evening Mail*, as offshoots respectively of the *Daily News* and of the *Times*, are now the principal journals of their class.

London
weekly
newspapers.

The London weekly press has always worn a motley garb. In its ranks are to be found some of the most worthless newspapers and some of the best. Weekly publication facilitates the individuality of a journal, both as respects its editorship, and as respects the class of readers to which it more especially addresses itself. From the days of Daniel Defoe to those of Albany Fonblanque and Robert Rintoul, there have always been newspapers bearing the unmistakable impress of an individual mind. And this characteristic quality, whilst it has strengthened and deepened the influence of good journals, has also, of necessity, increased the temporary power of bad journals. When to great force of character in the writer and its natural result, an almost personal intimacy between writer and reader, governments have been unwise enough to add the strength which inevitably grows out of persecution, the combination might well prove a formidable one. Cobbett's *Weekly Register* affords perhaps as striking an illustration of journalism, in its greatness and in its meanness, as could be culled from its entire annals since a newspaper was first issued.

Cobbett's
Weekly
Register.

When Cobbett commenced his *Political Register* in the year 1802, its plan was very different from that which he ultimately adopted. The author was at first chiefly anxious to make his work a good repository of state papers; but his point of view soon changed. What had been intended as a storehouse of materials for the future historian became a record of the varying moods of mind under which a man of remarkable powers regarded the passing events of the day. The extraordinary success of the paper was mainly owing to the vividness with which these impressions were recorded; to the clear and vigorous English, racy of the soil, in which they were clothed; and, above all, to the evidence it carried on its face that the writer, whatever his other faults, was not to be bribed, and that he meant what he said—at least whilst he was saying it. Egotism beyond all precedent, hatreds the most vindictive, and inconsistencies so numerous, that after a time opponents ceased to take note of them, were qualities in this paper so apparent that he who ran might read; and three-fourths perhaps of the topics which came under notice were discussed with a lack of information and a shallowness of thought that were quite as striking as was the blaze of light in which the writer placed the remaining fourth. To William Cobbett no question was so difficult, and no name so sacred, as to call for modest or reverent silence. Of reverence, in truth,

News-
papers.

he had none. Cobbett's French Grammar seemed to him a greater work than the *Paradise Lost*; and the chief impression he derived from the writings of Addison was, that they afforded copious examples of faulty syntax. To him all subjects were almost equally welcome, were handled with like confidence, and afforded similar opportunities for bitter personality and fierce invective. Yet the *Weekly Political Register* maintained a popularity that was almost unexampled. Cobbett carried it on during thirty-three years, and amidst all varieties of fortune. Whether he was at home or on his travels, a prisoner in Newgate or an exile in America, the work went steadily on, until it had filled 88 volumes, and then his labour ceased but with his life. He owed to it an influence that was co-extensive with the empire, and that made his name a household word at the hearths of tens of thousands who had never set eyes upon him. But if it be asked, what was the real outcome of all this rare energy and untiring industry, in the way of enlightening and elevating that numerous public whose ear it had gained, a truthful answer will be a sad one. Here and there it set a-thinking men who had capacity enough to seek further and better instruction elsewhere; but to a large proportion of its readers, the *Register* became a sort of political gospel. Nor is it uncharitable to say, that some of the worst excesses of "Chartism"—its bigotry and rancour, its short-sighted obstruction of social improvements, and its obstinate pursuit of courses leading to riot and outrage—are partly ascribable to the one-sided teachings and the frantic violence of the *Weekly Register*. Misgovernment, indeed, was the seed-plot; but these were potent fertilizers. Whatever else may have been wanting to insure a large crop was amply afforded by the results of the pertinacious maintenance of the newspaper stamp, and of those other impediments which then so thickly studded the path of every temperate and truth-loving writer who sought to address himself to the masses of his countrymen, without either flattering their vanity or exciting their passions.

The manifest incongruity between the maintenance of "taxes on knowledge" and the pretensions of a reforming government, gave a strong impulse to the violation of the law. Between the years 1831 and 1835 many scores of unstamped newspapers made their appearance. *Poor Man's Guardians*, *Twopenny Dispatches*, *Destructives*, *People's Conservatives*, *London Democrats*, and a host of other penny and halfpenny papers swarmed from presses that seemed to rival, in their mysterious itinerancy and sudden vanishings, the famous Marprelate press of the sixteenth century. The political tone of most of them was fiercely revolutionary. Some of them taught Marat's doctrine that the shortest and surest path to political amelioration lies through a sea of blood. Those of the latter class were characterized by Lord Brougham (when under examination in a committee of the House of Commons on the libel law), as competing one with the other in the ferocity of their writings. "Where one," he says, "charged public characters with all offences, another recommended their extirpation; where one maintained the lawfulness of rebellion, another maintained the propriety of assassination." Prosecution after prosecution failed to suppress the obnoxious publications. The total number of such prosecutions exceeded 700, and nearly 500 persons suffered imprisonment in the course of them. But the law continued to be systematically broken.

To Sir Edward Bulwer Lytton is due the credit of having grappled with this question in the House of Commons, in a manner which secured the speedy reduction of the tax from fourpence to a penny, and paved the way towards its subsequent though long-delayed abolition. This reduction took effect on the 15th September 1836. At that date the number of newspapers stamped in Great Britain and Ireland was about 36,000,000 in the year, and the gross amount of duty upwards of L.553,000. Of this sum English news-

Final re-
peal of the
compulsory
stamp-duty
in 1855.

The penny stamp, so far as it was compulsory, was at length entirely repealed by an act of Parliament, which received the royal assent on the 15th of June 1855. Mr Milner Gibson had, in the previous session, carried a resolution of the House of Commons affirming "that it is the opinion of this House that the laws in reference to the periodical press and newspaper stamp are ill defined and unequally enforced; and it appears to this House that the subject demands the early consideration of Parliament." This resolution necessarily brought the subject under the attention of the government, and especially of Mr Gladstone, then chancellor

of the exchequer. That minister did not retain office long enough to introduce his measure into Parliament; but his successor took up the bill he had prepared, and with some modification carried it into a law. It continued to be practicable to stamp newspapers for transmission by post; and in respect of all newspapers any part of the impression of which should be so stamped, the existing regulations as to the declaration, registration, and recognisances of newspaper proprietors remained in force. In the course of the debates the chancellor of the exchequer acknowledged that the question had become "not simply a question whether we

papers.

Lord Mont-
eagle's pro-
test against
the repeal.

shall retain or shall not retain a revenue of L.200,000,"— (this was said on the assumption that about one-half of the net revenue arising from the stamp would continue to be received),—"but it is whether we shall enter upon a crusade against a large portion of the existing newspaper press, for the sake of enforcing a law which can only be enforced by means of the verdicts of juries, which are somewhat doubtful in their result." Mr Drummond amused the House after his fashion with a summary of the history of the newspaper press, as it shaped itself to his fancy, in the course of which he said that the writers in the *Times* "reminded him a good deal of what they called on board ship a 'handy-billy,'—a tackle that came in upon all occasions whenever it was wanted;" and also, "of a bit of bog he had near a farm of his: He once thought of draining it, and asked the opinion of the farmer, who replied,—"No, no! don't drain it; in wet weather there's something for the cow; and if there's nothing for the cow, there's something for the pig; and if there's nothing for the pig, there's something for the goose." So it was with the *Times*; if there was nothing in it for one man, there was sure to be something for another." In the division at the second reading, taken on an amendment professedly for delay, but substantially intended to defeat the measure, the ayes were 215, the noes 161, the majority 54. In the House of Lords no division took place; but Lord Monteaule recorded a protest against the bill, grounded partly on fiscal objections, and partly on the assertion that the proposed remission, "so far from being sought for as a relief to the class of newspaper proprietors whose interests are primarily involved in the question, is, on the contrary, earnestly deprecated by them as being likely to lead, through an unjust and unchecked piracy, to the depreciation of their capital and the sacrifice of their com-

mercial interests." It was pertinently rejoined by Lord Canning:—"This in no way affects the justice of the question. It will be remembered that not many shipowners petitioned for the alteration of the navigation laws, nor many farmers for the repeal of the corn laws."

Thus was struck out from the statute-book a law which had been thrust upon it at a time of unusual excitement, in opposition to the counsels of the best statesmen of the day, but which, nevertheless, continued in force for a hundred and forty-three years. During that long term it uniformly showed itself to be potent for mischief, and powerless for good. Any period of unusual stringency in the execution of it was invariably marked by rampant misgovernment, crowded gaols, and wide-spread discontent. At length the contrast between professions of anxiety for the promotion of popular education, and an obstinate perseverance in impeding the progress of one of the most efficient of popular educators, became too glaring to be longer endured. It deserves to be remembered, that at this final stage, although there was a formidable array of maintainers of the stamp, not one of the number was bold enough to avow any sympathy with the reasons for supporting it which had so often been candidly asserted by writers like L'Estrange, and by statesmen like North and Pitt. In these days no politician has either fear or dislike of an unshackled press. His only alarm is, lest in losing its fetters, it should lose its character.

The interval since the repeal is as yet too brief to afford materials for any satisfactory estimate even of the immediate results. We close this section of the subject, therefore, with a brief statistical statement of the present position of the British newspaper press; first, however, prefixing a tabular summary of the operation of the stamp duty at various periods of its existence.

1 Inclusive of prices current, trade lists, &c., and of halfpenny stamps for supplements.

News-
papers.

The number of newspapers commenced from the early part of 1855, when the repeal of the stamp duty had become a certainty, although not actually accomplished, and which continued to be in existence at the beginning of 1857, amounts to 107. Eighty of these were started in 1855, and twenty-seven in 1856; twenty-six are metropolitan, and eighty-one provincial. Of the latter, the majority belong to towns which possessed no newspaper whatever under the compulsory stamp act, and the price of nearly one-third of them is but a penny. In some cases, however, a portion of these new cheap papers is printed in London, usually with pictorial illustrations, and to this is added a local supplement containing the news of the district.

Number of
newspapers
current in
1857.

The total number of the newspapers published throughout the United Kingdom at the beginning of 1857 was 711; and they may be classified as follows:—

Newspapers of	England.		Wales.	Scotland.	Ireland.	Isle of Man and Chan. Islands.	Total.
	Metro-politan.	Pro-vincial.					
Liberal politics.....	40	134	7	66	38	4	289

Postal
transmis-
sion of
newspapers
in
1855 and
1856.

The decrease in the number of newspapers which passed through the post-office in the year 1855 (during exactly one-half of which the compulsory stamp had been abolished), amounted to about one-fourth of the aggregate number which had been posted in the preceding year. During the six months of the optional stamp the money received for impressed stamps was about L.93,000, and that for postage stamps affixed on newspapers about L.25,000. In the year 1856 the number of newspapers which passed through the post-office was nearly 71,000,000, and of these about three-fourths bore the impressed stamp, and one-fourth was franked by the ordinary postage stamps. The total gross revenue was therefore about L.295,833. Prior to the abolition of the compulsory stamp the average weight of the newspapers passing through the post-office was three ounces and a half. It is now about two ounces and three-quarters. The reduction is due to the increase of the small and cheap papers. It is understood that *The Times* stamps about forty per cent. of its entire impression, the daily average of which exceeds 60,000. It need hardly be added that the alteration of the law, and the consequent multiplication of the cheaper newspapers, have diminished

neither the circulation nor the well-earned influence of the leading journal.

The establishment of a newspaper still requires compliance with most of the regulations of the 6 and 7 Will. IV., c. 76. Notice must be given at the Inland Revenue Office in London, or at the district stamp-office in the country, of the contemplated publication, with particulars of (1.) title; (2.) precise locality of printing and publishing offices; (3.) names in full of printers and publishers; (4.) number of shares held by each proprietor, if there be more than one, with their names, occupations, and places of abode. This declaration must be made by the proprietor or by the proprietors jointly, if not exceeding two; if otherwise, then by the two largest shareholders. The security of two sureties (L.400 in London, L.300 in the country) is still required as a provision against the infraction of the libel law. Each paper must bear the printer's and publisher's name as heretofore, and a copy must be deposited at the stamp-office (for which payment is made). The impressed stamp carries the paper bearing it through the post-office for any number of re-transmissions, if within fifteen days of publication. Afterwards it is subject to the ordinary regulations of the book-post. To entitle newspapers to transmission to the colonies or to foreign countries, they must, in addition to the payment of postage, according to the ordinary rates, be specially registered, and an annual fee of five shillings must be paid, which is due on the 15th June in each year. II.—THE NEWSPAPERS OF THE UNITED STATES OF AMERICA.

Boston was the first city of America that possessed a local newspaper; but the earliest attempt in that direction, made in September 1690, was suppressed by the authorities. So far as is now known, the only copy of this pioneer of the vast newspaper press of the United States which escaped destruction, is the copy that may still be seen in the State Paper Office in London. It is a small quarto sheet, one of the four pages of which is blank; the other three contain a record of passing occurrences, not unlike the contemporary news of the English press; and with little on the face of it to justify, in any sense, the assertion that "it contained reflections of a very high nature." Although it purports to be "printed by Richard Pierce for Benjamin Harris," it is probable that the latter was both printer and editor, as he had already been of a London paper, and was again at a subsequent period. Nearly fourteen years afterwards (April 24, 1704), the first number of the *Boston News-Letter* was "printed by B. Green, and sold by Nicholas Boone;" but its proprietor and editor—so far as it can be said to have had an editor, for extracts from the London papers were its staple contents—was John Campbell, postmaster of the town. In 1719 he enlarged his paper, in order, as he told his readers, "to make the news newer and more acceptable; . . . whereby that which seem'd old in the former half-sheets becomes new now by

News-
papers.

the sheet. . . . This time twelvemonth we were thirteen months behind with the foreign news beyond Great Britain [or, in other words, the attention of the Bostonian politicians was engrossed on the siege of Belgrade, when their contemporaries in the mother country were intent on the destruction of the Spanish fleet on the coast of Sicily]; and now less than five months; so that . . . we have retrieved about eight months since January last;" and he encourages his subscribers with the assurance that if they will continue steady "until January next, life permitted, they will be accommodated with all the news of Europe . . . that are needful to be known in these parts." But Campbell's new plans were soon disturbed by the loss of his office, and the commencement of a new journal by his successor in the postmastership, William Brooker, entitled the *Boston Gazette*, "published by authority" (No. 1, 21st December 1719). The old journalist had a bitter controversy with his rival, but at the end of the year 1722, relinquished his concern in the paper to Benjamin Green, by whom it was carried on with higher aims and greater success. The following passage from an address to his readers (7th March 1723), may deserve quotation:—

Green's
editorship
of the Bos-
ton News-
Letter.

"The design of this paper is not merely to amuse the reader, much less to gratify any ill-temper by reproach or ridicule, to promote contention, or espouse any party among us. The publisher, on the contrary, laments our unhappy and dangerous divisions, and he would always approve himself as a peaceable friend and servant to all. . . . He longs for the blissful times when wars shall cease to the end of the earth. . . . The publisher would therefore strive to oblige all his readers by publishing those transactions that have no relation to any of our quarrels. For this end he proposes to extend his paper to the history of nature among us, as well as of political and foreign affairs. . . . That so this paper may in some degree serve for the *Philosophical Transactions of New England*, as well as for a political history; and the things worthy of recording in this, as well as in other parts of the world, may not proceed to sink into eternal oblivion, as they have done in all the past ages of the aboriginal and ancient inhabitants."

Green conducted the paper until his death, at the close of 1733, and was succeeded by his son-in-law, John Draper, who published it until December 1762. By Richard Draper, who followed his father, the title was altered to *Massachusetts Gazette and Boston News-Letter*; and the maintenance of the British rule against the rising spirit of independence uniformly characterized his editorship and that of his widow (to whom, at a subsequent period, a pension was granted by the British government). It was the only paper printed in Boston during the siege, and ceased to appear when the British troops were compelled to evacuate the city.

The Boston
Gazette.

Franklin's
New Eng-
land Cou-
rant.

The *Boston Gazette* began, as we have seen, in 1719. James Franklin, elder brother of the statesman, was its first printer. It lasted until the end of 1754; its editorship usually changing with the change of the postmasters. On the 17th August 1721, James Franklin started the *New England Courant*, now memorable for its connection with his illustrious brother. It was soon embroiled in a religious controversy, occasioned by the opposition of the clergy to the practice of inoculation. Many of Franklin's early writings are to be found in its columns; and in February 1722 he assumed its management, James Franklin having been forbidden by the General Court of Massachusetts "to print or publish the *New England Courant*, or any other pamphlet or paper of the like nature, except it be first supervised by the secretary of this province." "The main design of this paper," said the new editor, "will be to entertain the town with the most comical and diverting incidents of human life, which, in so large a place as Boston, will not fail of a universal exemplification. Nor shall we be wanting to fill up these papers with a grateful interspersion of more serious morals, which may be drawn from the most ludicrous and odd parts of life." The publication of the *Courant* ceased in 1727; and two years later Franklin

News-
papers.

established the *Pennsylvania Gazette*, which he continued weekly until 1765. But for his subsequent fame, both of these papers would perhaps have been utterly forgotten, although their pages might afford useful contributions towards a knowledge of the manners and condition of New England in that day.

To the *Boston Gazette* and the *Courant* succeeded the *New England Weekly Journal* (20th March 1727; incorporated with the *Boston Gazette* in 1741); and the *Weekly Rehearsal* (27th September 1731), which became the *Boston Evening Post* (August 1735), and under that title was for a time the most popular of the Boston newspapers. It aimed at neutrality in politics, and therefore did not survive the exciting events of the spring of 1775.

Several minor papers followed, which may be passed over without notice. A new *Boston Gazette*, which began in April 1755, has, however, claims to be particularized. For a long time it was the main organ of the popular party, and expounded their policy with great ability, and in a dignified temper. Otis, John Adams, Samuel Adams, and Warren were amongst its writers. In January 1775 John Adams began the famous "Letters of Novanglus," the

Ede's Bos-
ton Ga-
zette.

Letters of
Novanglus.

origin of which he has himself (in his Diary) described in these words:—"About this time Draper's paper in Boston swarmed with writers, and among an immense quantity of meaner productions appeared a writer (Daniel Leonard) under the signature of 'Massachusettensis.' . . . These papers were well written, abounded with wit, discovered good information, and were conducted with a subtlety of art and address wonderfully calculated to keep up the spirits of their party and to depress our's; to spread intimidation, and to make proselytes among those whose principles and judgment give way to their fears. . . . Week after week passed away, and these papers made a very visible impression on many minds. No answer appeared. . . . I began at length to think seriously of the consequences, and to write under the signature of 'Novanglus;' and continued every week in the *Boston Gazette*, until the 19th of April 1775. The last number was prevented from impression by the commencement of hostilities, and Mr Gill gave it to Judge William Cushing, who now has it in manuscript. An abridgment of the printed numbers was made by some one in England, unknown to me, and published in Almon's *Remembrancer* for 1775, and afterwards reprinted, under the title of *History of the Dispute with America*. In New England they had the effect of an antidote to the poison of 'Massachusettensis.'" This last-named writer spoke more truly than he knew, when he said in reply,—"The changes have been rung so often upon oppression, tyranny and slavery, that whether sleeping or waking, they are continually vibrating in our ears."

The *Massachusetts Spy*, under the indefatigable editorship of the American historian of printing, Isaiah Thomas, did yeoman's service in this struggle, although of a different kind from that of the *Boston Gazette*. The latter spoke chiefly to the thinkers and natural leaders of the people. The *Spy* was a light and active skirmisher who engaged his antagonists wherever he met them, and frequently carried the war into the enemy's country. The *Massachusetts Spy* began its career in July 1770, and had for a considerable time less than 200 subscribers. To its title were added the words "A weekly political and commercial paper, open to all parties, but influenced by none." But the progress of misgovernment, and the energies of its editor's own character, soon led to a change in this respect, which was sufficiently indicated by the introduction of a motto from *Cato*:—

Thomas'
Massachu-
setts Spy.

"Do thou, great Liberty, inspire our souls,
And make our lives in thy possession happy,
Or our deaths glorious in thy just defence."

In July 1774, during the operation of the Boston Port Bill, and soon after the landing of four British regiments,

News-
papers.

Franklin's odd device was adopted, representing Great Britain as a dragon, and the colonies as a snake divided into nine parts, with the motto, "join or die." But Boston grew too hot for the patriotic printer, and he had to remove to Worcester on the day of the battle of Lexington. Here the paper continued to be published until 1786; the lack of the stirring revolutionary matter being occasionally supplied by the republication in its columns of entire books, such as Robertson's *America* and Gordon's *History of the Revolution*. But this journal, like so many more, was for a time killed by a tax. The stamp duty imposed in March 1786, though amounting to but two-thirds of a penny, and very speedily repealed, led to the suspension of the *Spy* until April 1788. At that period it was resumed; and it still continues, being the oldest newspaper in Massachusetts.

Numerical
strength of
the Ameri-
can press
at the Re-
volution.

At the commencement of the struggle for independence in 1775, Massachusetts possessed 7 newspapers, New Hampshire 1 (founded in 1756, and entitled the *N. H. Gazette*), Rhode Island 2, and Connecticut 3; making 13 in all for the New England colonies. Pennsylvania had 8, of which the earliest in date was the *American Weekly Mercury* (No. 1, 22d December 1719); and New York but 3, the oldest of them being the *New York Gazette*, the publication of which had commenced on the 16th October 1725. Up to that period (1725) Boston and Philadelphia were the only towns possessing a newspaper throughout America. In the middle and southern colonies there were (in 1775), in the aggregate, 10 journals, of which Maryland, Virginia, and North Carolina, possessed each 2, South Carolina 3, and Georgia 1. The total number of the Anglo-American papers was 34, and all of them were of weekly publication.

Summary
of the New
England
press.

The *New Hampshire Gazette* still exists, and is the "father" of the American press. In 1810 this State possessed 12 papers; in 1828, 17; in 1840, 27; in 1850 (the date of the last census), 32,—viz., 22 described as "political," and 10 as "miscellaneous." The earliest paper established in Vermont was the *Green Mountain Postboy*, first published in April 1781. In 1850 the number of newspapers was 30; 27 of which are described as "political." Maine possessed in 1850, 29; 4 of them of daily publication. Rhode Island had 13, of which 5 were daily; Connecticut had 28, including 7 daily papers; Massachusetts possessed in 1850 no less than 91 newspapers, with a collective circulation of 222,087 copies, and an aggregate circulation amounting in the year to 46,587,000. Of these, about two-thirds were published in Boston. Of the whole number, 22 were of daily, 4 of tri-weekly, 11 of semi-weekly, and 54 of weekly publication.

Press of
Pennsyl-
vania,

Pennsylvania had in 1810, 71 newspapers, and in 1850, 210, with a collective circulation of 338,336 copies, and an aggregate circulation, in the whole year, amounting to 59,717,508 copies.

The *Aurora* was the most notable of the early Philadelphia papers, next to Franklin's *Gazette*. Its hostility to federalism, and to Washington as the main pillar of the federalists, was so violent that, on the termination of his presidency, it sung so loud a *Nunc dimittis* as to excite a riot, in which its printing-office was destroyed. The *Daily National Gazette*, started in 1820, soon became prominent for its union of literature with politics. The total number of journals, political and literary, published in Philadelphia, in 1856, was 76, 12 of which were of daily publication.

and of New
York.

In New York, the *Gazette* already mentioned was followed by the *Weekly Journal* (No. 1, 5th November 1733), still memorable for the prosecution for sedition which it entailed on its printer, John Peter Zenger, and for the masterly defence of the accused by Andrew Hamilton. "The trial of Zenger," said Gouverneur Morris, "was the germ of American freedom." Gaines's *New York Mercury* was published from 1752 to 1783. Rivington's *Royal Gazette* was

established in 1773, and in the first year of its existence is said to have attained a circulation of 3600. After the Revolution this paper was continued under the title *New York Gazette, and Universal Advertiser*. The first daily newspapers published in the city or State of New York was *The New York Journal and Register*, commenced in 1788. In 1810 the aggregate number of papers published within the State was 66, of which 14 belonged to New York city. Ten years later the city press included 8 daily journals, with an aggregate daily circulation of 10,800 copies. No one paper circulated more than 2000, and but two—the *Evening Post* and the *Commercial Advertiser*—attained that number. Both the papers last named continue to flourish. In 1832 there were 13 daily journals, with a collective daily circulation of 18,200; or, on the average, 1400 to each paper. In 1850 the number of daily papers (according to the census returns) was 51, with an aggregate annual circulation of 63,928,685, which will give an average daily issue of 3942 to each of them.

News-
papers,
Daily
papers of
New York
at various
periods.

The penny press of America began in New York, and the pioneer was the *Daily Sun* (No. 1, 23d September 1833), written, edited, set up, and worked off, by B. F. Day, a journeyman printer. Its circulation at first was 600 copies. In 1854 its average issue was 36,525 copies. Its success has been described with sufficient significance as mainly owing to "piquant police reports," at least at the outset. When sold, it fetched £50,000. The profit arising from its advertisements has been stated by Mr Horace Greeley to amount to £60 a day. The notorious *New York Herald* is also a penny paper; was started in 1835 (at first at a halfpenny); and its average circulation in December 1854 was 36,158. The *New York Tribune* was established in 1851 by Mr Horace Greeley, who is still its editor. Its circulation in 1851 was 19,000 copies, of which somewhat more than half was sold within the limits of the city. It has now a daily circulation of about 29,000 copies, and, in addition, issues as a weekly paper 163,000 copies, irrespectively of certain special issues for California and for Europe. These are amongst the prizes of New York journalism. How numerous the blanks are may be inferred from the statement, that between the years 1820 and 1850, 32 daily newspapers were founded and abandoned.

Elaborate as are the returns given in the United States' census in relation to this subject, they are only to be relied upon for precise information respecting newspapers when limited to those of daily issue. The classification of the main returns which bear on the matter is headed, "How often issued;" and, although there is a subsidiary classification headed "Character," it fails to elicit even the simple distinction between newspapers and magazines. This classed arrangement comprises—(1.) "Literary and Miscellaneous;" (2.) "Neutral and Independent;" (3.) "Political;" (4.) "Religious;" (5.) "Scientific." If, however, we understand the second division as meaning periodicals of "Neutral and Independent" politics, the entire newspaper press of the State of New York in 1850 may be summed up thus:—

Character	No. of Papers.	Average Circulation.	Aggregate An- nual Circulation
"Neutral and Independent" Newspapers.....	15	127,370	37,317,010
Newspapers attached to a political party.....	263	399,755	45,463,015
Total of the Newspaper press.	278	527,125	82,780,025

General
statistics of
the news-
paper press
of New
York.

The total number of newspapers published in Maryland, in 1850 was 40, Delaware had 10, and New Jersey 45. The last-named State had no local paper before the Revolution, although a single number of one had been

News-papers. published in 1765, under the title of the *Constitutional Gazette, containing Matters interesting to Liberty, but no wise repugnant to Royalty*. The earliest regular paper was the *New Jersey Gazette*, which began in December 1777. The total number of newspapers in the Middle States at the date of the census (estimated as in the case of New York) may be taken at 583, exclusive of periodicals of a distinctly literary, theological, or scientific nature.

Newspapers of the Southern States. In the Southern States, the annals of newspapers, as of so much else, may be far more compactly dealt with than is possible in regard to the Northern and Middle States. Virginia, notwithstanding its precedence, possessed neither newspaper nor printing-office until 1736; so that (as respects one-half at least of the wish) there was once a prospect that the devout aspiration of Sir William Berkley might be realized. "Thank God," said this Virginian governor in 1671, "We have neither free school nor printing-press, and I hope may not have for a hundred years to come." The Virginia papers occasionally present to modern readers figures of Liberty at their head (sometimes with a banner,

inscribed "*Drapeau sans tache*"), whilst in the body of the journal comes a string of advertisements headed "Cash for Negroes." Those who love America best may perhaps be apt to think that Sir W. Berkley's words would make as appropriate a motto. This great question apart, several of the Virginia papers have evinced considerable ability and independence of spirit. The earliest journal established in the State was the *Virginia Gazette*, commenced in 1736. The *Richmond Inquirer*, which started in 1804, early attained a leading position. In 1810 the total number of Virginian papers was 23; in 1828, 37; at the census of 1850, 67; with an average total circulation of 56,188 copies. North Carolina, at the last-named date, possessed 37 newspapers, with an average total circulation of 25,439; South Carolina, 29, with a similar circulation of 36,415; Georgia, 26, with 23,346; Florida, 7, with 3500; Alabama, 46, with 25,336.

The statistics of the newspaper press of the entire Union may be thus epitomized, so far as respects the two classes designated in the census "Neutral" and "Political":—

III.—THE NEWSPAPERS OF FRANCE.

The long and eventful annals of French journalism Renaudot's begin with the *Gazette* established by Théophraste Renaudot in 1631, under the patronage of Richelieu, and very probably with his active co-operation. Renaudot was born at Loudon in 1584; studied medicine in Paris, and afterwards at Montpellier, where he took his degree; established himself in the capital in 1612, and soon became conspicuous both within and beyond the limits of his profession. Endowed by nature with great energy and versatility of talent, he seems at an early period of his career to have attracted the attention of the great Cardinal, and to

News-
papers.

have obtained permission to establish a sort of general agency office, under the designation of "*Bureau d'Adresses et de Rencontre*." An enterprise like this would, perhaps, naturally suggest to such a mind as Renaudot's the advantage of following it up by the foundation of a newspaper. According to some French writers, however, the project was formed by Pierre d'Hozier, the genealogist, who carried on an extensive correspondence both at home and abroad, and was thus in a position to give valuable help; according to others by Richelieu himself. Be this as it may, Renaudot put his hand zealously to the work, and brought out his first weekly number in May 1631. So much, at least, may be inferred from the date (4th July 1631) of the sixth number, which was the first *dated* publication; the five preceding numbers being marked by "signatures" only—A to E. Each number consists of a single sheet (eight pages) in small quarto, and is divided into two parts—the first simply entitled "*Gazette*," the second "*Nouvelles Ordinaires de Divers Endroits*." For this division the author assigns two reasons—(1.) That two persons may thus read his journal at the same time; (2.) That it facilitates a division of the subject-matter—the *Nouvelles* containing usually intelligence from the northern and western countries, the *Gazette* from the southern and eastern. He commonly begins with foreign, and ends with home news,—a method which was long and generally followed, and which still obtains. Once a month he published a supplement, under the title of *Relation des Nouvelles du Monde reçues dans tout le Mois*. "These monthly *Relations* of mine," he says, "serve to epitomize and to correct the weekly ones. For it is with news as with metals—when they come first from the mine, the metals are mixed with earth. In like manner, news are at the outset usually accompanied by mistakes and misconceptions, from which in a little time they get separated, just as the metals lose their dross in the furnace. Then you get them pure."

In October 1631, Renaudot obtained letters-patent to himself and his heirs, conferring the exclusive privilege of printing and selling, where and how they might please, "the gazettes, news, and narratives of all that has passed or may pass within and without the kingdom—" . . . [In the beginning of this document he had been designated "Master and General Intendant of the Address Offices of the Kingdom;" and these offices are directly connected with the *Gazette* by the addition, after the words we have quoted, of what follows—] "conferences, prices-current of merchandise, and other printed matter of the said offices (*autres impressions des dits bureaux*). At the end of the year, he collected his thirty-one numbers into a volume, and published them under the title, *Recueil des Gazettes de l'Année 1631*; prefixing also a preface to the public, and a dedication to the king. In the former he says,—

"The publication of gazettes is in truth new; but this novelty may win for them a favour which they will easily preserve. They will be maintained for their utility, both to the community and to individuals;—to the community, by preventing those false reports which often serve to kindle turmoils and seditions; to individuals, by enabling every man to adjust his business according to the needs of the time. Thus the merchant will not betake himself for traffic to a besieged or ruined city, nor will the soldier seek for service in a country which is at peace,—to say nothing of the advantage they will bring to those who have to write to friends, whose curiosity they had heretofore to satisfy with news, often invented for the occasion, or founded on the guess-work of mere hearsay." . . . "The difficulties," he adds, "which I mention as attendant on the composition of my *Gazettes* are not put forward for the glorification of my work, but as an excuse for my style, if it does not always correspond with the dignity of my themes. . . . Captains wish to have news of battles and sieges every day; lawyers to have law reports; devout persons to meet the names of favourite preachers and confessors. Some people, who understand nothing of the secrets of the court, wish to have them exposed at full length. Others are angry if their names do not meet the king's eye in the *Gazette*, for having bought the reversion of some

unimportant office, or for having safely conveyed a state parcel. . . . Some attach value to nothing but flowery language; others would have my narratives resemble a bare skeleton. . . . Can you then, my reader, deny me your pity, or withhold your pardon, if my pen fail to please everybody, hold it as I may; any more than could the peasant and his son, in the fable, although they travelled first singly, and then together,—at one time a-foot, and at another on the ass? . . . Yet I should deceive myself were I to hope to curb your censure by my remonstrances. I cannot do it, and ought not, reader, if I could. The liberty to find fault is not the least of the pleasures attendant on reading of this sort; and it is for your pleasure that this novelty has been invented. Enjoy, then, at your ease your French liberty; and let every one say boldly that he would take away this, or change that, and that he could have done much better. I admit it. In one thing only I will yield to nobody—in the search after truth, though I will not vouch for its constant attainment."

Renaudot's assailants were numerous, and made full use of "French liberty." Many, too, were the parodies by which it was sought to throw ridicule upon his enterprise. But he steadily pursued his course, rarely noticed his assailants, and at his death in October 1653, left the *Gazette* to his sons in flourishing circumstances. In 1752 the title "*Gazette de France*" was first used. Under this designation it continued to appear until the 24th August 1848. During the five memorable days which followed that date it was suspended; on the 30th it was resumed as *Le Peuple Français, Journal de l'Appel à la Nation*; and again modified on the 14th September to *L'Etoile de la France, Journal des Droits de Tous*. On the 25th October it became *Gazette de France, Journal de l'Appel à la Nation*; and under this title it still continues to appear. A complete set extends to upwards of 300 volumes, of which 189 are in quarto, and the rest in folio. It scarcely need be added that such a set forms a collection of great value, not only for the history of France, but for that of Europe generally.

We pass over a group of *Couriers* (*Le Courrier Français, Le Courrier de la Cour, Le Courrier Burlesque, Le Courrier Bourdelais*, &c.), which properly form part of the extraordinary collection of pamphlets usually termed *Mazarinades*. Most of these *Couriers* belong to the year 1649, but they are not serial newspapers. They come within the same category as the English news-pamphlets mentioned in a preceding section of this article.

In 1650, Paris had its newspaper in verse. Loret, the "courtier-poet," as he has been called, began this flimsy but amusing, and now not uninteresting periodical, for the gratification of his patroness, Mademoiselle de Longueville.

"Pour complaire à ses volontés,
Et mieux mériter ses bontés."

But the new Gazetteer was too witty, and too incisive in his stroke, to be long confined to the narrow though brilliant circle of the Hotel de Longueville. MS. copies were obtained, sometimes surreptitiously, sometimes by dint of pertinacious application. At length, after it had circulated from hand to hand for nearly two years and a half, some numbers were furtively printed under the title *La Gazette du Temps, en Vers Burlesques*.

"Des débiteurs de faux papiers,
Pires cent fois que des fripiers,
Faisaient imprimer ses gazettes,
Sans craindre ni loi ni syndic
Pour en faire un lâche trafic."

The poor poet was fain to follow the example. He consoles himself by the reflection that the copies in MS. were always faulty, and gravely assures his readers that "printing is an excellent invention for producing simultaneously several copies of a work." Resuming his verse, however, he proceeds:—

"Mais sache, lecteur débonnaire,
Encor que des mains du rimeur
Cette gazette épistolaire
Passe en celles de l'imprimeur,

Qu'elle n'en est pas plus commune;
Car, sans abus ni fraude aucune,
Il doit observer cette loi
De n'en tirer chaque semaine,
Qu'une unique et seule douzaine,
Tant pour mes amis que pour moi;
Après cela point de copie,
En dût-on avoir la peupie."

The usual title of each Gazette, as printed by the author, is *Lettre en vers à Son Altesse Mlle. de Longueville*; but in 1656 he collected them under the title *La Muse Historique, ou Recueil des Lettres en Vers écrites à S. A. Mlle. de Longueville, par le Sieur Loret*. Livre premier. Dedié au Roi (Paris, 1656, 4°). He continued the task almost until the day of his death, in April 1665. His last letter ends with this sad couplet:—

"Le vingt-huit Mars j'ai fait ces vers,
Souffrant cinq ou six maux divers."

The first complete edition appeared in 1658; and the words "Contenant les nouvelles du temps," are added to the title above mentioned.

Loret's *Gazette* will always have interest in the eyes of students, who care less for the "dignity" of history than for the fidelity of its local colouring, and the animation of its backgrounds, if we may so speak. It were as vain to look there for any deep appreciation of the events of those stormy times as for state papers or notes of diplomatic conferences. But it abounds in vivid portraits of the men and manners of the day. It paints rudely, yet to the life, the Paris of the Fronde, with all its effervescence and depression, its versatility and fickleness, its cowardice and its courage.

Mercur
Galant,
afterwards
Mercur de
France.

Of the *Mercur Galant*, established by Donneau de Visé in 1672, it may be said that it sought to combine the qualities of the *Gazettes*, both grave and gay. Like the former, it contained the state news and court circulars of the day. Like the latter, it amused its readers with satirical verses, and with sketches of men and manners, which, if not always true, were at least well invented. Reviews and sermons, law pleas and street airs, the last reception at the academy, and the last new fashion of the milliners, all find their place; nor can it be denied that the writer has redeemed the pledge implied in these words of his prospectus:—"If my letters" (for, like Loret, he cast his news into the epistolary mould) "be preserved, . . . they may hereafter become useful memorials, in which will be found many things not elsewhere to be met with." De Visé carried on his enterprise during more than thirty years, and at his death it was continued by that Rivière du Fresny, who has his little niche in Voltaire's portrait gallery:—

"Et Du Fresny, plus sage et moins dissipateur,
Ne fût pas mort de faim,—digne mort d'un auteur."

The successor of this worthy, Lefevre de Fontenay, altered the title to *Mercur de France* (a designation retained, with some slight modification, until 1853). The *Mercur* passed through many other hands before it came into those of Panckoucke, at the eve of the Revolution. Amongst its more conspicuous writers, immediately before this change, had been Raynal and Marmontel. The latter, indeed, had for many years been its principal editor, and in his *Memoirs* has left us a very interesting record of the views and aims which governed him in the performance of an arduous task. And he there narrates the curious fact, that it was Madame de Pompadour who invented the plan of giving pensions to eminent men of letters out of the profits of the *Mercur*. To one of Marmontel's predecessors the "privilege," or patent, had been worth more than L.1000 sterling annually. This revenue was now to be shared amongst several, and to become a means of extending royal "patronage" of literature at a cheap rate. Marmontel's account of his conversation

with Pompadour as to the selection of the patronized, is not the least amusing thing in those admirable *Memoirs*.

News-
papers.

It is, too, to this pension-scheme that we owe the *Contes Moraux*. Marmontel, who had long before lost his "patent" by an act of high-minded generosity, continued to share in the composition of the literary articles with Chamfort and La Harpe, whilst Mallet du Pan became the most prominent of its political writers. In 1789 the latter published a series of remarkable articles on the well-known book of De Lolme. In the same year he penned some comments on the "Declaration of the Rights of Man," very distasteful to violent men of all parties, but which forcibly illustrate the pregnant truth they begin with:—"The Gospel has given the simplest, the shortest, and the most comprehensive 'Declaration of the Rights of Man,' in saying, *Do unto others as you would that they should do unto you*. All politics hinge upon this."

In 1790 the sale of the *Mercur* rose very rapidly. It attained for a time a circulation of 13,000 copies. Mirabeau styled it in debate, "the most able of the newspapers." Great pains were taken for the collection of statistics and state papers, the absence of which from the French newspaper press had theretofore helped to depress its credit, as compared with the political journalism of England, and even of Germany. But in proportion as the Revolution marched on with more rapid strides towards an unchecked democracy, Mallet Du Pan evinced more and more unmistakably his rooted attachment to a constitutional monarchy. And, like so many of his compatriots, he soon found the tide too strong for him. The political part of the *Mercur* changed hands, and after the 10th August 1792 its publication was suspended.

The Mer-
cure dur-
ing the
Revolu-
tion.

All this time the *Moniteur* (*Gazette Nationale, ou le Moniteur Universel*) was under the same general management as the *Mercur Français* (so the title had been altered in 1791). The first idea, indeed, of this famous official journal appears to have been Panckoucke's, but it did not firmly establish itself until he had purchased the *Journal de l'Assemblée Nationale*, and so secured the best report of the debates. The *Moniteur*, however, kept step with the majority of the assembly, the *Mercur* with the minority. So marked a contrast between two journals, with one proprietor, gave too favourable a leverage to the republican wits not to be turned to good account. Camille Desmoulins depicted him as Janus,—one face radiant at the blessings of liberty, the other plunged in grief for the epoch that was rapidly disappearing. "When M. Panckoucke," he said, "leaves the printing-office of his *Moniteur Universel*, he is an ardent patriot; when he enters the editor's room of his *Mercur de France*, a sudden change comes over him, converting the patriot of the instant before into a furious aristocrat."

Contrast
between
the opin-
ions of Pan-
ckoucke's
Mercur
and those
of his Mo-
niteur.

When resumed, after a very brief interval, the *Mercur Français* became again *Mercur de France*; its political importance diminished, whilst its literary worth was enhanced. During the later days of the Revolution, and under the imperial domination, its roll of contributors included the names of Geoffroy, Ginguené, Morellet, Lacretelle, Fontanes, and Chateaubriand. The statesman last named brought upon the *Mercur* another temporary suppression in 1807, by words which were in true unison with the noblest deed of his chequered career,—that retirement, namely, from the imperial service which he resolved and effected on the day that the news of the execution of the Duke of Enghien reached him, being the day after he had been appointed by Napoleon a minister plenipotentiary. A few of these weighty words must find room. What may seem pedantic in their style is, it will be remembered, the local colouring of the time.

Suppres-
sion of the
Mercur
for an ar-
ticle by
Chateau-
briand.

... "When in the silence of despair no sound makes itself heard, save the chain of the slave and the voice of the informer,—when all tremble before the tyrant, and it becomes as dangerous to obtain his favour as to incur his displeasure, then arises the historian

News-
papers.

who embodies the vengeance of the nations. It is in vain that Nero prospers. Tacitus is already born within the bounds of the empire. Beside the ashes of Germanicus, he grows up to man's estate, unknown and unnoticed; and already has a righteous Providence placed in the hands of an obscure child the fame of the master of the world. If the part which the historian is called to play upon the world's stage be a noble one, yet it is often dangerous; but he ministers at an altar which, like that of honour, although abandoned, claims its sacrifice; the god is not annihilated because the temple is deserted."

Thus it chanced that alike under the brilliant despotism of Napoleon, and under the capricious malversation of Louis XV., the management of the *Mercure* was revolutionized for protests which conferred honour upon the journal, no less than upon the individual writers who made them. Resumed by other hands, the *Mercure* continued to appear until January 1820, when it was again suspended. In the following year it re-appeared as *Le Mercure de France au dix-neuvième Siècle*, and in February 1853 it finally ceased. A complete set extends to no fewer than 1611 volumes.

Journal de
Paris.

The only other newspaper of a date anterior to the Revolution which needs to be noticed here, is the *Journal de Paris*, which was commenced on new year's-day of 1777. It had but a feeble infancy, yet lived, as ricketty children sometimes do, for half a century. Its early volumes appear so insipid to a nineteenth century reader, that he wonders what can have been the cause of its occasional bickerings with the police. Its tameness, however, did not save it from sharing in the "suspensions" of its predecessors. After the Revolution, such men as Garat, Condorcet, and Regnaud de St Jean d'Angély appear amongst its contributors, but those of earlier date were intensely obscure. Its period of highest prosperity may be dated about 1792, when its circulation is said to have exceeded 20,000.

The Nou-
velles à la
Main.

The police adventures of the writers of the MS. News Letters, or *Nouvelles à la Main*, were still more numerous; and if we may judge from the copious specimens of these epistles which yet survive, must also not unfrequently have arisen from lack of official employment, rather than from substantial provocation. Madame Doublet de Persan, the widow of a member of the French Board of Trade, was a conspicuous purveyor of news of this sort. For nearly forty years, daily meetings were held in her house, at which the gossip and table-talk of the town were systematically (and literally) registered; and weekly abstracts or epitomes were sent into the country by post. Piron ("Piron qui ne fût rien, pas même académicien"), Mirabaud, Falconet, D'Argental (the "ame damnée" of Voltaire, as Marmontel called him), and, above all, Bachaumont, were prominent members of the "society," and each of them is said to have had his assigned seat beneath his own portrait. The lady's valet de chambre appears to have been editor *ex officio*; and as he occasionally suffered imprisonment, when offensive news-letters had been seized by the police, so responsible a duty was doubtless "considered in the wages." News and anecdotes of all kinds,—political and literary, grave, gay, or merely scandalous,—were all admitted into the *Nouvelles à la Main*; and their contents, during a long series of years, form the staple of those *Mémoires Secrets pour servir à l'Histoire de la République des Lettres*, which extend to 36 volumes, have been frequently printed (at first with the false imprint,—Londres: John Adamson, 1777–89), and are usually referred to by French writers as the *Mémoires de Bachaumont*.

The news-
papers of
the Revolution.

The journalism of the first Revolution has been the theme of many bulky volumes, and their number is still on the increase. Like all modern insurrections, in which legitimate and long repressed aspirations have been commingled with visionary but fondly-cherished dreams of a world wherein luxury should precede labour, and vice imperceptibly transmute itself into virtue; the period of the Revolution was marvellously fertile in every kind of intellectual

News-
papers.

effort. The simple recital of the mere titles of the newspapers which then appeared throughout France fills more than forty pages of larger dimensions than those which the reader has now before him. It is obvious, therefore, that a very casual glance at this part of our subject is all that can here be given to it.

When at least one half of the French people was in a ferment of hope or of fear at the approaching convocation of the States-General, most of the existing newspapers were still in a state of torpor. Long paragraphs, for example, about a terrible "wild beast of the Gevaudan"—whether wolf or bear, or as yet nondescript, was uncertain—were still current in the Paris journals at this momentous juncture; just as the "enormous gooseberry" fills up, at the dull season of the year, a blank in an English, or the "marvellous sea-serpent" a blank in an American, country paper. Mirabeau was amongst the foremost to supply the popular want. His *Lettres à ses Commettants* began on the 2d May 1789, and with the twenty-first number became the *Courrier de Provence*. Within a week Marat (afterwards Duke of Bassano) followed with the *Bulletin des Séances de l'Assemblée Nationale*, and Lehoudey with the *Journal des États Généraux*. In June, Brissot de Warville began his *Patriote Français*. Gorsas published the first number of his *Courrier de Versailles* in the following month, from which also dates the famous periodical of Prudhomme, Loustalot, and Tournon, entitled *Révolutions de Paris*, with its characteristic motto,—“Les grands ne nous paraissent grands, que parce que nous sommes à genoux; levons nous!” A month later, Barère and Loubet began the *Journal des Débats*, and Marat the *Ami du Peuple* (which at first was called *Le Publiciste Parisien*). The *Moniteur Universel* (of which we have spoken already), was first published on the 24th November, although numbers were afterwards printed bearing date from the 5th May, the day, it will be remembered, on which the States-General first assembled. Camille Desmoulins also commenced his *Révolutions de France et de Brabant* in November 1789. The *Ami du Roi* was first published in June 1790; *La Quotidienne* in September 1792.

Of all these prominent journals the *Moniteur* and the *Débats* alone have survived until now. A few of them lasted until 1794 or 1795; one continued until recently; but most of them expired either in the autumn of 1792, or with the fall of the party of the Gironde in September 1793. In some of these papers the energy for good and for evil of a whole lifetime seems to be compressed into the fugitive writings of a few months. Even the satirical journals which combated the Revolution with shafts of ridicule and wit, keen enough after their kind, but too light to do much damage to men who were terribly in earnest, abound with matter well deserving the attention of all students desirous of a thorough knowledge of the period. Of this class those more especially in which Peltier was concerned—as, for example, the *Actes des Apôtres*, the *Paris*, and *L'Ambigu*—depict the Royalists themselves vividly enough, whatever may be the amount of credit due to their delineations of their foes. Peltier's name is now best remembered for the famous trial which his incessant attacks upon Napoleon entailed on him. His fondness for drawing comparisons between the "yellow emperor" and the "black emperor," greatly to the advantage of the Haytian, so pleased the latter as to bring him very substantial and acceptable marks of gratitude, in the shape of numerous bags of coffee and hogsheads of sugar, which were speedily converted into cash for the gratification of tastes little in harmony with the ordinary resources of an exiled journalist. The sad contrast between the gratitude of the negro monarch and the indifference of the government of the Restoration towards services which had been long and faithful, prompted an epigram, which unfortunately alienated his distant benefactor:—

The light
skirmish-
ers of the
revolution-
ary press.

News-
papers.

"Mon roi me traite comme un nègre,
Mais mon nègre, à son tour, me traite comme un roi."

So that the poor author died, if we accept the dictum of Voltaire, an appropriate death, in a garret, in the spring of 1825.

The consular government began its dealings with the press by reducing the number of political papers to thirteen. At this period the original number of daily journals had been nineteen, and their aggregate provincial circulation, apart from the Paris sale, 49,313, or 2600 each, on the average.

The Jour-
nal des
Débats.

Under Napoleon, the *Moniteur* was the only political paper that was really regarded with an eye of favour. Even as respects the nation at large, the monstrous excesses into which the revolutionary press had plunged left an enduring stigma on the class. When M. Bertin acquired the *Journal des Débats* from Baudouin, the printer, for 20,000 francs, he had to vanquish popular indifference on the one hand, as well as imperial mistrust on the other. The men he called to his aid were Geoffroy and Fievée; and by the brilliancy of their talents, and the keenness of his own judgment, he converted the *Débats* into a paper having 32,000 subscribers, and producing a profit of 200,000 francs a year. When a special censorship was about to be imposed on it, in 1805, at the instance of Fouché, a remarkable correspondence took place between Fievée and Napoleon himself, in the course of which the emperor wrote, that the only means of preventing a newspaper from suspension was "to avoid the publication of any news unfavourable to the government, until the truth of it is so well established that the publication becomes needless, the bad news being in everybody's mouth." ("Toutes les fois qu'il parviendra une nouvelle défavorable au gouvernement, elle ne doit être publiée, jusqu'à ce qu'on soit tellement sûr de la vérité qu'on ne doive plus la dire, parce qu'elle est connue de tout le monde.") The censorship was avoided, but Fievée had to become the responsible editor, and the title was altered to *Journal de l'Empire*—the imperial critic taking exception to the word *Débats* as "inconvenient." The old title was resumed in August 1815. The revolution of July did but enhance the power and the profit of the paper. It has held its course with dignity as well as ability amidst recent perils, and may still be said, in the words which Lamartine applied to it in an earlier day, to have "made itself part of French history."

Shortly before the *Journal de l'Empire* became again the *Journal des Débats* (in 1815), a severance occurred amidst both the writers and subscribers, which led to the foundation of the *Constitutionnel*, which for a short time bore the title of *L'Indépendant*. The former became, for a time, the organ of the Royalists, *par excellence*, and furnished its due quota of "ogre de Corse" and the like; the latter, the leader of the opposition. In 1824, however, both were in conflict with the government of the day. At that date the statistics of the Paris press were thus stated, in a secret report addressed to the ministry:—

Statistics
of the
Paris press
in 1824.

Government Press.		Opposition Press.	
Name of Paper.	Circulation.	Name of Paper.	Circulation.
1. Journal de Paris.	4,175	1. Le Constitutionnel.	16,250
2. L'Etoile	2,749	2. Journal des Débats.	13,000
3. Gazette de France	2,370	3. La Quotidienne.....	5,800
4. Le Moniteur.....	2,250	4. Le Courier Français	2,975
5. Le Drapeau } Blanc	1,900	5. Journal de Com- } merce	2,380
6. Le Pilote	900	6. L'Aristarque	925
Total	14,344	Total	41,330

The rapid rise of the *Constitutionnel* was due partly to the great ability and influence of Étienne, of Beranger, and

of Saint Albin (who had been secretary to Carnot, in his ministry of 1815), all of whom co-operated in its early editorship; and partly to its sympathy with the popular reverence for the memory of Napoleon, as well as to the vigorous share it took in the famous literary quarrel between the Classicists and Romanticists (although in that quarrel it took what may now be called the side of the vanquished). Its part in bringing about the revolution of 1830 raised it to the zenith of its fortunes. For a brief period it could boast of 23,000 subscribers, at 80 francs a year. But the invasion of cheap newspapers, and that temporary lack of enterprise which so often follows a brilliant success, lowered it with still greater rapidity. When the notorious author of the *Mémoires d'un Bourgeois*, Dr Véron, purchased it, the sale had sunk to 3000. Véron gave 100,000 francs for the wretched *Juif Errant* of Sue, and the Sue fever rewarded him for a while with more than the old circulation. Recently it has been under the editorship of Césena, Granier de Cassagnac, and La Guéronnière; and it need scarcely be added that its glory has departed.

The cheap journalism of Paris began in 1836 (1st July), with the famous journal of M. De Girardin, *La Presse*, followed instantly by *Le Siècle*, under the management of M. Dutacq. The first-named journal attained a circulation of 10,000 copies within three months of its commencement, and soon doubled that number. The *Siècle* prospered even more strikingly, and in a few years had reached a circulation (theretofore without precedent in France) of 38,000 copies.

The rapid rise of the newspaper press of Paris will be best appreciated, if we tabularize the number of stamps issued,—as has been already done for the British newspapers:—

Years.	No. of Stamps.
1828.....	28,000,000
1836.....	42,000,000
1843.....	61,000,000
1844.....	62,283,200
1845.....	65,000,000
1846.....	79,000,000

At the date last mentioned the relative position of the twenty-six daily papers stood thus:—

Name of Paper.	Circulation.	Name of Paper.	Circulation.
*Le Siècle.....	31,000.	Moniteur Parisien.....	Betwn. 2000 and 3000
*La Presse.....	Between 20,000	La Réforme.....	
*Le Constitutionnel.	& 25,000.	L'Echo Français.....	
*Journal des Débats	Between 10,000	Courier Français.....	
L'Époque.....	& 15,000.	Democratie Pacifique...	
Le National.....	Between 3000 and 5000.	Le Droit.....	3000
*Le Charivari.....		*Gazette des Tribunaux	
*Gazette de France..		L'Entr'acte.....	Betw. 500 and 2000
Le Commerce.....		Journal de Paris.....	
La Quotidienne.....		Le Messager.....	
*La Patrie.....		Le Corsaire-Satan.....	
*L'Estafette.....		La France.....	
L'Esprit Public.....			
*L'Univers.....			

The *Moniteur* does not here appear, for the reason that the greater part of its circulation is official and gratuitous. It is just to add, that the vast disparity of circulation shown by this table (as for example, between journals like *Le National* and *Le Siècle*), affords no test whatever of public opinion, either as to their politics, or their ability. The business was simply an affair of story-telling. The most Rise of the trashy novelist, who had for a moment won the public ear, feuilleton. was able (for his brief period) to dictate terms to the shrewdest and most experienced proprietor of a newspaper. Thus it was that M. Dumas was enabled to make a contract with the proprietors of *La Presse* and *Le Constitutionnel* jointly, which brought him in 64,000 francs a year; and then to sell the right of reprinting his tales, for

News-
papers.

a round sum, to a certain M. Troupenas, who, according to the Paris wits, killed himself by a brain fever, brought on in a vain attempt to divide M. Dumas' lines into half lines, in order to increase the number of volumes.¹

Newspa-
per flood of
1848.

To a great extent, the inundation of newspapers which followed the revolution of February 1848, was but a parody—and a very poor one—on the revolutionary press of 1793. Most of them, of course, had very short lives. When Cavaignac took the helm he suppressed eleven journals, including *La Presse* and *L'Assemblée Nationale*. The former had at this period a circulation of nearly 70,000, and its proprietor, in a petition to the National Assembly, declared that it gave subsistence to more than 1000 persons, and was worth in the market at least 1,500,000 francs. In August, the system of sureties was restored. On the 13th June 1849 the present Emperor, as "President of the Republic," suspended *Le Peuple*, *La Révolution Démocratique et Sociale*, *La Vraie République*, *La Démocratie Pacifique*, *La Réforme*, and *La Tribune des Peuples*. On the 16th July 1850 the Assembly passed what is called the "Loi Tingué," by which the author of every newspaper article on any subject, political, philosophical, or religious, was bound to affix his name to it, on penalty of a fine of 500 francs for the first offence, and of 1000 francs for its repetition. Every false or feigned signature was to be punished by a fine of 1000 francs, "together with six months' imprisonment, both for the author and the editor." The practical working of this law lies in the creation of a new functionary in the more important newspaper offices, who is called "secrétaire de la rédaction," and is, in fact, the scape-goat *ex officio*. In February 1852 all the press laws were incorporated, with increased stringency, into a "Décret organique sur la presse." The stamp duty for each sheet was fixed at six centimes, within certain dimensions, and a proportional increase in case of excess. By this law the newspapers are at present governed; and their price—*La Presse* only excepted—has returned to the tariff of 1835. The existing number of daily papers in Paris is but fourteen (the *Moniteur* included), and is made up of those to which an asterisk is prefixed in the preceding table, with the addition of *L'Assemblée Nationale*, *Le Pays*, *L'Union*, and the *Journal des Faits*. The relative circulation of the six leading papers recently stood thus:—(1.) *Siècle*; (2.) *Presse*; (3.) *Constitutionnel*; (4.) *Patrie*; (5.) *Débats*; (6.) *Assemblée Nationale*. The number of provincial papers exceeds 500, but scarcely ten of them possess importance of any kind.

IV.—NEWSPAPERS OF GERMANY AND OF NORTHERN EUROPE.

Early
German
papers.

No real serial newspaper can be shown to have existed in Germany of earlier date than 1615, when Egenolph

¹ The following is a literal and *lineal* specimen of the dialogue of *Les Trois Mousquetaires*, as published in *Le Siècle*:—

"Mousq.—'Eh bien?'
Valel.—'Rien.'
M.—'Rien?'
V.—'Rien.'
M.—'Comment?'
V.—'Rien, vous dis-je.'
M.—'C'est impossible,' &c.

Emmel, a bookseller of Frankfort, established one, of which little more is now known, than that in the following year his example was imitated, doubtless with some improvement, by the foundation of the *Frankfurter Oberpostamtszeitung*. Fulda appears to have been the next German town to possess a newspaper; then Hildesheim (1619), and Herford (1630). In the course of the century almost all German cities of the first rank possessed their respective journals. The earliest in Leipsic bears date in 1660. The *Hamburgischer Correspondent* dates from 1714, and was almost the only German newspaper which really drew its foreign news from "our own correspondent." Berlin had two papers, those of Voss and of Spener, both of which are still published. They possessed in their earlier career some literary value, but were politically null. Some half-dozen papers which glimmered in the surrounding darkness were the reservoirs whence the rest replenished their little lamps. On the whole, it may be said that the German newspapers were of very small account, until after the outbreak of the French Revolution. Nor, indeed, can any journal of a high order be mentioned of prior appearance to the *Allgemeine Zeitung*, founded by Cotta (at first under the title of the *Neueste Weltkunde*) in 1798, and which is still at the head of the political press of Germany. Posselt was its first editor, but his want of nerve—perhaps of physical health—hindered the application of his high powers to political journalism; and to this constitutional impediment another was added, which is very honourable to his memory. His articles gave offence to the Austrian court, and the paper had to change both its title and its place of publication. It had been commenced at Tübingen, and removed to Stuttgart. It was now transferred to Ulm, and again from thence to Augsburg. It was Cotta's aim to make this the organ of statesmen and publicists, to reach the public through the thinkers, to hold an even balance between the rival parties of the day, and to provide a trustworthy magazine of materials for the historians to come; and, in the course of time, his plan was so worked out as to raise the *Allgemeine Zeitung* into European fame. L. F. Huber succeeded Posselt in the editorship. He was of a family which had already distinguished itself in that kind of literary enterprise which more especially aims at familiarizing to the minds of one country the great works and the prevailing thought of other countries. He died whilst yet in the prime of life, but not before he had rendered good service. Stegmann, Kolb, Mebold, and Altenhöfer have successively been the chief editors since Huber's death. Cotta was also the founder, at various periods, of the *Morgenblatt*, which became famous for its critical ability and tact; of *Vesperus*; of *Das Inland*; of *Nemesis*; of the *Oppositionsblatt* of Weimar (for a time edited by Bertuch); and even of the *Archives Parisiennes*. His ventures were not, of course, uniformly successful in this or in any other of the many spheres of his activity, but it is rare that men of like enterprise have made so few failures. Whilst French influence was dominant in Germany, the German papers were naturally enough little more than echoes of the Parisian press. But amidst the excitements of the "war of liberation" a crowd of new journals appeared. Niebuhr began a *Preussische Correspondent*; Görres undertook the *Rheinische Mercur*; by the war Wetzel, somewhat later, the *Frankische Mercur*, published at Bamberg; Friedrich Seybold the *Neckarzeitung*. Some of these journals lasted but two or three years. Most of the survivors fell victims to that resolution of the Diet (20th September 1819) which subjected the newspaper press, even of countries where the censorship had been formally abolished, to police superintendence of a very stringent kind.

The aspirations for some measure of freedom which burst forth again under the influences of 1830 led to the establishment of such papers as Siebenpfeiffer's *Westbote*; Loh-

News-papers.

Crusade of the Diet against the German press.

The German press subsequently to 1840.

Statistics of the German press in 1849.

bauer's *Hochwächter*; Wirth's *Deutsche Tribune*; Eisenmann's *Baierische Volksblatt*; *Der Freisinnige* of Rotteck and Welcker; and many more of much freer utterance than had theretofore been heard in Germany. This led, in the ordinary course, to new declarations in the Diet against the license and revolutionary tendencies of the press, and to "regulations" of a kind which will be sufficiently indicated by the mention of one, in virtue whereof no editor of a suppressed journal could undertake another journal, during the space of five years, within any part of Germany. It need hardly be added that few of the newspapers of 1830 saw the Christmas of 1832. Very gradually, after 1840, some of the older journals—and amongst the number the patriarch of all, the *Frankfurter Oberpostamtzeitung*—plucked up courage enough to speak out a little; and some additional newspapers were again attempted. Amongst those which acquired deserved influence were Brockhaus' *Deutsche Allgemeine Zeitung*, the advocate of free trade and of a moderate liberalism, and possessing a large circulation in Northern Germany; the *Deutsche Zeitung*, edited by Gervinus, at Heidelberg (July 1847); and the *Dorfzeitung*, published at Hildburghausen. The stirring events of 1848 called forth in Germany, as in so many other countries, a plentiful crop of political instructors of the people, many of whom manifestly lacked even the capacity to learn, and vanished almost as suddenly as they had appeared. But it is undeniable that a marked improvement in the ability and energy of the German political press may be dated from this period, and bids fair to continue, despite all impediments.

In 1833 the number of German newspapers of all kinds, popular journals (*Volksblätter*) included, but without reckoning periodicals devoted to literature or science, had amounted to but 335, or thereabout; in 1849 this number had increased to 1551, and their geographical distribution was as follows:—

States.	No. of Papers.	States.	No. of Papers.
1. Anhalt.....	10	16. Lübeck.....	4
2. Austria.....	74	17. Luxemburg.....	4
3. Baden.....	55	18. Mecklenburg.....	22
4. Bavaria.....	127	19. Nassau.....	13
5. Bremen.....	18	20. Oldenburg.....	8
6. Brunswick.....	9	21. Prussia.....	632
7. Frankfort.....	17	22. Reuss.....	11
8. Hamburg.....	24	23. Saxony.....	183
9. Hanover.....	32	24. Saxon Duchies.....	44
10. Hesse-Cassel.....	22	25. Schaumburg-Lippe.....	2
11. Hesse-Darmstadt.....	34	26. Schleswig.....	5
12. Hesse-Homburg.....	4	27. Schwartzburg.....	12
13. Hohenzollern.....	4	28. Waldeck.....	2
14. Holstein.....	17	29. Wurtemberg.....	67
15. Lippe-Detmold.....	4		

In addition to these, but included in our total of 1551, 77 German newspapers were published in the Swiss cantons, and 14 in the Baltic provinces of Russia. Many of those reckoned in this enumeration have ceased to appear, but others have taken their places; and the total number in 1855 was estimated to be a little above 1600.

The newspaper press in the Austrian dominions.

At the beginning of 1840 the whole number of Austro-German and Austro-Hungarian periodicals, of all sorts, was under 100; of which but 22 were (after a fashion) political newspapers; and of these nearly all drew their materials and their inspiration from the official papers of Vienna (*Wiener Zeitung* and *Oestreichischer Beobachter*). These two were all that appeared in the capital. Agram, Pesth, Presburg, Limburg, and Prague had each two. No other city had more than a single journal, and that one a nullity, in the sense in which newspapers were regarded in France, and are still regarded in Britain or America. In 1846 the aggregate number of periodicals had grown to 155, of which 46 were political, but poli-

tical only in the character of mere conduit-pipes for intelligence "approved of" by the government. What sort of journalists were likely to grow up in these Viennese leading-strings may be easily imagined. But it would have been impossible to have conceived beforehand the ludicrous exhibition of their talents which these writers made, when the short-lived freedom of the press burst upon them like a thunder-cloud in March 1848. Yet here, too, as elsewhere, some good seed was cast into the ground, which no busy enemy has been able quite to root up, and which has already produced the earnest of a harvest to come. In 1855 the number of political papers published throughout the entire territory, at present under Austrian government, the Italian provinces excepted, was 57. Their distribution and languages were respectively as follows:—

* In addition to one in Italian.

* In addition to one in Italian.

In 1856 the leading papers of Vienna,—namely, the *Ost Deutsche Post*, the *Österreichische Zeitung*, and the *Wanderer*,—were in a thriving state. The imposition in the autumn of 1857 of a heavy stamp duty on Austrian newspapers, together with an additional 50 per cent. on the tax upon advertisements, coming, too, as they have come, at a time of commercial difficulty, will destroy this prosperity, and will be another blow at the progress of opinion and free aspiration. But it is a step thoroughly Austrian, and will, when the end arrives, be found to have had its due reward.

In Prussia the influence of the events of 1848 upon the newspaper press was naturally much greater, and it has been also more enduring, than in most other parts of Germany. There the ground was to a great extent prepared for freer discussion, and the men who undertook it were better fitted for their work. But even here the contrast between the present reality and the past anticipation is not enlivening. There is much activity; little independence. The journals which enjoy the widest circulation are distinguished by literary merit and political servility. The *Berliner Privilegierte Zeitung* had 12,200 subscribers in 1855; the *Berlinischen Nachrichten*, 7600; the notorious *Kreuzzeitung*, the organ of the re-actionists (founded on the 1st July 1848), has 5000; the *Zeit*, 6600; the *National Zeitung*, 5400. Of the provincial press, the *Kölnische Zeitung* is foremost; next to it come the Gazettes of Königsberg, Aix-la-Chapelle, and Breslau.

News-
papers.
The news-
papers of
Sweden.

In Sweden the earliest regular newspaper appears to have been the *Ordinarie Post-Tidende*, first published in 1643, and continued until 1680, which was followed by the *Svensk Mercurius* (1675-1683), and the *Relationes Curiosæ* (in Latin, like their titles) which began in 1682, and ceased in 1701. In 1742 a Swedish newspaper in French (*Gazette Française de Stockholm*) was commenced, and was followed, in 1772, by the *Mercure de Suède*. But the press in Sweden had small political influence until so recent a date as 1820, when the *Argus* was established by Johannsen. The strife between "Classicists" and "Romanticists" spread itself in Sweden, as in France, from the field of literature into that of politics. Crusenstolpe's *Fäderneslandet*, and Hjerta's *Aftonbladet*, were long the most conspicuous of the Swedish journals; the former on the side of the royalists, the latter on that of the reformers. Hjerta's paper, in its best day, could boast of a circulation of 5000 copies; but on the accession of King Oscar it ceased to appear as an opposition organ. The official paper is *Post och Inrikes Tidningar*, the original title of which was *Sveriges Statstidning*. Almost every town in the provinces has its paper. The growth of the Swedish press during the present century may be thus epitomized:—

Year.	No. of Papers.	Year.	No. of Papers.	Year.	No. of Papers.
1801.....	25	1829.....	62	1841.....	112
1821.....	48	1831.....	80	1850.....	113

Newspa-
pers of
Denmark,

If in Sweden the political influence of the press is a novelty, in Denmark it is a newer thing still. Until 1830 Copenhagen had but two papers, and they filled their columns with mild extracts from foreign journals. Real activity in this direction dates but from the establishment of the Provincial States in 1834. The oldest existing paper is the *Berlingske Tidende*, which dates from 1749, and was at first published in German. It is now a semi-ministerial journal. The *Fädrelandet* belongs to the opposition, and in 1848-9 was in a glow of zeal for Scandinavianism and "Young Denmark." The total number of political journals existing in 1849 was 36. Those belonging to the provinces are of small account. The oldest Norwegian paper is the *Christiania Intelligentsedler*, founded in 1763. Next to this comes the *Adressecontoirs Efterretninger*, published at Bergen. *Den Constitutionelle* is the organ of the government, and has absorbed (for in newspaper affairs incorporation almost always means absorption) an older paper, called *Norske Rigstidende*. The *Morgenblad* is the journal of the popular party, and dates from 1819.

V.—NEWSPAPERS OF HOLLAND AND BELGIUM.

Nieuwe
Tydinghen,
published
at Antwerp
in 1605.

In respect of the first publication of a newspaper, Belgium takes rank before France, Germany, and Britain. The *Nieuwe Tydinghen* of Antwerp, published by Abraham Verhoeven, dates from 1605, as appears by the privilege accorded to him for the exclusive retailing of news by the Archdukes Albert and Isabella. But as no copy of any number of this paper anterior to 1619 is now known to exist, the statement must stand open to correction upon a point which is at present doubtful,—the fact, namely, whether or not this "Tydinghe" was from its origin a regular periodical. M. de Jonghe possesses portions of it from 1619 to 1630. It seems probable that the *Gazette Extraordinaris Posttydinghen*, published by Wilhem Verdussen between 1637 and 1644, is a continuation of Verhoeven's

paper. But be this as it may, that of Verdussen was certainly the foundation of the well-known *Gazette van Antwerpen*, which continued to appear until 1827.

Bruges had also its *Nieuwe Tydinghen uyt verscheijde gemesten*, published (in black letter) *Te Brugghe, by Nicholas Breyghel, in de Philips-Stoc-Straete aen S. Donaes*. When this paper was commenced is uncertain, but various numbers of it exist with dates ranging between 1637 and 1645. In one of these (26th July 1644) a *Brusselsche Gazette* of the 24th of that month is quoted, but for which citation, no Brussels paper is known of earlier date than 1649. When the first number of *Le Courrier véritable des Pays-Bas* made its appearance, the publisher (Jean Mommaert) prefaces the first number by an address to the reader, in which he says:—"I have long endeavoured to meet with somebody who would give employment to my presses in defending truth against the falsehoods which malignity and ignorance send daily abroad. I have at length found what I sought, and shall now be able to tell you weekly the most important things that are going on in the world." This paper became afterwards the *Gazette de Bruxelles*, then *Gazette des Pays-Bas*; and, under the last-named title, it continued to appear until 1791. The *Annales Politiques* of Linguet was one of the most remarkable of the political journals of Brussels in the last century. For a time the editor won the favour of the Emperor Joseph II. by praising his reforms, and the government subscribed for 1200 copies of his paper at two louis d'ors each a year; but here, as in almost every other place of residence during his chequered career, Linguet at length incurred fine and imprisonment. His journal was at one time so popular that a printer in Brussels itself regularly and rapidly published a pirated edition of it. When the editor exposed the fraud in very severe terms, the pirate faithfully copied the censure without a word of comment. *Le National* was a famous paper for a short period prior to the revolution of 1830. Soon after its cessation [its presses were destroyed by the populace on the 26th August] the official journal, *Moniteur Belge*, was established—"the ministry deeming it indispensable, to the success of its great political enterprise, that a journal should be created which might expound its views, and act daily upon public opinion;" and, on decree of the regency, it was published accordingly.

The first newspaper published at Ghent, *Gazette van Gend*, Dutch appeared in 1667. *Den Vaderlander*, begun in October 1829, is one of the most widely-circulated of the Flemish newspapers. Holland has always been rich in newspapers, but they have usually had more weight commercially than politically. Those in most esteem are the *Allgemeene Handelsblad* of Amsterdam; the *Harlemsche Courant*; and the *Staats Courant*, and *Journal de la Haye*, both of which are printed at the Hague.

(Warzée, *Essai Historique et Critique sur les Journaux Belges*, Gand, 1845, passim; *Allgem. Deutsche-Real Encyclopädie*, ut supra; Kolb, art. "Linguet" in *Biographie Universelle*.)

VI.—NEWSPAPERS OF ITALY AND OF THE PENINSULA.

Of the manuscript gazettes or "notizie scritte" of Venice, little need here be said. They are memorable as indications of the Venetian policy, and also as having probably given us (from the small coin for which they might be read at certain public places) our word "gazette;" but, like their congeners in England and in Germany, were not newspapers. The often-quoted bull of Pope Gregory XIII. was aimed rather at the writers than at the printers of news, and when these narratives or "relations" were at length printed, they were occasional, not periodical. Nor can it, we believe, be fixed with any certainty at what date or in what part of the country an Italian serial newspaper was

first printed. In recent times Italy has had many admirable scientific and literary magazines, but political journalism has scarcely taken root in that soil. The *Diario di Roma*, the *Gazzetta di Napoli*, and many similar papers published "with approbation" in Lucca, Bologna, Milan, and Florence, have never possessed much influence either for good or evil.

Newspaper
press of
Sardinia.

In later days, however, Sardinia has formed a notable exception to this state of things. No fewer than 45 purely political papers were published in the Sardinian dominions in 1852, and of these 41 were in Italian and 4 in French. The leading journal was the *Parlamento*, which, in 1855, altered its name to *Piemonte*. The *Opinione* represents the party of progressive reform; the *Armonia* the clerical party. The popular paper, entitled *Gazzetta del Popolo*, had, at the last-named date, about 7000 subscribers. Of the vast crowd of journals of a popular kind, many of them marked by ability, but nearly all of necessity still more remarkable for extravagance, which rushed forth so tumultuously in many parts of Italy in 1847 and 1848, few survived the re-action and the repressive atrocities of 1849.

Spanish
journalism.

In Spain no newspaper of any kind existed earlier than the last century. Even within half a century of the present year, its capital contented itself with a single journal, the *Diario de Madrid*. The peninsular war, and the establishment of the Cortes, gave the first impulse towards something which might be called political journalism, but the change from total repression to absolute freedom was too sudden not to be grossly abused. The *Diario de los Cortes*, the *Semanario Patriótico* (published at Cadiz from 1808 to 1811), and the *Aurora Mallarquina* (published at Palma in 1812-13), are the first of the new papers that attained importance. Most of them fell with the Cortes in 1823. In the following year Ferdinand decreed the suppression of all the journals except the *Diario* and the *Gaceta* of Madrid, the *Gaceta de Bayona*, and certain provincial papers which dealt exclusively with commercial or scientific subjects. At the close of his reign but three or four papers were published in Madrid. Ten years afterwards there were 40; but their number is far more noticeable than their value. Spanish newspapers have been too often the mere stepping-stones of political adventurers, and not unfrequently the worst of them appear to have served the turn more completely than the best. Gonzales Bravo attained office mainly by the help of a paper of notorious scurrility,—*El Guirigay*. The *Universal* and the *Correo* were successively the tools of José Salamanca. At the end of 1854 the number of political journals published in Madrid was about 40, and the most conspicuous of them were *España* and *El Clamor Público*. In Portugal the newspaper press is of still less account. The number of newspapers published in Lisbon in 1852 was 7; in Oporto, 5. The *Diario do Governo* is the official organ.

(*Allg. Deutsche Real-Encyclopädie*, ut supra, 456-460; Ford, *Handbook for Spain*, 3d edition, 666, 667; *British Quarterly Review*, vi., 315-332, art. "Newspaper Press of Spain.")

VII.—NEWSPAPERS OF INDIA, AND THE RESTRICTIONS IMPOSED ON THEM.

For a considerable period in the history of the government of India by the Company, the Indian press was very unimportant both in character and influence. It was permitted to shape its course and to gain a position as it could, under the potent checks of the deportation power and the libel law, without any direct censorship. Nor was it found difficult to inflict exemplary punishment on the writers of "offensive paragraphs."

Prior to Lord Wellesley's administration the most considerable newspapers published at Calcutta were *The World*, *The Bengal Journal*, *The Hurkaru*, *The Calcutta*

Gazette (the organ of the Bengal government), *The Telegraph*, *The Calcutta Courier*, *The Asiatic Mirror*, and *The Indian Gazette*. Mr Duane, the editor of the first-named paper, was sent to Europe in 1794 for "an inflammatory address to the army;" as was Mr Charles Maclean, four years afterwards, for animadverting in *The Telegraph* on the official conduct of a local magistrate.

Lord Wellesley was the first governor-general who created a censorship (April 1799). The circumstances of the time were critical: the war with Tippoo was at its height. In writing to Sir Alured Clarke, Lord Wellesley thus expressed himself:—"I cannot but suspect the existence of a systematic design of mischief among the editors of several papers, particularly *The Asiatic Mirror*, *The Telegraph*, and *The Post* . . . To-day I find in *The Post* . . . a plain suggestion to Tippoo of the advantages which he might derive by sending his looties into the Carnatic; and in *The Mirror* . . . you will find a dissertation on the causes, nature, and extent, of the conspiracy discovered in Bengal. . . . I request you will embark the editor of that paper (whom I understand to be a Mr Bruce, a desperate Jacobin) for Europe in the first ship which shall sail from Calcutta."

His lordship then proceeds to establish certain regulations for the future control of the press, and adds that he is determined, on his return to Bengal, to limit "the extravagant number of newspapers now published in Calcutta." Of the new press code, the most important section runs thus:—"1. No paper to be published at all until it shall have been inspected by the Secretary to government, or by some person authorized by him for the purpose." It is honourable to the memory of the noble marquis, that on maturer thought, when the passing excitements of the moment had given place to the judicial analysis of self-examination, and when policy had been tested by time, he indicated his changed views, and his desire that the decree of April 1799 should not be made a model, by striking out all the passages relating to the Calcutta newspapers from the revised *Dispatches*, which he was sending to the press.

According to Mr H. H. Wilson, the later historian of British India, "the duties of the censorship were leniently discharged;" and he inclines to think that "this control, and the improving tastes and feelings of the age, gave to the Indian chronicles a new character, and rendered them respectable, if not very authentic, vehicles of public information." But the Marquis of Hastings appears to have judged less favourably of their operation. He thought it more important to secure (to use his own words) "the salutary control which public scrutiny exercises over supreme authority, and the cheerfulness and zeal with which all ranks of society co-operate in measures the motives and objects of which they understand, and in which they concur." He therefore, in 1818, abolished the censorship. Whatever the "leniency" of its application may have been, the position of the newspaper press was unmistakeable. We find it significantly marked by Lord Wellesley himself, when he wrote in 1804 to the Danish governor of Serampore, in reply to a complaint against a Bengal journal,—"*The necessary orders have been communicated to the editors of the newspapers published in Calcutta, for the purpose of preventing the publication of any injurious reflections,*" &c.

The power of transporting obnoxious editors to Europe of course remained. Perhaps the most notorious of all instances of its exertion was that of the editor of *The Calcutta Journal*, the late Mr J. S. Buckingham, which occurred immediately after Lord Hastings' departure from India, and during the government of his temporary successor, Mr John Adam. What Lord Hastings had regarded as salutary Mr Adam stigmatized as highly pernicious. "The governor-general," he wrote, "protests against the assumption of this right of control over the government and

Licensing
laws of
1823.

its officers by a community constituted like the European society of India." The removal of Mr Buckingham was followed closely (14th March 1823) by a new licensing act, far exceeding in stringency that of Lord Wellesley, which had been cancelled five years before; and on the 5th of April 1823, by an elaborate "Regulation for Preventing the Establishment of Printing-Presses without License, and for Restraining, under certain circumstances, the Circulation of Printed Books and Papers." Of this document, it is enough to say, that it appears to have been framed with admirable fidelity on the Star-Chamber precedents of the sixteenth century. The first application of it was to the suppression of *The Calcutta Journal*.

Connection
of govern-
ment ser-
vants with
the press.

Under the Marquis of Hastings, the germ of a native press had ventured to show itself. Persian and Bengal papers had just started up, when the new laws nipped most of them in the bud. In some cases, however, natives succeeded in obtaining the necessary licenses for the establishment of others. Meanwhile a question grew into importance which had not been provided for,—the right, namely, of the Company's servants to connect themselves with the European press, whether as writers or as proprietors. On this subject Lord (then Sir C.) Metcalfe recorded a remarkable minute in December 1828. At this date the repressive laws of 1823 had been already in practice relaxed. Lord Metcalfe was strongly in favour of increased liberty. He desired that ample power should always be possessed by the local government for "protecting the safety of the state," but thought that "to crush what is in itself capable of great good, from an apprehension that it may possibly, under circumstances as yet unconceived, be converted into an evil, would be a forecast more honoured in the breach than in the observance;" and regretted "that the orders of the Court of Directors have not left employment in the press open to all their servants, except those in high official stations, . . . on the indispensable condition that such employment should not be allowed to interfere with the due discharge of public duties."

State of the
Indian
press in
1832.

In the course of the elaborate inquiry into the administration of the government of India, which occupied both Houses of Parliament in 1832, prior to the renewal of the Company's charter, the statistics of the Indian press were thus stated:—(1. European.) Three daily newspapers, *The Bengal Hurkaru*, *The John Bull*, *The Indian Gazette*; one bi-weekly, *The Government Gazette*; and two weekly, *The Bengal Herald*, and *The Oriental Observer*. (2. Native.) *Janrie Jehan Numa*, *Summachar Chunduca*, *Sunbad Tuneer Nassukh*, *Bunga Doot*, *Sunbad Coumoody*.¹ At this period every paper was published, under a license, revocable at pleasure, with or without previous inquiry or notice. But, in the words of Mr Sutherland, "Lord William Bentinck never interfered with the press, and it has been privately understood he never will do so." He was wont to say, according to another good authority, Mr Kaye, "I do not care a straw for the vituperations of the press; . . . but I have learned more from it than from all the other sources of information which have been open to me since I assumed the government of this country." At Madras, on the other hand, it remained under rigid restriction. The papers, said Mr Sullivan in 1832, "are submitted to the chief secretary before publication, and he runs his pen through . . . whatever may appear to him objectionable." The Madras censorship was removed whilst the parliamentary inquiry of 1832 was still pending. *The Bengal Hurkaru* was, at the date of Lord W. Bentinck's government, the journal of largest circulation, its average issue (daily edition and tri-weekly editions together) being 1500.

The press
under Lord
W. Ben-
tinck.

One question only, and that but for a brief interval, disturbed Lord William Bentinck's love of free discussion. The too famous "Half-Batta" measure led him to think that a resolute persistence in an unwise policy by the home government against the known convictions of the men actually at the helm in India, and an unfettered press, were two things that could scarcely co-exist. It was on this occasion that Sir Charles Metcalfe recorded his minute of September 1830, the reasoning of which amply justifies the assertion—"I have, for my own part, always advocated the liberty of the press, believing its benefits to outweigh its mischiefs; and I continue of the same opinion."

News-
papers.

This opinion was nobly carried out in the memorable law drafted by Mr (now Lord) Macaulay, and enacted by Sir Charles Metcalfe, as governor-general in 1835. Mr Macaulay's minute (16th April 1835) contained the pertinent question—"It is acknowledged that in reality liberty is, and ought to be, the general rule, and restraint the rare and temporary exception. Why, then, should not the form correspond with the reality? Why should our laws be so framed as to make it appear that the ordinary practice is in the highest degree oppressive, and that freedom can be enjoyed only by occasional connivance?" The law of 1835 totally abrogated the licensing system. It left all men at liberty to express their sentiments on public affairs, under the legal and moral responsibilities of ordinary life. It had the hearty approval of most Indian statesmen in the front rank. But it was as heartily condemned by the Court of Directors at home; and for Sir Charles Metcalfe, it virtually cancelled (as far as the East India Company was concerned) the honourable and eminent services of thirty-seven years.

Lord Met-
calfe's law
of 1835.

And, after all, the directors discovered that they dared not insist on a return to the system of licenses. The press increased in vigour and influence, and as unquestionably rose in character. There were, as there will always be, discreditable exceptions, in which bad men employed in the light of day energies which, under the old system, would have found their vent in underground channels. But in the main the results have vindicated the policy. Lord Metcalfe's law remained in force until the outbreak of the wretched Sepoy mutiny.

The Act No. XV. of 1857 is entitled, "An Act to regulate the establishment of Printing Presses; and to Restrain in certain cases the Circulation of Printed Books and Papers." Like that of 1823, on which it is closely modelled, it absolutely prohibits the keeping or using of printing-presses, types, or other materials for printing, in any part of the territories in the possession and under the government of the East India Company, except with the previous sanction and license of government." It also gives full powers for the seizure and prohibition from circulation of all books and papers, whether printed within the Indian territories or elsewhere.

Lord Can-
ning's law
of 1857.

The results of this licensing act have yet to be learned. It is enacted for one year from its date; and the Minutes of the government at Calcutta expressly deprecate the criticism of its policy, otherwise than as a temporary measure. But the Court of Directors, more cautiously, in the despatch approving it (26th August 1857), take occasion to say,—"We do not think it necessary at present to enter on the general question of the freedom of the press in India."

Whatever may be the eventual verdict of informed English opinion on the government of India by the Company, considered as a whole, there can be nothing premature in the assertion, that in their relations with the press, both the directors at home and the functionaries who have most fully

¹ We give precisely the unusual orthography which appears in the Company's edition of the Reports relating to India. According to Mr Wilson there were in 1846 eight native newspapers printed in Calcutta, besides others at the different presidencies.

Newton, Sir Isaac. enjoyed their confidence in India, have uniformly distrusted and dreaded free speech and unfettered discussion. But men whose names will long live in the veneration of the natives of India, as well as in the memories of their fellow-countrymen, are found to be on the other side. That they are so, is of good omen for the future.

(*Minutes of Evidence on the Affairs of the East India Company*, February to July 1832, i. 98-101; 166-180 (Company's edition); *Report of the Select Committee of House of Commons on the Affairs, &c.*, 16th August 1832, 31, 32 (ibid.); *Report from Select Committee on the Suppression of the Calcutta Journal*, 4th August 1834; *Minutes*, 85-168; *Appendix*, passim; *Second Report from Select Committee on Indian Territories*, 12th May 1853, 64-68; *Further Papers on the Mutinies in the East Indies*, 1857, No. 5, 89-96; *Returns relating to the Restriction of the Liberty of the Press in India*, 24th August 1857, passim; *Selections from the Papers of Lord Metcalfe*, 1855, 311 seq.; *The Oriental Herald*, 1824, i., 6-77, 123-142, 197-224; *Letters to the Marquis of Hastings on the Indian Press*, 1824, 61, &c.; *Memoirs and Correspondence of the Marquess Wellesley*, i. 281, ii. 128, seq.; *Wilson's History of British India, from 1805 to 1835*, 1848, iii. 581-585.)

NEWTON, SIR ISAAC, a distinguished mathematician and natural philosopher, was born at the manor house of Woolsthorpe, about half a mile to the west of Colsterworth, in Lincolnshire, and some six miles to the south of Grantham. His birth, which was premature, took place on the 25th of December, O. S. 1642. His father, Mr Isaac Newton, was proprietor of Woolsthorpe, worth about L.30 per annum, and farmed it with his own hands. His mother was Harriet Ayscough, the daughter of Mr James Ayscough, of Market-Overton, in Rutlandshire. They had been married only a few months when Mr Newton died, leaving his wife in a state of pregnancy. The posthumous child was so small that "they might have put him into a quart mug," and no expectation was entertained of his continuing to live. "Providence, however," as his biographer observes, "had otherwise decreed; and that frail tenement, which seemed scarcely able to imprison its immortal mind, was destined to enjoy a vigorous maturity, and to survive even the average term of human existence." Mrs Newton possessed a small property in Leicestershire, about three miles from Woolsthorpe, which raised her annual income to about L.80.

In consequence of the marriage of Mrs Newton to the Rev. Mr Smith of North Witham, she left her son Isaac under the charge of her mother. He received his early education at two day schools at Skillington and Stoke; and in his twelfth year he went to the public school at Grantham, taught by Mr Stokes, and was boarded at the house of Mr Clark, an apothecary. Here his attention was less occupied with his studies than with the mechanical amusements, in which he spent all his leisure hours. Models of wind-mills, water-clocks, and self-moving carriages, were executed by him in succession; and he contrived to amuse his schoolfellows with paper kites and paper lanterns, which he raised to great heights in the air.

From the play-things of his childhood, Newton made a rapid transition to higher amusements. The daily movements of the sun were traced upon the walls and roofs of the buildings at Woolsthorpe. By means of pins and lines he indicated the hours and half hours of his rude dials; and though he was now employed in tending the cattle, and going to the market at Grantham, yet he was often found studying mathematics under a hedge, or gleaning fragments of science from old books in Mr Clark's garret at Grantham. This inattention to the duties of the farm increased with his years, and his mother came to the resolution of giving him an academical education. After the preparation of a few

Here our slight survey of a wide subject must needs find pause. To say that the newspaper press, with all its ability and influence, is as yet but at the threshold of its career, is neither presumptuous nor hazardous. In Britain, as well as in America, the journals that unite the highest order of talents with a manifestly conscientious sense of responsibility for the use of them, do but put into stronger light the defects of their opposites. We as little believe that the newspaper, at its best, will ever supersede books and pulpits, as we have faith in the much-bruited but very silly assertion, that "a number of *The Times* contains more instruction than all Thucydides." Until the journalists and the readers of a country are alike imbued with the spirit of (at least) their national classics, neither the full powers nor the highest functions of journalism will be elicited. But when a public thus intellectually nurtured shall be daily addressed by a press plainly under the guidance of religious principle, then unquestionably the power of instilling the same thought, at the same moment, into thousands of minds will prove the mightiest of all the secular agents of civilization,—the most effective of all curbs on misgovernment, whether arising from the errors of rulers or the temporary excitements of popular majorities. (E. E.)

Newton,
Sir Isaac.

months at Grantham school he was sent to Cambridge, where he was admitted a subsizer of Trinity College on the 5th of June 1661, a bachelor of arts in 1665, a junior fellow in 1667, and master of arts in 1668. Young Newton's attention was first turned to the study of mathematics by a passion for judicial astrology. He considered the propositions in Euclid as self-evident truths; and in the geometry of Descartes, the *Miscellanies* of Schooten, the *Clavis* of Oughtred, and the *Arithmetic of Infinites* of Wallis, he acquired his first knowledge of the mathematics. Kepler's *Optics* and Saunderson's *Logic* were amongst the books which he carefully studied, and upon which he wrote comments; and so rapid was his progress in knowledge, that he was considered as being more deeply versed in several branches than his own tutor. In the year 1666 he purchased a prism for the purpose of studying Descartes' Theory of Colours; and early in 1668 three additional prisms, which were no doubt those used by him in his experiments. He had in 1666 applied himself to the grinding of "optic glasses of other figures than spherical;" and finding that there were other causes than the imperfect converging of rays to a focus which rendered refracting telescopes imperfect, he was led to inquire into the cause of the colours produced by lenses and prisms, and to make those splendid discoveries respecting the different refrangibility of the rays of light, the history and nature of which will be found in the article OPTICS.

Having despaired of improving the refracting telescope, Newton directed his attention to the reflecting one. At this time Gregory's *Optica Promota*, published in 1663, fell into his hands; and, in considering the construction of the Gregorian telescope there described, "he found the disadvantages of them so great," "that he altered the design of it, and placed the eye-glass at the side of the tube rather than at the middle." On this altered principle he executed a reflecting telescope with his own hands in the year 1668. In 1671 he finished a better one, which was shown to the king, and presented to the Royal Society, in whose custody it still remains.

Although Newton delivered a course of lectures on optics in Cambridge in 1669, 1670, and 1671, containing an account of his discoveries respecting the different refrangibility of the rays of light, yet the Royal Society was not acquainted with them till 1672. On the 23d of December 1671 he was proposed as a member of that body by Dr Seth Ward, bishop of Sarum, and he was elected on the

Newton, Sir Isaac. 11th of January 1672. On the 6th of February he communicated to Mr Oldenburg his discoveries respecting light, which he regarded as "the oddest, if not the most considerable, detection which had hitherto been made in the operations of nature."

No sooner was it communicated to the world that *white* light consists of seven different colours, having different degrees of refrangibility, than a crowd of obscure individuals assailed, not only his conclusions, but the accuracy of the experiments from which they had been derived. Dr Hooke and Huygens attacked them on different grounds; but Newton, in a letter to Oldenburg, dated the 11th of June 1672, silenced the arguments of his opponents, and established his general doctrine upon an impregnable basis.

The colours of thin plates, first observed by Boyle, and studied by Hooke, had occupied the special attention of Newton. The results of his inquiries were laid before the Royal Society on the 7th of December 1675, and about twelve years afterwards the theory of *fits* was completed, and applied to the explanation of the permanent colours of natural bodies. These researches, however, including his experiments on the inflexion of light, which he gives only as an imperfect fragment, were not published till 1704, when his treatise on Optics appeared. (See the article OPTICS).

The first idea of gravity as the cause of the celestial motions occurred to Newton in the year 1666, when sitting alone in the garden of Woolsthorpe. Conjecturing that it might extend as far as the moon, he was led to confirm the conjecture by calculation, and thus to establish the doctrine of universal gravitation, "that every particle of matter is attracted by, or gravitates to, every other particle of matter, with a force inversely proportional to the square of the distance." This great discovery, and its application to the movements of the planetary system, as well as to that of the comets, was published in 1686, in his *Philosophiæ Naturalis Principia Mathematica*, a work which, to use the words of Newton's biographer, "is memorable, not only in the annals of one science or one country, but will form an epoch in the history of the world, and will ever be regarded as the brightest page in the records of human reason." This remarkable production was speedily circulated over Europe; and although the discoveries which it contained were for a while opposed by national as well as personal jealousies, yet the Newtonian philosophy made rapid progress, and finally supplanted the rival systems of Aristotle and Descartes.

As early as the year 1666 Newton had discovered the binomial theorem and the method of fluxions; and although he had not communicated this discovery to any of his friends, yet he had clearly described the principle, and exhibited the application of his method, in his *Analysis per Equationes numero Terminorum infinitas*, a work which he had communicated to Dr Barrow in June 1669, and which

was not published till 1701, nearly half a century after it was written. Our readers are well aware that the discovery of fluxions was claimed by Leibnitz, and that the controversy which sprung out of this claim is scarcely yet at an end.¹

From the year 1669, when Newton was appointed to succeed Dr Barrow as Lucasian professor of mathematics at Cambridge, till 1688, he led a secluded life within the walls of his college; but events now occurred which drew him from retirement, and placed him conspicuously on the stage of public life. James II., desirous of re-establishing the Catholic faith as the national religion, had begun to assail the privileges of his Protestant subjects. He ordered Father Francis, an ignorant Benedictine monk, to be received at Cambridge as a master of arts, and the oaths of allegiance and supremacy to be dispensed with. The university resisted this illegal mandate, and chose nine delegates to defend their independence. Having joined in resisting the wishes of the court, Newton was chosen one of the delegates; and such was their firmness, and the argumentative weight of their representations, that the king was led to abandon his design. Newton's popularity was extended by the success of the delegates, and he was elected member for the university in 1688, along with Sir Robert Sawyer, having beaten Mr Finch by only five votes. Newton sat in the convention parliament from January 1689 till its dissolution in February 1690.

In the discharge of his parliamentary duties, he no doubt experienced the unsuitableness of his income to his new position. The limited means of his relations, and his own generous disposition, had exhausted his scanty resources, and he and his friends naturally looked to some patronage on the part of the government which might enable him to pursue his scientific researches, unembarrassed by those physical wants which have ever been the scourge of genius, and especially of that variety of it which is called forth by patient and continuous inquiry. There is ample evidence that unsuccessful applications had been made for this purpose; and the vexation and disappointment which this ingratitude produced, combined with other causes, seem to have thrown Newton into a state of nervous irritability, which threatened to paralyze even his mighty intellect. It is difficult to trace with distinctness the succession of causes which at this time contributed to disturb his serenity; but it has been said that, about the end of 1692, or early in 1693, his chemical laboratory had been burned, and a number of manuscripts destroyed; and on another occasion, several valuable manuscripts were consumed by a candle which he had left burning whilst he went to chapel. These losses seem to have affected him deeply, and "he was so troubled thereat, that every one thought he would have run mad, and he was not himself for months after." Another account of these events, communicated by one Colin or Collins to Huygens,² represents Newton as

¹ A full account of this controversy will be found in the article FLUXIONS, and in PRELIMINARY DISSERTATION IV., part ii., § 1. Many curious facts and documents recently brought to light will be found in Sir David Brewster's *Memoirs of the Life, Writings, and Discoveries of Sir Isaac Newton*, 1855, chaps. xiv. and xv.

² The following extract from the manuscript of Huygens was first published in Biot's *Life of Newton*:—"On the 29th of May 1694, M. Colin (Collins or Colm), a Scotsman, informed me that, eighteen months ago, the illustrious geometer Isaac Newton had become insane, either in consequence of his too intense application to his studies, or from excessive grief at having lost by fire his chemical laboratory, and several manuscripts. When he came to the Archbishop of Cambridge (Canterbury), he made some observations which indicated an alienation of mind. He was immediately taken care of by his friends, who confined him to his home, and applied remedies, by means of which he had now so far recovered his health that he began to understand the *Principia*." The M. Colin here mentioned was Mr Collins, the son of John Collins, the early friend of Newton. (See *Memoirs of Newton*, &c., 1855, vol. ii., p. 131, note.)

The following extract from a manuscript journal kept by Mr Abraham de la Pryme, an ancestor of Professor Pryme, when a student at Cambridge, throws much light on this part of Newton's life:—"1692, Feb. 3. What I heard to-day I must relate. There is one Mr Newton (whom I have very often seen), fellow of Trinity College, that is mightily famous for his learning, being a most excellent mathematician, philosopher, divine, &c. He has been fellow of the Royal Society these many years; and amongst many other very learned books and tracts, he has written one upon the mathematical principles of philosophy, which has got him a mighty name, he having received, especially from Scotland, abundance of congratulatory letters for the same. But of all the books which he ever wrote, there was one of *Colours and Light*, established upon thousands of experiments, which he had been twenty years of making, and which had cost him many hundreds of pounds. This book, which he valued so much, and which was so much talked of, had the ill luck to perish,

Newton, having actually become insane, and unable to understand Sir Isaac. his own writings; and, relying upon the accuracy of this statement, M. Biot and other French philosophers considered his insanity as the reason why Newton had ceased to make scientific discoveries. They even went so far as to ascribe his study of theology to this enfeebled state of mind, and thus to deprive our faith of that support which it derived from having been illustrated and defended by so great an expositor and champion.

That the mind of Newton was sound and active during the period when it is said to have been seriously disturbed, has been proved by many undoubted facts. In this interval he composed his four celebrated letters to Dr Bentley on the existence of a Deity; letters which evince a power of thought, and a serenity of mind, incompatible even with the slightest obscuration of his faculties. The *first* of these letters was written on the 10th of December 1692; the *second* on the 17th of January 1692-3; the *third* on the 11th of February, and the *fourth* on the 25th of February 1693-4. These letters were written in answer to some queries sent to him by Dr Bentley. After Dr Bentley had received the *third* letter, he sent to Sir Isaac an abstract of his first unpublished sermon, requesting him "to acquaint him with what he found in it not conformable to truth and his hypothesis;"¹ and it was to this letter that the *fourth* was a reply. In 1692 we find him also engaged in mathematical researches on the quadrature of curves, and in observations on halos; and in November and December 1693 he was occupied in discussing mathematical questions with his correspondents. On the 1st of September 1694 Newton visited Flamsteed at Greenwich, and he was at that time occupied with the difficult and profound subject of the lunar theory, and with his fine theory of astronomical refractions.

That Newton's health was affected from the middle of 1692 to the middle of 1693, is quite certain; and that his nervous system was shaken by loss of sleep and appetite, is mentioned by himself. Exaggerated rumours had reached his friends in London, and Mr Pepys was led to inquire if these rumours of a discomposure of his mind had any foundation. Mr J. Millington, who was tutor of Magdalene College, returned the following answer:—"I was, I must confess, very much surprised at the inquiry you were pleased to make by your nephew about the message that Mr Newton made the ground of his letter to you, for I was very sure I never either received from you or delivered to him any such; and, therefore, I went immediately to wait upon him, with a design to discourse with him about the matter; but he was out of town, and since I have not seen him, till, upon the 28th, I met him at Huntingdon, where, upon his own accord, and before I had time to ask him any question, he told me that he had writt to you a very odd letter, at which he was much concerned; added, that it was in a distemper that much seized his head, and that kept him awake for about five nights together, which, upon occasion, he desired I would represent to you, and beg your pardon, he being very much ashamed he should be so rude to a person for whom he hath so great an honour. He is now very well, and though I fear he is under some small degree of melancholy, yet I think there is no reason to suspect it hath at all touched his understanding, and I hope never will; and so I am, sure all ought to wish that love learning, or the

honour of our nation, *which it is a sign how much it is looked after*, WHEN SUCH A PERSON AS MR NEWTON LYES NEGLECTED BY THOSE IN POWER."

In the beginning of the year 1692, Charles Montague, Lord Monmouth, and Mr Locke, were exerting themselves to obtain some appointment for Newton. In his letters to Locke, Newton himself refers, with a considerable degree of feeling, to these exertions. He conceived that Charles Montague, under the influence of some old grudge, had been false to him, and that there had been a design to sell him an office; and it is to the failure of these attempts that Mr Millington alludes with such just severity in the letter which we have quoted.

Newton was now in the fifty-third year of his age; and whilst those of his own standing at the university had been appointed to high stations in the church, or to lucrative offices in the state, he still remained without any mark of national gratitude. His fellow-labourers in science in every part of Europe were enjoying the favour and protection of their respective sovereigns, who had even invited foreign philosophers to their capitals to enjoy the liberality which they had extended to their own. Foreigners viewed with astonishment the treatment of Newton by his own sovereign, and in 1698 the French king had the nobleness of mind to offer him, through Cassini, a liberal pension.

But this blot upon the English name was at last removed by Charles Montague when, in the year 1694, he was appointed chancellor of the exchequer. He had previously consulted Mr Newton upon the subject of the recoinage; and when Mr Overton, the warden of the mint, was made a commissioner of customs, he served both his friend and his country by appointing Newton to that important office. "I am very glad," says he, "that *at last* I can give you a good proof of my friendship, and the esteem the king has of your merits. Mr Overton, the warden of the mint, is made one of the commissioners of the customs, and the king has promised me to make Mr Newton warden of the mint. The office is the most proper for you. 'Tis the chief office in the mint; 'tis worth five or six hundred pounds per annum, and has not too much business to require more attendance than you can spare."

The chemical and mathematical knowledge of Newton proved of great use in carrying on the recoinage, which was completed in about two years; and such was the zeal and devotion with which Newton discharged the laborious duties of this office, that he was appointed, in 1697, to the mastership of the mint, which was worth between twelve and fifteen hundred pounds per annum. In this situation he drew up a table of assays of foreign coins, and composed an official report on the coinage. Having retained his professorship at Cambridge whilst he was warden, he now appointed Mr Whiston as his deputy, with all the emoluments of the chair.

In 1660 Newton was elected a Foreign Associate of the Royal Academy of Sciences at Paris, along with Leibnitz and the two Bernoullis. In 1701 he was elected one of the members of Parliament for the University of Cambridge. In 1703 he was raised to the presidency of the Royal Society of London, to which he was annually re-elected during the remaining twenty-five years of his life.

When Queen Anne and the court visited Cambridge on the 16th of April 1705, she conferred the honour of knighthood on Mr Newton.

and be utterly lost, just when the learned author was almost at putting a conclusion to the same, after this manner. In a winter's morning, leaving it among his other papers on his study table, whilst he went to chapel, the candle, which he unfortunately left burning there too, caught hold by some means of other papers, and they fired the aforesaid book and utterly consumed it, and several other valuable writings; and, which is most wonderful, did no further mischief. But when Mr Newton came from chapel, and had seen what was done, every one thought he would have run mad; he was so troubled thereat, that he was not himself for a month after." (Brewster's *Life of Newton*, 1831, p. 228.)

¹ The interesting letter containing this request has been published for the first time in the *Memoirs of Newton*, &c., 1855, vol. ii., App. x., p. 463.

Newton,
Sir Isaac.

Newton,
Sir Isaac.

On the dissolution of Parliament in 1705, Sir Isaac was again a candidate for the representation of the university; but he was beaten by a great majority. He was supported by all the resident members; but being a Whig in politics, and the cry of the church in danger having been raised on that occasion, he became the victim of the ignorance and fanaticism of the non-resident constituency.

The first edition of the *Principia* having been sold off, Dr Bentley and his other friends had, for a considerable time, been urging Sir Isaac to prepare a new edition. The duties of the mint would not permit him to devote much time to such a task; but he willingly complied with the request of his friends, when Mr Roger Cotes, Plumian professor of astronomy at Cambridge, undertook to superintend its publication. Newton promised to send his own revised copy to Mr Cotes in July 1709; but delays took place, and the work was not completed till the spring of 1713. Nearly three hundred letters—passed between Sir Isaac and Cotes, and in which the various alterations and additions are discussed—have been preserved in the library of Trinity College, Cambridge, and published by Mr Edleston in 1850.

When George I. succeeded to the throne of Great Britain, Sir Isaac became an object of interest at court. The Princess of Wales, afterwards queen-consort to George II., took great pleasure in conversing with him, and in corresponding with Leibnitz. Having one day mentioned to her Royal Highness a new system of chronology which he had composed while resident at Cambridge, she requested Sir Isaac, through the Abbé Conti, to give her a copy of it. He accordingly drew up an abstract of it from the loose papers to which it had been committed, and sent it to the princess for her private use alone. He afterwards allowed a copy to be given to the Abbé Conti, on the condition of its not being communicated to any person whatever. The abbé, however, forgetting his obligation, communicated it to M. Fréret, a learned antiquary in Paris, who translated it, and endeavoured to refute it. It was printed early in 1725, under the title of *Abrégé de Chronologie de M. le Chevalier Newton, fait par lui-même, et traduit sur le Manuscrit Anglais*. Upon receiving a copy of this work, Sir Isaac Newton printed, in the *Philosophical Transactions* for 1725, a paper entitled, "Remarks on the observations made on a Chronological Index of Sir Isaac Newton, translated into French by the observator, and published at Paris." In these remarks Sir Isaac charges the abbé with a breach of promise, and gave a triumphant answer to the objections which Fréret had urged against his system. Father Souciet entered the field in defence of Fréret; and in consequence of this controversy, Sir Isaac was induced to prepare his larger work, which was published in 1728, after his death, and entitled the *Chronology of Ancient Kingdoms amended; to which is prefixed a short Chronicle from the First Memory of Kings in Europe to the conquest of Persia by Alexander the Great*.

There is no part of Sir Isaac Newton's biography more remarkable than that which relates to his theological studies. From a very early period of his life Newton had seriously embarked in the study of theology. Previously to 1692 he was known by the appellation of an excellent divine, and it is well known that he had begun to study the subject of the prophecies before 1690; whereas, in order to show that his theological writings were the productions of his dotage, and subject to his supposed mental alienation, M. Biot has fixed their date between 1712 and 1719, between the seventieth and the seventy-seventh year of his age.

One of the most remarkable of Sir Isaac's theological productions is his *Historical Account of Two Notable Cor-*

ruptions of the Scripture, in a letter to a friend. This friend was Mr Locke, who received the letter in November 1690. Sir Isaac seems to have been then anxious for its publication; but as the effect of his argument was to deprive the Trinitarians of two passages in favour of the Trinity, he became alarmed at the probable consequences of such a step. He therefore requested Locke, who was then going to Holland, to get it translated into French, and published on the Continent. Being prevented from going to Holland, Locke copied the manuscript, and sent it, without Newton's name, to M. le Clerc, who received it before the 11th of April 1691. On the 20th of January 1692, Le Clerc announced to Locke his intention to publish the pamphlet in Latin; and upon intimating this to Sir Isaac, he entreated him "to stop the translation and impression as soon as he could, for he designed to suppress them." This was according done; but Le Clerc sent the manuscript to the library of the Remonstrants, and it was afterwards published at London in 1754, under the title of *Two Letters from Sir Isaac Newton to M. le Clerc*. This edition is imperfect, and in many places erroneous. Dr Horsley therefore published a genuine one, which is in the form of a single letter to a friend, and was taken from a manuscript in Sir Isaac's own hand, in the possession of the Reverend Dr Ekins, dean of Carlisle.¹

Sir Isaac Newton left behind him in manuscript a work entitled *Observations on the Prophecies of Daniel and the Apocalypse of St John*, which was published in London in 1733, in one volume 4to; another work entitled *Lexicon Propheticum*, with a dissertation on the sacred cubit of the Jews, which were printed in 1737; and Four Letters addressed to Dr Bentley, containing some arguments in proof of a Deity, which were published by Mr Cumberland, the nephew of Dr Bentley, in 1756.² Sir Isaac also left a Church History complete; a History of the Creation; Paradoxical Questions regarding Athanasius, and many divinity tracts.

Sir Isaac Newton devoted much of his time to the study of chemistry; but the greater number of his experiments still remain in manuscript. His *Tabula Quantitatum et Graduum Caloris* contains a comparative scale of temperature from that of melting ice to that of a small kitchen coal fire. He wrote also another chemical paper, *De Natura Acidorum*, which has been published by Dr Horsley. Sir Isaac spent much time in the study of the works of the Alchemists. He had diligently studied the works of Jacob Behmen, and there were found amongst Sir Isaac's manuscripts copious abstracts from them in his own handwriting. In the earlier part of his life he and his relation Dr Newton of Grantham had put up furnaces, and had wrought for several months in quest of the philosopher's tincture. These views are rendered more probable by the fact, that among the manuscripts in the possession of the Earl of Portsmouth, there are many sheets, in Sir Isaac's hand, of Flamsteed's Explication of Hieroglyphic Figures, and in another hand many sheets of William Yworth's *Processus Mysterii Magni Philosophicus*.

Amongst the inventions of Sir Isaac Newton we must enumerate his reflecting telescope, his reflecting microscope, a sextant similar to Hadley's, and his prismatic reflector, with plane and convex surfaces. We owe also to him some very interesting views on the decussation of the optic nerves, which were first published in Harris's *Optics*; a hypothesis respecting ether as the cause of light and gravity; and some experiments upon the excitation of electricity on glass.³

The sale of the second edition of the *Principia* having been rapid, a third edition was called for in 1722. Roger

Newton,
Sir Isaac.

¹ See Brewster's *Life of Newton*, 1831, p. 276.

² *Newtoni Opera*, by Horsley, vol. iv., p. 375.

³ The original letters are preserved in the library of Trinity College, Cambridge.

Newton, Cotes had died in the prime of life, and therefore Newton engaged Dr Pemberton to superintend the new edition, which was published in 1726, with numerous alterations.¹

During the last twenty years of Sir Isaac's life, his beautiful and accomplished niece, Miss Catherine Barton, had managed his domestic concerns. She was the daughter of Mr Robert Barton of Brigstock, and of Hannah Smith, Newton's half sister. She had been a great favourite of Charles Montague, Earl of Halifax, who, at his death in 1715, bequeathed to her a very large portion of his fortune. This lady, who had been educated at Sir Isaac's expense, married Mr Conduit, and continued to reside with her husband in Sir Isaac's house until the time of his death. Although the liberality of Lord Halifax to Mrs Barton surprised her contemporaries, yet she was regarded by all who knew her as a woman of strict honour and virtue. As the niece of Newton, and the wife of Mr Conduit, his successor in the mint, she moved in the highest circles; and during the century which has elapsed since her death, it has never even been supposed that her connection with Halifax was impure. Professor De Morgan, however, has recently attempted to show that she must either have been the wife or the mistress of that nobleman; and as there is not the slightest proof of a marriage, we are forced by this groundless hypothesis to take the most painful view of her character. Regarding this opinion as derogatory to the character of Newton, his biographer has shown, in the most satisfactory manner, that there is no foundation whatever for the opinion that Mrs Barton was either the wife or the mistress of Halifax, and has restored her to her high position as the niece of Newton, and the female head of the noble house of Portsmouth.

In the year 1722, when Sir Isaac was eighty years old, he had been seized with an incontinence of urine, which was ascribed to stone. By great attention to diet and regimen he succeeded in keeping down this dreadful malady; but in August 1724 he passed a small stone, and for some months enjoyed a tolerable degree of health. In January 1725 he was seized with a violent cough and inflammation of the lungs, which induced him to reside at Kensington; and in the February of the same year he had a fit of gout both in his feet and hands, which produced a decided improvement in his general health. His duties at the mint were discharged by Mr Conduit, and he therefore seldom went from home. Feeling himself well, he went to London on the 28th of February 1728, to preside at a meeting of the Royal Society; but the fatigue which attended this duty brought on a violent return of his former complaint, and he returned to Kensington on the 4th of March, when Dr Mead and Dr Chesselden pronounced his disease to be stone. He endured the sufferings of this complaint with wonderful patience and meekness. He seemed a little better on the 15th of March, and on the 18th he read the newspapers and conversed with Dr Mead; but at six o'clock in the evening he became insensible, and continued in that state till Monday the 20th of March, when he expired without pain between one and two o'clock in the morning, in the eighty-fifth year of his age. His body was removed to London, and on Tuesday the 28th of March it lay in state in the Jerusalem Chamber, and was thence conveyed to Westminster Abbey, where it was buried near the entrance into the choir, on the left hand. The pall was supported by the Lord Chancellor, the Dukes of Roxburghe and Montrose, and the Earls of Pembroke, Sussex, and Macclesfield, who were fellows of the Royal Society, the Hon. Michael Newton, K.B., was chief mourner. The Bishop of Rochester performed the funeral service. The relations who inherited his personal estate devoted L.500 to the

erection of a monument to his memory. It was finished in 1731, and was erected in the centre of the abbey. The following is the epitaph inscribed upon it:—

Newton,
Sir Isaac.

Hic situs est
Isaacus Newton, Eques auratus,
Qui animi vi prope divina
Planetarum motus, figuras,
Cometarum semitas, Oceanique Æstus
Sua Mathesi facem præferente
Primus demonstravit;
Radiatorum Lucis dissimilitudines
Colorumque inde nascentium proprietates
Quas nemo antea vel suspicatus erat, pervestigavit;
Naturæ, antiquitatis, S. Scripturæ
Sedulus, sagax, fidus interpres;
Dei opt. max. majestatem philosophia asseruit;
Evangelii simplicitatem moribus expressit.
Sibi gratulentur mortales, tale tantumque extitisse,
HUMANI GENERIS DECUS
Natus xxv. Decemb. MDCXLII; Obiit xx. Mar.
MDCCLXXVII.

In the beginning of the year 1731, a medal was struck at the Tower in honour of Sir Isaac Newton, bearing the motto *Felix cognoscere causas*; and on the 4th of February 1755 a fine full-length statue of him by Roubillac, executed in white marble, was erected in the antichapel of Trinity College, Cambridge, at the expense of Dr Robert Smith, the author of the *Complete System of Optics*. The pedestal bears the inscription from Lucretius,—

Qui genus humanum ingenio superavit;

a eulogium which may be questioned even by those who are the greatest admirers of Newton's genius.

The personal estate of Sir Isaac Newton amounted to about L.32,000. It was divided amongst his four nephews and four nieces of the half blood, the grandchildren of his mother by the Rev. Mr Smith. The family estates of Wools-thorpe and Suster were bequeathed to John Newton, whose great-grandfather was Sir Isaac's uncle, by whom they were sold in 1732 to Mr Edmund Turnor of Stoke Rocheford. Sir Isaac bequeathed his estate at Kensington to Catherine, the only daughter of Mr Conduit, who afterwards married Mr Wallop, the eldest son of Lord Lymington, and subsequently Earl of Portsmouth. Sir Isaac was succeeded as warden and master of the mint by his nephew, Mr Conduit, who died in 1737.

In his social character Sir Isaac Newton was modest, candid, and affable, accommodating himself to every class of society in which he moved. His humility was that of a philosopher who had experienced both the strength and the weakness of the human mind, and of a Christian who was deeply impressed with the unsatisfying nature of all earthly greatness. "I do not know," said he, a short time before his death, "what I may appear to the world; but to myself I seem to have been only like a boy playing on the sea-shore, and diverting myself in now and then finding a smoother pebble or a prettier shell than ordinary, whilst the great ocean of truth lay all undiscovered before me." His religious and moral character were equally admirable. He was deeply versed in the knowledge of the Scriptures, and was not equalled in point of theological learning by any of the divines of his age. He was a great friend of religious toleration, and never scrupled to express his abhorrence of even the mildest species of religious persecution.

Sir Isaac Newton was remarkable for his liberality upon all occasions. His charity was boundless; and he was in the habit of remarking, that those who gave away nothing till they died never gave at all. He wrote to the Provost of Edinburgh in 1724, offering L.20 annually to Mr Mac-

¹ Pemberton's letters to Newton are among the Portsmouth papers. See Brewster's *Memoirs*, &c., 1855, vol. ii., p. 380.

Newton,
Sir Isaac.

laurin, provided he became assistant to Mr James Gregory, professor of mathematics in the university. In 1719 he gave fifty guineas to the Rev. Mr Pound, who made some astronomical observations for his use; and in 1720 he gave him the like sum. He likewise bestowed large donations on the Ayscoughs, his relations.

In his personal appearance Sir Isaac was not above the middle size. He had "a comely and gracious aspect, and a very lively and piercing eye." He was short-sighted, but never wore spectacles, nor lost more than one tooth in his life. Bishop Atterbury asserts, in opposition to this, that the lively and piercing eye did not belong to Sir Isaac during the last twenty years of his life. "Indeed," says he, "in the whole air of his face and make there was nothing of that penetrating sagacity which appears in his compositions. He had something rather languid in his look and manner, which did not raise any good expectation in those who did not know him."

There is some reason to believe that Sir Isaac Newton was of Scottish descent, although in the pedigree which he gave into the Herald's Office he stated that *he had reason to believe* that he was descended from the Newtons of Westby. There is, however, ample evidence of the fact that Newton mentioned to David Gregory that it was a tradition in his family that his grandfather was a gentleman in East Lothian; and it has been placed beyond a doubt, that Newton himself wrote to Scotland to ascertain if any descendants of the family remained.¹

The manor-house of Woolsthorpe, as well as every other memorial of Sir Isaac, has been preserved with religious care. Mr Edmund Turnor of Stoke Rocheford put up in 1798 a white marble tablet in the room where Sir Isaac was born, recording his birth and death, and bearing the celebrated lines of Pope:—

"Nature and Nature's laws lay hid in Night;
God said, 'Let Newton be,' and all was light."

The house still contains on its walls the two dials made by Newton himself, but without the styles. His second telescope is preserved in the library of the Royal Society; and his globe, universal ring dial, quadrant, compass, and a reflecting telescope said to have belonged to him, in the library of Trinity College, Cambridge.

The manuscripts, correspondence, and other papers of Sir Isaac Newton, have been preserved in different collections. But the most important collection is the family one in the possession of the Earl of Portsmouth. They are deposited at Hurtsbourne Park, his lordship's seat in Hampshire, and were examined in 1837 by the late H. A. Fellowes, Esq., the accomplished nephew of Lord Portsmouth, and by Sir David Brewster, who has been permitted to make use of them in composing *Memoirs of the Life, Writings, and Discoveries of Sir Isaac Newton*. In this examination much new and valuable information has been discovered relative to the early life of Sir Isaac, which had been collected by his nephew-in-law Mr Conduit, for the purpose of writing a life of him, which he was prevented from executing by his death in the year 1737.² Many letters and papers of Newton are in the possession of the Earl of Macclesfield at Shirburn. They were found amongst the papers of William Jones, the friend of Sir Isaac, and the father of Sir William Jones. These papers were put into the hands of the late Professor Rigaud of Oxford, and were published in 1841, by his son, in two volumes.

About thirty-four of Newton's letters to Flamsteed are deposited in the library of Corpus Christi College, Oxford; but a large portion of the correspondence between Newton

and Flamsteed was found a few years since by Mr Baily in the possession of Mr Giles, a private gentleman in London, and in the Royal Observatory at Greenwich, along with various important documents intimately connected with the scientific history of that period. As the papers found in the observatory had been purchased by the Board of Longitude in 1771, the Lords Commissioners of the Admiralty, on the recommendation of the Board of Visitors of the Royal Observatory, agreed to print them. They have been accordingly printed in a large 4to volume, under the superintendence of Mr Baily.³

Doubts have been entertained by some, and openly expressed by others, on the propriety of publishing all the papers contained in this collection. Several of the letters of Flamsteed, and various parts of his autobiographical memoir, contain bitter and malignant attacks upon the character and conduct of Sir Isaac Newton, which, if they had been published during his life, or not long after it, might have been refuted on the authority of documentary and other evidence. Fortunately for the memory of Sir Isaac Newton, his generous and noble character, his meek and gentle disposition, and his Christian forbearance and patience, form a secure shield against the reckless and wanton charges of his irritable and violent assailant. If reflections have been cast on the character of Newton by the animadversions of Flamsteed, the conduct of the latter has been exposed to a scrutiny which it may not be able to sustain; and the friends of Newton have been reluctantly compelled to collect the opinions which contemporary writers had expressed of Flamsteed, in order to enable the public to form a just estimate of the testimony which he has borne against his fellow-labourer in science.

Those who wish to know more of the differences between Newton and Flamsteed, may consult the volume above mentioned, which is entitled "*An Account of the Rev. John Flamsteed, the first Astronomer Royal, compiled from his own manuscripts, and other authentic documents never before published; to which is added, his British Catalogue of Stars, corrected and enlarged, printed by order of the Lords Commissioners of the Admiralty, London, 1835.*" Mr Baily, at his own expense, published, in January 1837, a supplement to this work, which he distributed amongst those persons and institutions only to whom the original work was presented." Much light has been recently thrown upon this controversy by the letters of Flamsteed to Newton, and other documents, which Newton had carefully preserved, and which were found among the Portsmouth papers by Sir David Brewster. These documents have enabled his biographer to defend him against the virulent attacks of Flamsteed.

(See Brewster's *Memoirs of the Life, Writings, and Discoveries of Sir Isaac Newton*, Edinburgh, 1855, 2 vols.; and Edleston's *Correspondence of Sir Isaac Newton and Professor Cotes*, 1850.) (D. B.)

NEWTONIAN PHILOSOPHY, the doctrine of the universe, and particularly of the heavenly bodies, their laws, affections, &c., as delivered by Sir Isaac Newton.

The term *Newtonian Philosophy* is applied very differently. Some authors under this denomination include all the corpuscular philosophy, considered as it now stands corrected and reformed by the discoveries and improvements made in several parts of it by Sir Isaac Newton. In this sense it is that's Gravesande calls his elements of physics *Introductio ad Philosophiam Newtonianam*: and in this sense the Newtonian is the same with the new philosophy, standing contradistinguished from the Cartesian, the Peri-

Philosophy.

¹ See *Memoirs of Newton, &c.*, 1855, vol. ii., App., pp. 540-546.

² These papers have been more recently entrusted to Sir David Brewster, who has published the most important of them, in 1855, in the *Memoirs of Newton* above referred to.

³ This volume was not published. The whole impression, which was small, was distributed in presents to scientific institutions, public libraries, and individuals interested in the subjects to which it relates.

patetic, and the ancient corpuscular system. By Newtonian philosophy others mean 'the method or order which Sir Isaac Newton observes in philosophizing, viz., the reasoning and drawing of conclusions directly from phenomena, exclusive of all previous hypotheses; the beginning from simple principles, deducing the first powers and laws of nature from a few select phenomena, and then applying those laws, &c., to account for other things. And in this sense the Newtonian philosophy is the same with the *experimental* or *inductive philosophy*, and stands opposed to the ancient corpuscular system. By this philosophy some understand that particular kind in which physical bodies are considered mathematically, and where geometry and mechanics are applied to the solution of the appearances of nature. In this sense the Newtonian is the same with the *mechanical* and *mathematical philosophy*. Others, again, by Newtonian philosophy, understand that part of physical knowledge which Sir Isaac Newton has handled, improved, and demonstrated in his *Principia*. Lastly, by it is meant the new principles which Sir Isaac Newton has brought into philosophy, the new system founded thereon, and the new solutions of phenomena thence deduced, or that which characterizes and distinguishes his philosophy from all others; and this is the sense in which it ought to be used. (See the articles ASTRONOMY, ATTRACTION, DYNAMICS, OPTICS; Professor Playfair's Dissertation, part ii., sect ii.; and Sir John Leslie's Dissertation, sect. vii.)

NEWTON, *Gilbert Stuart*, an artist, was born at Halifax in Nova Scotia in 1794. His lessons in painting were begun at Boston under his maternal uncle, and were finished in London at the Royal Academy. The laborious and fastidious style in which he prosecuted his art soon brought him into notice. He first became known by his paintings of "The Forsaken" and "The Lovers' Quarrel," which were engraved in the *Literary Souvenir* for 1826. "The Prince of Spain's visit to Catalina" and "Macheath" raised him soon afterwards to the height of his reputation. His picture of "Abelard" followed in 1833. Shortly after this he became subject to mental aberrations, which grew in course of time into positive insanity. A few days, however, before his demise his reason returned, and he died in perfect consciousness at Chelsea in August 1835. Newton was a member of the Royal Academy. Some of his other pictures are,—“Shylock and Jessica,” “Yorick and the Gristle,” “The Abbot Boniface,” “Portia and Bassanio,” and “Lear attended by Cornelia and the physician.”

NEWTON, *John*, an English divine, remarkable for his trials and adventures, and for the deep piety of his after life, was the son of a sea-captain, and was born in London in July 1725. After receiving a slight elementary education at a boarding establishment in Essex, he went to sea at the age of eleven; and from that time he was left to teach himself in the severe school of experience. The sensitive and thoughtful boy now became the prey of conflicting doubts and difficulties. For the next six years the religious impressions which he had received by the knee of his mother were in a continual struggle with the suggestions of atheistical books and scoffing companions. He became by turns a reader of the Bible and a student of Shaftesbury—a Pharisæical ascetic and a daring blasphemer—a remorseful penitent and a callous sceptic. At length, in his nineteenth year, his life assumed a more hopeful aspect. A passionate attachment which he then formed for a young Kentish maiden, who afterwards became his wife, began to restore the health and geniality of his heart; and his unexpected promotion in the following year to the rank of a midshipman on board the Havre man-of-war, afforded additional motives for good conduct. Yet the self-willed seaman soon entailed upon himself a long series of tormenting troubles. Taking it into his flighty brain to abandon his ship while she still lay at Plymouth, he was caught, brought back, flogged, and

Newton,
John.

degraded. He set sail for India in 1745 a common sailor, taunted by his messmates, frowned upon by his superiors, and fuming with disappointment, remorse, and revenge. At Madeira a Guinea vessel took him in exchange for another. But in the course of six months he was fain to be landed a penniless adventurer on the African coast near Sierra Leone. Employment was soon found in the service of a slave trader in one of the Islands of the Plantanes. But the severity of the climate, and the cruelty of his master's black concubine, turned that employment into the most grovelling bondage. A year had not passed before the stout English sailor was transformed into a spiritless, half-naked wretch, suffering under the effects of fever, shivering under the wind and wet of the rainy season, devouring the nauseous roots which he stole by night from the plantations, or the fish which he caught by the sea-shore, and exciting the contempt and even the pity of the meanest of the slaves. Still more degrading did his condition become when he had been hired by a more merciful master. An English captain arriving at Sierra Leone in February 1747 with orders from his father to bring him home, found Newton herding contentedly with the Negroes in their low pleasures and gross superstitions; and it was only the thought of the fair maiden in Kent that could induce him to embark for his native land. The perils of this homeward voyage brought at length the severe moral training of Newton to a successful issue. On a March evening in 1748 he found himself on board a struggling and half-foundered vessel in the midst of the raging Atlantic; his sceptic indifference and blaspheming braggardism deserted him at the near prospect of death; the truths of the gospel, after a season of doubt, recommended themselves to his trembling spirit; and, when the ship reached Ireland four weeks afterwards, he stepped on shore an altered man. The life of Newton now for the first time became bright with the smiles of fortune. In 1750 his long-continued attachment to Mary Catlett was ratified by marriage, and he was shortly afterwards appointed commander of an African slaver. It was at this time also that those studies began to be prosecuted which trained and prepared his mind for the clerical office. On shore, during the intervals between his different voyages, and on deck when his ship was bounding before the breeze, he was fond of poring over Horace, Livy, Buchanan, and Erasmus. After a sudden stroke of illness in 1754 had forced him to exchange a seafaring life for the office of a landing waiter in the customs at Liverpool, he extended his studies to Greek and Hebrew, and the best theological works in Latin, French, and English. At length, in 1764, he was ordained, and was appointed curate of the parish of Olney. His pastoral labours were not followed by so much fruit as might have been expected. With his healthy piety, indeed, he did much to relieve the melancholy of the poet Cowper, and to form the religious opinions of the commentator Scott. But his kind-hearted liberality and his practical home-thrusts were alike spent in vain upon the senseless and profligate boors of the parish. It was not until he had been presented to the rectory of St Mary Woolnoth, London, in 1779, that he became one of the great instruments in dispelling the religious apathy of that age. The public were already in possession of his autobiography and of many of his letters; and they now began to regard him as a living proof of the efficacy of evangelical Christianity. This impression was increased and perpetuated by the earnest, simple-hearted zeal of his pulpit ministrations. He continued to preach thrice a week, even when he was bending under a weight of more than fourscore years, and his sight, hearing, and memory were fast failing. His friends entreated him to stop: "What!" he exclaimed, "shall the old African blasphemer stop while he can speak?" He died not long afterwards, in December 1807.

Newton-
Ards.

A second edition of John Newton's works, containing his Autobiography, the *Omicron Letters*, the *Cardiphonia*, *A Review of Ecclesiastical History*, the *Olney Hymns*, and numerous sermons, discourses, tracts, and miscellaneous writings, were published in 6 vols. 8vo, London, 1816. His *Life*, by the Rev. Richard Cecil, was published in Cecil's Works, 4 vols. 8vo, London, 1811, and has also been printed separately.

NEWTON, Thomas, Bishop of Bristol, and Dean of St Paul's, was born on the 1st of January 1704. He was educated at Lichfield and Westminster; and had his university course at Trinity College, Cambridge, where he took his degree in arts, and attained to the rank of a fellow. He took clerical orders in 1729; and after holding a curacy at St George's, Hanover Square, London, he received his first preferment at Grosvenor Chapel, South Audley Street. In the spring of 1744 he was, through the interest of the Earl of Bath, his great friend and patron, presented to the rectory of St Mary-le-Bow. He took his doctor's degree in 1745; and in the spring of 1747 he was chosen lecturer of St George's, Hanover Square. In 1749 he published his edition of Milton's *Paradise Lost*, with notes from various authors, 2 vols. 4to, which was well received by the public, and by 1775 had gone through eight editions. His next performance of any note was his *Dissertations on the Prophecies*, 3 vols. 8vo, 1754-8; a work not characterized by very great profundity, either of thought or learning, but which nevertheless attained a wide popularity. They were translated into the German and Danish languages, and received the warmest encomiums from persons of learning and rank. In 1757 he was made prebendary of Westminster, dean of Salisbury, and sub-almoner to His Majesty. Four years afterwards he kissed the royal hand for his bishopric of Bristol; and in 1768 was made dean of St Paul's. Newton's health had never been robust; and after enduring great physical prostration for some time, he died in 1782, in the seventy-eighth year of his age. A complete edition of the bishop's writings, including numerous sermons and dissertations not referred to above, appeared, with an autobiography of the author, in 3 vols. 4to, London, 1782.

NEWTON, a township of England, county of Chester, situated on the slope of a hill, 8 miles E. by S. of Manchester, and $5\frac{1}{2}$ N.E. of Stockport. It has a parish church in the Norman style, two Methodist churches, and several schools. The manufacture of cotton is carried on here, and employs the greater part of the population. Pop. (1851) 7481.

NEWTON-ABBOT, a market-town of England, Devonshire, pleasantly situated on a hill near the right bank of the Lemon, 14 miles S.S.W. of Exeter. It contains a handsome town-hall; a parish church; Independent, Baptist, and Methodist churches; and several schools. Tanning and shoemaking are the principal manufactures of the place; and there is also some trade, principally in the exportation of shoes to Newfoundland. The market-days are Wednesday and Saturday; and three yearly fairs are held here. In this place William III. made his first public declaration after his landing in this country in 1688. Pop. (1851) 3147.

NEWTON-ARDS, a seaport-town of Ireland, in the county of Down, situated at the head of Lough Strangford, 10 miles E. of Belfast. It is regularly laid out and well built, having a market-place, and a principal street lined with many good houses. The old church, now used as a court-house, though somewhat dilapidated, is a fine building, entered by a beautifully-carved Norman doorway. It was completed in 1632, though it probably existed before that time, and was then only repaired. The present church, an elegant building, was erected in 1817. There are numerous other churches, belonging to Presbyterians, Methodists, Roman

Catholics, and Unitarians. Newton has also a large town-hall, with assembly-rooms in connection with it; several schools; a fever hospital, dispensary, and workhouse. The weaving and embroidery of damask muslins is the principal branch of industry carried on here; but there is also an extensive brewery in the town. In the neighbourhood there are some good stone quarries and lead mines. Pop. (1851) 9567.

NEWTON-IN-MAKERFIELD, or *in-the-Willows*, a market-town of England, county of Lancaster, 15 miles E. by N. of Liverpool, and about the same distance W. of Manchester. It has one principal street, which is broad, and lined with good houses; and on the site of the ancient market-cross an obelisk now stands. It possesses a neat parish church with a spire; an Independent chapel; and several schools. Cotton-mills, iron-foundries, glass-works, alkali-works, and brick-kilns are the principal manufactories, and give employment to the inhabitants. Races are held annually on a common not far from the town. Pop. 3126.

NEWTON-STEWART, a market-town of Scotland, county of Wigtown, on the right bank of the Cree, which is here crossed by a bridge of five arches, 7 miles N. by W. of Wigtown. It has a good town-hall; a large Gothic parish church; Free, United Presbyterian, Reformed Presbyterian, and Roman Catholic churches; and several schools. The inhabitants are employed to a large extent in the lead mines which are worked in the neighbourhood; and brewing, tanning, the manufacture of woollen and cotton stuffs, and the curing of bacon, are carried on in the town. Pop. (1851) 2199.

NEWTON-UPON-AYR. See AYR, *Newton-upon*.

NEWTOWN, a parliamentary borough and market-town of Wales, Montgomeryshire, pleasantly situated in a valley on the right bank of the Severn, here crossed by a stone bridge, 8 miles S.W. of Montgomery, and 175 W.N.W. of London. The streets are narrow, and the houses have a very mean appearance, being for the most part built of lath and plaster. The parish church is a building in the early English style, with a square tower, surmounted by a wooden belfry. There are also Baptist, Independent, Wesleyan, and Calvinistic Methodist churches; a theological seminary belonging to the Independents; besides several schools, a town-hall, and a handsome cloth-hall. The manufactures of the place are considerable, and rapidly increasing in extent and importance. Flannel is the principal article produced, and with this Newtown supplies a great part of Wales. There are also tanneries, malt-houses, potteries, and iron-foundries. Newtown joins with Montgomery and other boroughs in returning a member to Parliament. Pop. (1851) of the parish, 3784; of the borough, 6371.

NEWTOWN-BARRX, a village of Ireland, in the county of Wexford, is situated at the confluence of the Clody and the Slaney, 23 miles N.N.W. of Wexford. It is in the form of an irregular square; and has a good parish church with a tower and spire, a fine Roman Catholic church, several schools, a dispensary, and a fever hospital. Manufactures of linen are carried on; and slate, granite, and limestone are quarried in the vicinity. Pop. 1437.

NEWTOWN-HAMILTON, a town of Ireland, in the county of Armagh, is situated in a valley surrounded by steep hills, 11 miles S.S.E. of Armagh. It is ill built; and has a parish church, Roman Catholic and Presbyterian churches, and several schools. Some trade is carried on in flax. Pop. 1219.

NEWTOWN-LIMAVADY, a market-town of Ireland, in the county of Londonderry, is situated on the Roe, 13 miles S.W. of Coleraine, and 15 E.N.E. of Londonderry. It has a large parish church; three Presbyterian and two Wesleyan churches; besides Independent, Roman Catholic, and Unitarian chapels; several schools; a market house; jail; dispensary; work-house; and savings-bank. The manufacture

Newton-in-
Makerfield.
||
Newtown-
Limavady.

Newtown-Stewart of linen is carried on here; and there is a considerable trade in grain and flax. Pop. (1851) 3206.

New York State. **NEWTOWN-STEWART**, a market-town of Ireland, in the county of Tyrone, 9 miles N. by W. of Omagh, contains many well-built houses; a large parish church; Presbyterian, Wesleyan, and Roman Catholic churches; a school; a dispensary; and the ruins of an old castle. Pop. 1405.

Extent and area. **NEW YORK**, one of the United States of America, is situated between Lat. 40. 30. and 45. N., and (including Long Island, &c.) between Long. 71. 51. 58., and 79. 55. It is bounded N. by Lake Ontario, St Lawrence River, and Canada East; E. by Vermont, Massachusetts, and Connecticut; S. by the Atlantic Ocean, New Jersey, and Pennsylvania; and W. by Pennsylvania, Lake Erie, and Niagara River. Its form is irregular, but may be compared to that of an irregular triangle, with its apex touching the Atlantic. The extreme length east and west of its continental part is about 335 miles, and the extreme breadth north and south about 308 miles. Including Long Island, Staten Island, &c., the total area of the state is computed at 47,000 square miles, or about one sixty-third of the entire area of the United States.

Islands. Long Island, the largest insular portion of the state, projects into the Atlantic (opposite, and in the main parallel, to the shore of the mainland, the most of which is embraced by Connecticut), a distance of about 125 miles; its greatest breadth is about 20 miles, its average breadth 12 miles, and its area about 1440 square miles. Staten Island, at the mouth of New York harbour (and included in Richmond county), is about 14 miles long, from 4 to 8 miles wide, with an area of about 60 square miles. Manhattan Island (embraced in New York city and county) has an extreme length of 13½ miles, an average breadth of 2 miles, and an area of 21½ square miles. In New York harbour are three islands—Governor's, Elles', and Bedlow's, ceded to the United States government, and fortified. In the East River, or Strait of Long Island Sound, are three islands occupied by New York city institutions. In Niagara River, about 4 miles above Niagara Falls, is Grand Island, having an area of 27½ square miles, besides several small islands.

Physical aspect. The surface of the state is considerably elevated, the larger part of it being a section of the great Alleghany table-land. There is, however, a great diversity in the aspect of the several physical divisions. The eastern half of the state is traversed by ranges of mountains; the interior has an uneven surface, and contains several large and deep lakes; and the western part, though frequently uneven, is distinguished for its broad and rich plains. There are four great natural divisions,—1. The Atlantic district,

Natural divisions. the smallest of these, comprises Long Island, which is a low sandy region, with extensive plains rising along its northern borders into hills of moderate elevation, at but one point only exceeding 300 feet in height. Its temperature differs much from that of the mainland. Its insular position, and its early settlement, have occasioned the extirpation of the larger quadrupeds; and it is more remarkable for the abundance and variety of its birds, than for the number of its mammalia. It forms the southern limit of the migrations of the arctic species of birds, and the northern limit to those of the torrid zone. It seems also to be the boundary between the fishes and other classes of the northern and tropical seas. 2. The Hudson valley district comprises the region watered by the Hudson River and its tributaries, the chief of which is the Mohawk River. The outline bears some resemblance to the letter L inverted (thus, 7), the perpendicular and main part of the letter representing the Hudson River, and the horizontal and minor part of it representing the Mohawk River. The latter, after an eastward course of 140 miles, enters the Hudson

at a distance of 160 miles from the Atlantic. This district is traversed by ranges of the Alleghany Mountains, and its western border embraces the Catskill range of mountains, some of which are nearly 4000 feet high. In regard to size, this is the third of the four districts. 3. The Northern district lies N. of the Mohawk valley, is bounded W. by Lake Ontario and the River St Lawrence, and has the shape of an irregular truncated triangle. Its south-eastern half embraces the region of the Adirondack Mountains, estimated to contain an area of about 6000 square miles, and containing numerous conical peaks and short ranges, reaching in some places an elevation of more than 5000 feet. Towards Lakes Champlain and George they subside suddenly to the level of those sheets of water. To the N. and N.W. there is a very gradual slope towards the River St Lawrence. 4. The Western district includes the region between Lakes Ontario and Erie on the N., and the Pennsylvania boundary-line on the S. A large proportion of it is elevated and furrowed by valleys, extending N. and S., which give rise to rivers pursuing opposite directions. Its central position is a level table-land, rising in its southern parts to elevations of from 1000 to 1200 feet above the sea, and abruptly subsiding on its western border to the level of Lake Erie. This same portion contains a series of lakes, stretching generally from N. to S., varying from 15 to 38 miles in length, and discharging their waters by one common outlet, the Oswego River, into Lake Ontario. Lakes Erie and Ontario exercise a great influence on the climate and other features of this district, the whole of which is exceedingly fertile, and in its uncultivated portions is covered by a vigorous growth of forest trees.

The Alleghany Mountains enter the S.E. part of the state by two distinct ridges from New Jersey and Pennsylvania. The former crosses the Hudson River at West Point, forming the highlands of the Hudson, celebrated for their scenery, which combines grandeur with the most picturesque beauty. At this crossing the highlands are from 15 to 20 miles in breadth, and have a height of about 1400 feet, and in one instance, on the E. bank of the river, near Fishkill, they attain an elevation of nearly 1700 feet. East of the Hudson this range has a N.E. direction, until it approaches near the Connecticut boundary-line, and then extends N., being called the Taconic range, until it merges in the chain of the Green Mountains. The second branch of the Alleghanies, leading from Pennsylvania, is the range of the Shawanzunk Mountains, which also extends in a N.E. direction, approaching the Hudson, but not crossing it. The Catskill range approaches the Hudson by a similar course, and extends parallel to it for 20 miles, but then bends off to the N.W., towards the Mohawk River. The mountains in the northern part of the state, which are together generally called the Adirondack Mountains, comprise several ranges which have distinct local names; but they constitute a cluster which may be considered as a branch of the great Appalachian system. In other sections there are ranges of hills and highlands.

Rivers. The most important river for purposes of general navigation exclusively within the state, is the Hudson, which is also one of the most magnificent water-courses in the New World. It rises, by two branches, among the Adirondack Mountains, and having received the Sacandaga, pursues its course (of about 160 miles from its sources) to Waterford, 10 miles above Albany, where it receives the Mohawk River, and thence flows almost directly southward about 156 miles, to its entrance through New York Bay into the Atlantic Ocean. To Troy, 151 miles from the city of New York, the tidal wave passes in from seven to nine hours from New York; and to that city the river is navigable for large steamboats of light draught. Ocean vessels do not ascend above Hudson, 118 miles from New York. The River St

New York State. Lawrence, the outlet of the great lakes, forms a large part of the northern boundary of the state, and conveys to the ocean a larger volume of water than any other river in the world, except the Amazon. It is navigable for sloops to Ogdensburg, 60 miles from Lake Ontario, but below that place its navigation is much interrupted by rapids. Several rivers of great volume, lying within the state, have each a course of above 150 miles; and, in addition to their natural service in draining and watering their respective valleys, afford, from their descent, most valuable water-power, which latter circumstance prevents continuous navigation by vessels of considerable size.

Falls and cascades.

The falls and cascades of the rivers of this state are numerous, forming notable features in its scenery. The great Falls of Niagara are elsewhere described. The Genesee River has a series of falls; near its sources it descends, within the space of two miles, by three falls of 60, 90, and 110 feet, through a wild and picturesque gorge, formed in the solid rock to the depth of 400 feet; and at Rochester it again descends by three falls of 96, 20, and 105 feet (making, with two rapids, a total descent of 268 feet within the city's limits), the first of which, by its affording immense water-power, has been a principal cause of the prosperity of that flourishing city. Fall Creek, near Ithaca, descends 438 feet, in the space of one mile, by several cascades, one of which has a perpendicular pitch of 116 feet. The Mohawk River in its falls at Cohoes is precipitated over a broken rock 62 feet high, the bank of the river forming precipitous walls 140 feet above the stream; and at Little Falls, some miles above, it passes through a fissure in the rocks, which rise on each side 500 feet above its surface. Trenton Falls is a series of cascades and rapids in West Canada Creek, a tributary of the Mohawk, and 15 miles N. of Utica, extending over 2 miles in a narrow channel cut through solid limestone rock, the sides of which in places rise perpendicularly to the height of 140 feet. At Glenn's Falls, 18 miles from Saratoga, the Hudson flows over a precipitous ledge of rocks, with a descent of 70 feet. In various other rivers, especially in the northern part of the state, there are many waterfalls of much beauty, which are also of importance from their furnishing motive power.

Lakes.

The great exterior lakes, Ontario and Erie, are navigable for the largest steamers and sailing-vessels, and each has several good harbours. Lake Champlain, between this state and Vermont, is 134 miles in length, and of comparatively narrow though unequal width, but is navigable throughout its length for steamboats of the first class. The lakes in the interior of the state not only constitute an interesting feature in its physical geography, but they are of considerable importance to commercial navigation. The largest of these which are navigable by steamers are Lake George, 36 miles long; Cayuga, 38; and Seneca, 35; after which are Oneida Lake, 20 miles long; Skaneateles, 16; Crooked, 18; Canandaigua, 15; Chautauque, 18; and several others. The northern district of the state abounds with small lakes, there being perhaps 200, some of which are greatly elevated above the sea.

Lake harbours.

The harbours of Buffalo and Dunkirk, on Lake Erie, are capacious, and are also important commercial stations, forming the termini of the two great lines of railroad which extend through the whole length of the state to the Hudson River. On Lake Ontario there are several good harbours,—viz., Sackett's Harbour, Oswego, Genesee (port of Rochester), Niagara, &c.; the first of which is the best, and was an important naval station during the war of 1812–14. Lake Champlain has some harbours, which are sufficiently commodious for the shipping on that lake.

Sea-coast.

The sea-coast of the state is nearly all comprised in the shores of Long Island, which contain a few harbours and inlets, but none that are much frequented by shipping.

The bay and harbour of New York are subsequently New York described.

New York State.

The legislature of New York, by its act of 15th April 1836, authorized a complete geological survey of the state, which should furnish a perfect and scientific account of rocks and soils, and their localities, with a list of all its mineralogical, botanical, and zoological productions, and which should also procure and preserve specimens of the same. In the execution of that act, and of the acts of May 13, 1840, and of April 9, 1842, the survey was made. The final report on the results of the survey consists of sixteen large quarto volumes, abundantly and splendidly illustrated. There are eight several collections of specimens of the animals, plants, soils, minerals, rocks, and fossils, found within the state, one of which collections constitutes a museum of natural history at the capital of the state, and the others are distributed among its collegiate institutions. A geological map is also published, and several more volumes are expected upon the palæontology. The total cost of the survey and of printing, &c., has been estimated at about £145,000.

With the exception of the alluvial and diluvial deposits, and the Geology. beds of Tertiary on the St Lawrence, occupying a very limited area, all the formations of the state of New York are older than the coal formation. The lowest rock of the coal formation occupies some small patches in the south-western part of the state; but none of the coal-bearing strata approach nearer than within six miles of the state line. The prevalence of limestone in nearly all the formations is worthy of notice, affording as it does the basis rock best adapted to yield the materials for fertilizing the soil.

There are two tracts of rocks of the Primary system (comprising Primary the unstratified crystalline and the stratified non-fossiliferous) system, which together occupy about one-third of the area of the state, and are separated from each other by the intervention of a narrow belt of sedimentary rocks. The first is in the north-eastern part of the state, and is of irregular circular form, occupying the counties of Essex, Warren, and Hamilton, with parts of the adjoining counties embraced in the region of the Adirondack Mountains. Nearly the whole of the county of Essex, with its lofty mountains, is composed of hypersthene rock, a compound of Labrador felspar and hypersthene, allied to syenitic granite. In this region it is associated with very large deposits of magnetic iron ore. Throughout this northern section primitive limestone, important for the manufacture of lime for agricultural purposes, is quite abundant. The second tract of the Primary formation consists of a comparatively small section, somewhat triangular, in the southern and south-eastern portion of the state, comprising the counties of Putnam and Westchester, with the larger part of New York, and parts of Rockland, Orange, and Dutchess. The predominant rock in both these Primary sections is gneiss, which furnishes a fine building material, and, under the popular name of granite, is extensively quarried, varying, however, in appearance and composition in different sections. Granite exists, but it is quite unimportant both in extent and value.

The term Taconic system has been given to that series (comprising Taconic seven groups, according to the New York geologists) denominated system. metamorphic, lying between the most decided crystalline slates and the lowest fossiliferous rocks. (This system, according to Professor Emmons, is fossiliferous, distinct from and lower than the New York system, and corresponds to the Cambrian rocks of Great Britain; but according to others, it is the New York system metamorphosed by heat.) The term is derived from the Taconic or Taghkanic range of the Appalachian chain, on the eastern boundary of the state, in which is the principal deposit; but there are extensive deposits of similar character all along the west side of the Green and Hoosac Mountains of New England, and so through the Appalachian ranges to Alabama, besides thinner ones in many other places throughout the United States, making in all a series of rocks many thousand feet thick and many hundred miles long. Its seven groups or formations are,—granular quartz (which furnishes white siliceous sand for glass and sand-paper, and for sawing marble), Stockbridge limestone, magnesian slate, sparry limestone, roofing slate, Taconic slate, and black slate. The limestone is fine, furnishing good building material.

The New York geologists denominate as the New York system New York that whole series of rocks which are identical with the lower and system. upper Silurian of Europe, including two or three members of the Devonian group; and this system they divide into four principal groups, and subdivide into twenty-eight minor groups. Other American geologists have given other names to these series. Our limits allow only a synopsis of their extent in the state of New York, and brief allusion to their characteristics. The four principal groups are named Champlain division, Ontario division, Helderberg series, and Erie division.

The Champlain division, the lowest of the four, corresponding to

New York
State.

the Lower Silurian (or Cambrian or graywacke) system of Europe, embraces eight formations. It occupies a very considerable but irregular territory. It extends along the St Lawrence, commencing from its mouth, to its source in Lake Ontario. A branch runs southerly along the east side of the granitic mountains of Essex, &c., along the borders of Lake Champlain, and thence south-westerly to Alabama. These rocks, indeed, flank the mountains of Essex county, &c., so as to form a huge granitic island, giving us an idea of the state of things when the Silurian rocks were in course of deposition. Its lowest formation,—viz., the Potsdam sandstone, is supposed to be the lowest fossiliferous rock in the world. The most common shell in it is a *lingula*, a genus which has survived all the revolutions of the earth, and is still found in the ocean. This formation, 300 feet thick, furnishes a beautiful and durable building material. The other formations (in ascending order), and their estimated thickness, are—calciferous sand-rock, 300 feet, in which fossils are both rare and obscure; Chazy and Black River limestones, 100 feet, some of which produce fine dark-coloured marbles, as well as good quick-lime; Trenton limestone, 400 feet, rich in organic remains; Utica slate, 100 feet, employed in roofing; and the Hudson River group, embracing the gray sandstone, 700 feet, which furnishes stone suitable for grindstones.

The Upper Silurian of Europe embraces the two highest members of the Champlain division, all the Ontario division, and more than half of the Helderberg series of the New York geologists; and its thickness is about 2400 feet. In New York the Upper Silurian rocks extend in a belt of nearly equal width along the south side of Lake Ontario (and in Canada on the north side of Lake Erie), whence it spreads out southerly and westerly over more than half of the Western States. The lowest of this system is the Oneida grit, which is 500 feet thick, coarse and fine grained, and almost destitute of organic remains. Next to this are the formations comprised in the Ontario division of the New York system,—viz., Medina sandstone, Clinton and Niagara groups, and the Onondaga Salt group. The Medina sandstone, 350 feet thick, is a red or variegated siliceous mass, sometimes marly and friable, interstratified with gray bands of quartzose sandstone. The Clinton group, 80 feet, is composed of red and variegated shales and sandstones, so diversified as to have received the name of Protean, and it abounds in fossils. The Niagara group, 264 feet, consists of shale below and limestone above. The former, exposed to atmospheric and aqueous action, crumbles away and leaves the limestone in overhanging masses, which at length break by their own weight. These are the rocks over which the water at Niagara Falls is precipitated, and this is the cause of their retrocession. This formation is highly fossiliferous. The Onondaga Salt group, from 600 to 1000 feet thick, is an immense mass of argillo-calcareous shaly rocks, abounding in veins and beds of gypsum, and the source of all the salt springs in New York and the Western States. Notwithstanding its great thickness, it is very barren in fossils. This Ontario division occupies a strip about 20 miles in width, and nearly equal in length to Lake Ontario, which bounds it on the north. The remaining varieties of the Upper Silurian (placed by Professor Hall under the name of the Lower Helderberg limestones) are—the Water Lime group, 100 feet thick; Pentamerous limestone, 80; Delthyris limestone, 200; and Upper Pentamerous limestone. The last named (with the following:—Oriskany sandstone, 700 feet thick—in Pennsylvania; Cauda Galli grit; Schoharie grit, or sandstone; Onondaga limestone; and corniferous limestone, 70) constitute the Helderberg series (of the New York system), which is most fully developed in Albany and Schoharie counties. The Helderberg limestone is cavernous; and some of its caves are celebrated for their extent, containing stalactites and stalagmites of great variety and beauty.

The formations last enumerated with the Erie division of the New York system (which consists of the following:—Marcellus slate, 50 feet thick; Hamilton group, 1000; Tully limestone, 20; Genesee slate, 250; Portage or Nunda group, 1000; Chemung group, 1500; and the Old Red sandstone, perhaps 3000—making a total thickness of about 7000 feet) constitute the Devonian system; or Old Red sandstone of Europe. The Erie division is divisible into two parts, the lower, called the Ludlowville shales, consisting of shales upon thin beds of limestone, most of them quite decomposable, occupying a belt, nearly 20 miles in width, through the central portion of the state; and the upper, called the Chemung group, consisting of thin, even beds of gray sandstone, with intervening shales, occupying the whole of the southern tier of counties. Thus it appears that in New York the Devonian system occupies the southern half of that portion of the state which extends between the Pennsylvania boundary-line on the south, and Lake Ontario and the Mohawk River on the north. The Old Red sandstone proper is confined chiefly to the Catskill Mountains, which are mainly composed of it. It consists of various strata of sandstone, shale, and shaly sandstone, the sandstones being of a red or reddish colour.

Tertiary
formation.

The clays and sands of the tertiary formation skirt the shores of

the St Lawrence, Lake Champlain, and the Hudson, consisting of a New York stiff blue clay beneath, a yellowish-brown clay in the centre, and sand above. State.

Iron ores are abundantly distributed through the north-eastern and south-eastern sections of the state, especially in the former. In Clinton and Essex counties, the deposits of magnetic iron ore, the black oxide, form beds of from 1 to 20 feet in thickness, almost without mixture, encased in granite; they are also found in the mountains of that region, and appear to extend without interruption into New York from Canada. The Stafford vein in Essex county was estimated in the geological survey to contain ore sufficient to yield three million tons of malleable iron. The specular oxide is found chiefly in the counties of St Lawrence, Jefferson, and Franklin, which border the St Lawrence River. In the south-eastern section there are extensive beds of both magnetic and hematite ores, but the latter is the more abundant. The carburet of iron occurs abundantly in the same section, and less abundantly in the north-east section. Lead ores occur in considerable deposits in various sections, of which by far the most extensive and celebrated are those in the town of Rossie, in St Lawrence county. In 1837 and 1838 these yielded nearly 3000 tons of metallic lead; but they have not been regularly worked to that extent. There are small veins of zinc, copper, &c., in several counties. The Onondaga salt springs, at and around Syracuse, are the most important in the Union; they have been worked since 1797, and the amount of their product has increased with nearly every successive year. The number of bushels of salt made in 1854 was 5,803,347; in 1855, 6,082,885; and in 1856, 5,966,810. Mineral springs, celebrated for their medicinal value, and as places of great resort in the summer, exist in various districts. The central, and some of the western counties, contain abundance of gypsum, which is largely used as a fertilizer, and extensively exported. The abundance of excellent building material has already been noticed. The petroleum springs, in the counties of Cattaraugus and Alleghany; the nitrogen springs of New Lebanon and Hoosac; and the carburetted hydrogen springs, in the neighbourhood of Lake Erie and Niagara River, are also worthy of notice. There are several springs of the last-named class in the county of Chautauque, one of which affords gas that is used to light the houses in the village of Fredonia, while another supplies the lighthouse in the village of Barcelona.

The soils of this state are so very various, that a full and correct description of them, within our limits, is impossible. In general terms, the most of the soils, or the greater portion of the surface of the state, may properly be called very fertile. The sections least fertile are in the north-east part, traversed by the mountains, where much of the surface is poor and cold; and yet there are many productive valleys in that region. The valleys of the Hudson and Mohawk comprise tracts of excellent soil, but they are greatly surpassed in extent and fertility by the western parts of the state, especially by the section known as the Genesee Flats.

The different sections of the state have considerable diversities of climate, each being marked by its own peculiarities. Taken altogether, the climate of the state is everywhere one of great extremes, and subject to sudden and severe changes at all times of the year. Notwithstanding this, however, it appears that the state as a whole is very healthy. The mean average temperature of the whole state is 46° 49 Fahr.; mean maximum 92°, mean minimum 12° below zero, and the mean annual range 104°. The southern section of the valley of the Hudson, and the whole of Long Island, are the most equable portions of the state. The Mohawk valley has a climate which does not vary greatly from the mean average. The region N. and E. of the Mohawk is characterized by a low average tem-

New York
State.

perature, backward seasons, and early frosts. The western or lake region has a similar climate to that of Long Island. Summarily, this state has the summer heats of Spain and Italy, and the rigour of its winter is equal to those of the northern portions of Europe.

Vegeta-
tion.

Corresponding to the varieties in its characteristics of surface, soil, and climate, we find, as we should expect, that this state has an exceedingly diverse vegetation. Within its borders are trees, shrubs, grasses, &c., of both extremes of the States—the north and the south. Its most important natural growth is that of its forest trees, which once covered its whole territory, and yet occupy the immense tracts that have not been brought under cultivation. The most common trees in the forest are the varieties of oak, pine, beech, &c.; but scarcely any variety, found under similar latitude and climate, is wanting. The mountain sides and woods are clothed with a shrubby undergrowth. The native grasses are numerous and widely distributed, but only a few of them are valuable, and the cultivated meadow grasses are of foreign origin. The whole number of flowering plants in the state is about 1450,—of which 1200 are herbaceous, and 150 may be regarded as ornamental. Of woody plants, there are 250 species, including 80 that attain to the stature of trees. Of plants that are reputed medicinal there are, native and naturalized, about 160 species.

Zoology.

From the diversity of the climate, which exercises a great influence upon the number and distribution of its animals, it results that its classes of the animal kingdom comprise those found in both the northern and southern portions of Europe. The families *Cervidae* and *Mustelidae* may serve as examples of the one; while the *Vespertilionidae* and *Muridae* will illustrate the other. The previous explanation of the natural divisions of the state points out the four principal zoological districts, each sufficiently distinct in itself, but of course so much blended at the lines of separation as not to be contradistinguished. The forests were formerly ranged by the moose, stag, and reindeer, but these are now seldom met with. The existing animals are the American deer, black bear, puma, &c., descending in size to the hares, squirrels, and smaller quadrupeds. The Mastodon has been found in a fossil state in several places; the most perfect and gigantic skeleton being that found in 1845 near Newburgh, Orange county, weighing 2000 lbs., and owned by Dr John C. Warren of Boston, by whom it has been described in one of the memoirs published by the Smithsonian Institution. Teeth and other remains of elephants, &c., have been occasionally dug up. Of birds of prey the species are numerous; of birds of passage, 20 different tribes and 149 species; of the Scansoriae, the genus *Picus* (woodpecker) is very common; of the Gallinaceæ, several species; of the Grallatoria, or waders, there are 62 species in 7 families; and of the Palmipedes, or swimming birds, there are many varieties. In regard to the Reptilia, Amphibia, Pisces, Mollusca, Crustacea, and Insecta, we have not room for even a condensation of the results of the survey of the state.

The aborig-
ines and
their anti-
quities.

The state of New York, in common with other portions of North America, possesses many interesting but obscure traces of once powerful nations, which seem to have existed previous to those savage tribes who occupied the country at the period of its discovery by Europeans. The ruins of fortifications, mounds, &c., the traces of agriculture, and the remains of rude art which have been brought to light in various parts of the state, display marks of high antiquity, and bespeak the existence of a people entirely distinct from the Indians who were found here by the first European discoverers. These works consist chiefly of earthen parapets, the sites of which, with a view to defence, appear to have been selected with much judgment; and greater skill was exercised in their construction than has been displayed by the Indian races known to us. The forms of these

remains are various, being circular, elliptical, triangular, and square; and they are generally placed in situations which command the adjacent country. Near many of the forts are mounds of earth raised for cemeteries, in which human bones, in various stages of decay, are common. These may have been the burial places, in some instances, of the more recent Indian tribes. The number of forts and mounds in the western part of the state much exceeds 100. The inclosed areas of the fortifications vary from 6 acres to 100 feet in diameter; and the earthen walls which inclose them, in their present abraded condition, are from 10 to 12 feet in height, and from 6 to 8 feet in breadth. Some of these breastworks bear or have borne trees, whose age has been estimated at more than two hundred and seventy-five years, and which may have been preceded by others. There are indications that the architects of these works were not so greatly advanced in civilization as the Toltecs or Aztecs of Mexico, and thus their origin is surrounded with additional mystery.

At the time of the first settlement of New York, the principal Indian tribes in the region now comprised in the state were those of the celebrated confederacy of the Five Nations, viz., the Mohawk, Oneida, Seneca, Onondaga, and Cayuga. It is asserted by a writer in 1741, that this confederacy was established, as the Indians say, one age or one man's life before the white people settled at Albany (1615), or before white men came to the country. Long before they were known to the Europeans, these nations had acquired a decided superiority over other Indians; and this they long retained, extending their conquests as far as South Carolina. In 1714 they were joined by the Tuscaroras, and from that time the confederation was known as that of the Six Nations. In 1608 Champlain, by his attack, had rendered them hostile to the French, and their hostility continued until the French lost Canada. Their alliance with the English continued so firm, that on the breaking out of (and in fact before) the Revolutionary war, they were induced to engage against the Americans. The Six Nations then numbered about 10,000, and had 2000 bold and skilful warriors. Including these, there were, within the Indian department of the northern provinces, 130,000 Indians, of whom 25,420 were fighting men. But if their employment by the British government was disastrous to the Americans, it was equally so to the Indians. A considerable portion of the Oneidas refused to join with the other tribes against the colonists. The bond of this confederacy was severed never to be reunited. The war made sad havoc with their warriors, and at its close the remnants of the tribes passed away before the influx of settlers. In 1788 and 1789 the Six Nations, by treaty, conveyed to the state a large tract of their territory; and by other purchases, &c., the Indian title to nearly all lands in the state was extinguished. Certain reservations, chiefly in the western counties, were made, portions of which the Indians and their descendants have continued to hold to the present time. Their total number in 1845 was 3753; in 1855, 3934.

The history of New York commences with 1609. On the third day of September in that year, Henry Hudson, an Englishman by birth, in the service of the Dutch East India Company, anchored his vessel, the *Crescent*, within Sandy Hook. Almost at the same time Champlain was invading New York from the north. After a week's delay, Hudson sailed (Sept. 11) through the Narrows, and anchored in New York harbour. Ten days (Sept. 12th to 22d) were employed in exploring the river. Hudson, the first of Europeans who penetrated so far into the country, went sounding his way beyond the Highlands, till the *Crescent* had sailed some miles above the city of Hudson, and a boat had advanced a little beyond Albany. Frequent intercourse was held with the astonished Indians. Having completed his discovery, Hudson descended the

New York
State.

New York State. stream to which time has given his name; and, on the fourth day of October, set sail for Europe.

Early Dutch traffic.

The right of possession of the country was claimed for the United Provinces; and, in 1610, merchants of Amsterdam fitted out a ship with various merchandise to traffic with the natives. The voyage was prosperous, and was renewed. In 1614 the first rude fort was erected—probably on the southern point of Manhattan Island. In the next year (1615) the settlement at Albany was begun, on an island just below the present city. This was the remote port of the Indian trader, and was never again abandoned. Yet at this early period there was no colony; not a single family had emigrated; the only Europeans on the Hudson were commercial agents and their subordinates. The Dutch West India Company was incorporated, June 3, 1621, for twenty-four years, and became the sovereign of the central portion of the United States, though colonization on the Hudson was neither the motive nor main object in its establishment. Its first ship arrived in the harbour of New York in 1623. This is the era of the permanent settlement of the country, which in its development shortly assumed the form of a colony.

Colonial history.

In 1624 Peter Minuits, the commercial agent of the West India Company, arrived with several families, and thenceforward held the office of director (governor) until 1633, when he was succeeded by Wouter Van Twiller, who in 1638 gave place to William Kieft. During the administration of the latter, the colony was troubled by controversies with the encroaching English, and suffered from the provoked hostilities of the Indians. In 1647 Peter Stuyvesant became governor, and by his exertions a provisional treaty was made with the surrounding English colonies. In 1664 Charles II. granted to his brother James, the Duke of York, the territory claimed by the Dutch. On 8th September of that year, Colonel Nichols, commissioned for the purpose, compelled Stuyvesant to surrender, and changed the name of New Netherlands to New York. In 1673 the Dutch retook the colony, but in the next year they finally surrendered it to the English, who held possession until the American Revolution. During this lengthy period New York suffered much from the Indian depredations and ravages in the wars waged between the French and English. In 1690 Schenectady was burned by the savages, and many of its inhabitants massacred. Apart from these wars, no very important event occurred for many years preceding the negro plot in 1741. On 7th October 1765, the first continental congress of the colonies met in New York city; and from that time, until the close of the Revolution, the general history of New York is almost identical with that of the united colonies.

Events of the Revolution in New York.

A considerable portion of the active hostilities of the revolutionary war took place on the soil of this state. At its commencement the American militia captured Ticonderoga, Crown Point, and Whitehall, and thus secured the command of Lake Champlain. The most prominent occurrences in New York were,—the defeat, in the autumn of 1776, of the Americans on Long Island and at White Plains; the surrender, on 17th October 1777, of Burgoyne, the British general, with his 6000 troops; and the capture, on the 16th July 1779 of Stony Point by the Americans, under General Wayne. Jay, Hamilton, and others distinguished in the national councils, were natives of New York.

Formation of State government.

The colonial government was suspended in May 1775, from which time, to 20th April 1777, a provincial congress governed; of which Nathaniel Woodhull was president from August 1775. On 9th July 1776, the fourth session of this body met, by adjournment, at White Plains, and having received the Declaration of Independence, approved it. On 12th March 1777, a constitution for the

state was reported by a committee of the congress; on New York the 20th April following it was adopted; and it so remained State. through the war, and afterwards. On 26th July 1788 it was ratified by the state legislature, and it thence continued to be the organic law, without change (excepting a few amendments in 1801) until 1821, when it was revised by a convention elected for that purpose; and their revision was duly ratified by the people. In 1846 a new constitution, prepared by a convention, was approved by the people; and to this was made, in 1854, an amendment relative to the public debt.

The present constitution came into operation 1st Jan- Govern- uary 1847. The right to vote is granted to every white ment. male adult citizen resident of the state one year, of the Abstract county four months, and of the election district thirty of the Con- days; and to coloured persons having paid tax on freehold stitution. estate of L.52, and been citizens for three years. General elections are held on the Tuesday after first Monday in November. The legislature assembles on the first Tuesday in January. Senators (32) are elected for two years; assembly-men (128) for one year; and both receive 12s. 6d. per diem for a hundred days' session, with mileage. The Judiciary is thus constituted:—The court for the trial of impeachments consists of the senate and the judges of the court of appeals, and its judgment extends only to removal or disqualification for office, with liability to indictment. The court of appeals is composed of 8 judges, of whom 4 are elected by the electors of the state, and 4 are selected from the justices of the supreme court having the shortest time to serve, and its chief judge is chosen from those elected. The supreme court, having general jurisdiction in law and equity, comprises 8 districts, in each of which 4 justices are elected for eight years. County courts (except New York county) consist of 1 judge, elected for four years. Municipal courts have uniform organization and jurisdiction; justices of the peace are elected for four years. Any male adult citizen of good morals, and requisite ability, may practice in all state courts. The governor, elected by the people for two years, must be thirty years old, state resident for five years, and United States citizen. Of the administrative officers, the secretary of state, comptroller, treasurer, attorney-general, and state engineer, are elected by the people for two years.

In 1814 the state had a fund applicable to the support Finances. of its government, amounting to L.916,017. In 1817 the construction of the Erie and Champlain canals was commenced; and in defraying their cost the public monies were exhausted, and a debt was created. Before the year 1835 the state had formed 656 miles of canal, at a cost of L.2,427,631, of which the Erie Canal, 364 miles long, cost L.1,488,285. The public debt, though it has been gradually increasing, has never been a burden to the taxpayers of the state; since the receipts from the tolls, &c., of the canals, have not only paid the expenses of the canals and a large share of the ordinary expenses of government, but have earned a surplus, used in discharging the interest of the debt. On 30th September 1856, the total canal debt was L.4,670,056. The work of enlarging the canals, which, for several years, has been in progress, has resulted in an increase of the canal debt; but, it is confidently believed, that when this is completed, the canals will amply repay all the cost of construction and maintenance, and thereafter, afford a large revenue to the state. In 1856 the assessed value of taxable property in the state was nearly L.292,000,000; but this assessment, as in all the states, is much below the real value.

The following table exhibits the result of the census Popula- of New York during the period preceding the War of tion. Independence:—

New York
State.

Years.	Whites.		Blacks.		Total Population.
	Male.	Female.	Male.	Female.	
1698	8,143	7,754	2170		18,067
1703	9,322	9,085	1,174	1084	20,665
1723	17,583	16,810	3,364	2807	40,564
1731	24,856	18,205	4,866	2897	50,824
1737	25,740	25,756	4,948	3993	60,437
1746	26,860	25,622	4,857	4250	61,589
1749	32,355	30,401	5,696	4896	73,348
1756	43,261	39,981	7,570	5978	96,790
1771	73,990	69,484	10,623	9240	163,337

In 1774 it was estimated that the colony of New York embraced a population of 161,098 whites, and 21,149 blacks; or 182,247 in all. Of the enumerations in 1776 and 1782, only fragments now remain. In 1786 a full census gave to the state a total of 238,897; of which there were 219,956 whites, 18,889 slaves, and 12 Indians paying taxes. The following table is a synopsis of the enumerations of the state from 1790 to 1850, taken by United States' authority:—

Date of Census.	White Persons.	Coloured persons.			Total Population.
		Free.	Slave.	Total.	
1790	314,142	4,654	21,324	25,978	340,120
1800	556,039	10,374	20,343	30,717	586,756
1810	918,699	25,333	15,017	40,350	959,049
1820	1,332,744	29,980	10,088	40,068	1,372,812
1830	1,873,663	44,870	75	44,945	1,918,608
1840	2,378,890	50,027	4	50,031	2,428,921
1850	3,048,325	49,069	0	49,069	3,097,394

The increase of population in this state during these sixty years was not only greater in absolute numbers, but was also greater in proportion than in any other of the free states, the ratio having been 810·68 per cent.; while Maine, which exhibited the next greatest growth, increased its population 504·07 per cent. during the same period. On 1st June 1855, the population had increased to 3,466,212; of which there were 45,286 coloured persons.

Origin of
population.

The state census of 1845 first directed inquiries concerning place of birth, which were of a general character. Similar, but more minute inquiries, were made in the national census of 1850, and still more careful investigations in the state census of 1855. A synopsis of the returns of the three periods thus presented:—

Place of birth.	1845.	1850. ¹	1850. ¹	1855.
State of New York.....	1,894,278	2,129,551	2,151,196	2,222,321
New England States (6)	228,881	307,120	206,630	207,539
Other United States.....	83,642		81,470	98,584
Total United States....	2,206,801	2,436,771	2,439,296	2,528,444
Foreign countries.....	347,266	655,929	651,801	920,019
At sea.....	511
Unknown	50,428	4,694	6,297	17,238
Total	2,604,495	3,097,394	3,097,394	3,466,212

¹ The two tables for 1850 are both derived from the official United States census. Their discrepancies are owing to the circumstance that the tables from which these totals were taken were prepared for different purposes, in different ways, and at different times, involving the examination of the names of many millions of persons, and easily giving opportunity for some errors. The first is perhaps the more correct. It is taken from Tables XL. and XLVII. of the *Compendium*, 8vo, and is composed thus:—

Nativities.	Whites.	Free Coloured.	Total.
Born in the State.....	2,092,076	37,575	2,129,651
Born out of the State, and in the United States.....	296,754	10,366	307,120
Born in foreign countries.....	655,224	705	655,929
Unknown.....	4,271	423	4,694
Aggregate.....	3,048,325	49,039	3,097,394

Percentage of classes:—

	1845.	1850.	1850.	1855.	New York State.
United States.....	84·731	78·672	78·753	72·903	Migrations.
Foreign countries.....	13·333	21·177	21·043	26·585	
Unknown	1·935	·151	·203	0·512	

The published results of the census of 1850 and 1855 confirm the well-known fact that the Americans are migratory in their character, and that the tendency of their migration is westward. In 1850 the number of persons born in this state, but then residing in other states, was 547,218; and the number of those born in other states, but then residing in this state, was 288,100; showing an excess of 259,119 given to other states. The census of 1855 plainly shows that a very large proportion of the inhabitants of the western counties were born in the eastern counties.

The following table shows the respective numbers of the population, on the 1st June 1855, born in foreign countries (having over 100 emigrants in the state), and the percentage of the same in the total population:—

Countries.	Number.	Per cent.	Countries.	Number.	Per cent.
Ireland.....	469,753	13·549	Sweden	1,472	0·042
Germany.....	218,997	6·314	Italy.....	1,231	0·036
England	102,286	2·949	Austria.....	1,147	0·034
Canada	47,842	1·379	New Brunswick....	766	0·022
Scotland.....	27,523	0·794	Denmark.....	583	0·017
France.....	18,366	0·529	Spain.....	570	0·017
Wales.....	8,557	0·246	Norway.....	537	0·016

Nova Scotia.....	1,602	0·046	Mexico.....	119	0·003

In 1821, by a provision of the state constitution as then revised and adopted, the elective franchise was extended to all white male citizens, of the age of twenty-one years, who paid taxes or performed military duty, or who were by law exempt from taxes or military service. In 1826 the constitution was amended by entirely abolishing the property qualification of white voters by a popular vote of 127,077 for, to 3215 against it. Since 1821 the state census period has been decennial, commencing with 1825. Its successive returns of the total population, and of the number of voters and aliens, have been as follows:—

Years.	Total Population.	Total number of		Percentage of Pop.	
		Voters.	Aliens.	Voters.	Aliens.
1825	1,616,458	296,132	40,430	18·32	2·50
1835	2,174,517	422,034	82,319	19·41	3·79
1845	2,604,495	539,379	153,717	20·32	5·89
1855	3,466,212	652,322	632,746	18·01	18·54

The constitution of 1821 provided that no man of colour should vote unless possessed of a freehold worth L.52, above all incumbrances, and for three years a citizen, &c.; also, that no person of colour should be taxed unless possessed of said real estate. In the adoption of the constitution of 1846, this provision was retained by a special vote of

New York State. 114,900 for, to 3901 against retaining it. The returns of this class have been as follows:—

Coloured persons.	1825.	1835.	1845.	1855.
Not taxed.....	38,770	42,836	42,321	35,956
Taxed.....	931	934	2,025	9,330
Voters.....	298	578	1,061	...

Growth of the cities.

One of the most prominent indications of the recent enumerations is the tendency of the population to centralize in cities and large towns, and apparently at the expense of the rural districts. These changes, however, inevitably result from the greater changes in the general condition of the state and the whole Union. The increase of the facilities of intercommunication has concentrated the trades that they may take advantage of the division of labour. The unlimited field of enterprise offered in manufactures, trade, and commerce, has caused a remarkable growth of cities and towns along the lines and at the centres of the great routes of transportation and travel; and these localities have also received the greater share of the foreign immigration. In 1855 the eight chief cities contained nearly one-third of the whole population of the state. The following table shows their growth:—

Cities.	1830.	1835.	1840.	1845.	1850.	1855.
New York...	197,112	268,089	312,710	371,223	515,547	629,810
Brooklyn	17,014	27,854	42,622	72,769	131,357	205,250
Buffalo.....	8,668	19,715	18,213	29,773	42,261	74,214
Albany.....	24,209	28,109	33,721	42,139	50,763	57,333
Rochester....	9,207	14,404	20,191	26,965	36,403	43,877
Troy.....	11,556	16,959	19,334	21,709	28,785	33,269
Syracuse	(Incorporated as a city in 1843.)				22,271	25,107
Utica.....	8,323	10,183	12,782	12,190	17,565	22,169

In 1855 there were twenty-eight townships, with an aggregate population ranging from 5000 to 14,000, which contained one or more flourishing villages; and fifty-four other townships, with a population ranging from 4000 to 6500, with villages, &c.

The rural districts.

In the western and other agricultural sections of the state, the increase of population has been checked by the extensive emigration therefrom to the western states and territories. This emigration has drawn off a considerable share of the best class of the native population. However, it should be considered that, in many sections, agriculture itself requires less manual labour than formerly. The well provided farmer of the present day has his machines for sowing, hoeing, reaping, and threshing, and other improved implements of agriculture.

Occupations of the people.

The employments of the male population over fifteen years of age were thus summed up in the census of 1850:—

Occupations of the People.	Numbers.
Agriculture	313,980
Manufactures, mechanic arts, mining, trade, and commerce	312,697
Labour not agricultural.....	196,613
Sea and river navigation.....	23,243
Law, medicine, and divinity	14,258
Other pursuits requiring education.....	11,104
Government civil service	4,985
Army.....	1,462
Domestic servants	6,324
Other occupations	3,628
Total.....	888,294

Owing to the absence of uniformity in the schedules on this subject in the several enumerations, there are no reliable data for comparing the number of persons in the various occupations at different periods.

Productive industry.

New York stands unrivalled among the states of the

Union in most of the great branches of national industry. In some few particulars it is surpassed by some states, which have greater natural advantages for the prosecution of those branches,—as Maine, in making lumber and building vessels; Pennsylvania, in raising coal and producing iron; and Massachusetts, in manufacturing cotton and woollen goods, and in prosecuting the coast fisheries. But, taken altogether, the industrial pursuits in New York are more varied and more valuable in their results than those of any other state.

Agriculture employs the greater part of the population, Agriculture exclusive of the inhabitants of the cities and large villages.

Great efforts have been made, especially by agricultural societies, to introduce everywhere the best modes of culture, and with much success. Improvements of this class have been particularly made in the vicinity of the city of New York; although in that section this result has been directly owing to the great demands of the populous city. For example, the western part of Long Island has soil that is naturally of moderate fertility; but it has been greatly improved, and it is now noted for its market produce.

Comparison of some of the Returns in 1850 and 1855.

In State of New York.	1850.	1855.
Number of farms, &c.	170,621	231,740
Acres of improved land	12,408,964	13,657,491
Acres of unimproved land	6,710,120 ¹	13,100,693
Cash value of farms.....	L.115,530,545	L.166,532,362
Cash value of implements	4,601,021	5,609,892
Cash value of stock.....	15,327,183	21,620,007

In 1850, average number of acres in the farms, 113; average value of same, L.675; average value of farming implements and machinery, L.25. According to the census of 1850 (in which the returns of products are for the year ending 1st June 1850) New York ranked as first of the states in its aggregate production of oats (26,552,814 bush. out of 146,584,179 in the whole Union), of buckwheat (3,183,955 out of 8,956,812), of barley (3,585,059 out of 5,167,015), of Irish potatoes (15,398,368 out of 65,797,896), of peas and beans, of market garden products, of orchard products, and of hay, maple, sugar, honey, and hops. The wheat crop was 13,121,498 bush., or 13 per cent. of the whole United States' crop, and ranking as the third state in this respect; that of Indian corn was larger, amounting to 17,858,400 bush., though only 3 per cent. of the United States' crop. It also ranked as first of the states in the amount of its live stock (valued at L.15,325,099 out of L.113,370,936 in the whole Union), in the value of animals slaughtered, and in its products of butter and cheese. Its product of wool was about one-fifth of all in the Union, greatly exceeding that of every other state, excepting Ohio, which was a trifle larger.

In manufactures New York is very extensively engaged. Manufactures. Its aggregate productions of this class of industry in 1850 tures. not only exceeded the corresponding product of any other state, but amounted to nearly one-fourth of all manufactures produced in the United States.

Statement of Establishments in 1850, each producing to the amount of L.104, or upwards, yearly.

Classes.	No.	Capital.	Value of Raw Material.	Persons Employed.	Annual Product.
Cotton	86	L.870,189	L.413,740	6,320	L.748,326
Woollen	249	929,032	799,618	6,674	1,464,706
Pig iron.....	18	126,040	66,373	505	124,564
Iron-casting.....	323	963,013	499,738	5,925	1,233,742
Wrought iron	81	389,924	480,297	2,130	788,068
Distilling, &c.....	189	539,728	...	1,676	...
Tanning.....	942	1,046,901	1,268,584	4,945	204,298
Salt.....	192	170,820	131,654	573	207,979
Total	23,553	L.20,513,414	L.28,053,260	199,349	L.49,499,421

Per cent. profit of the total, 53.86; total females employed

¹ This return of unimproved land is of that attached to farms.

New York
State.

(included in the above) 51,612—in cotton works 3668, woollen 2412, tanning 31; total annual wages of all persons employed L.8,360,623. From the census of 1850 it appears that of the classes of manufactures specifically mentioned New York then ranked as first of the states only in the manufactures of iron-casting, those of tanneries, and of salt, beer, and ardent spirits; indicating that its products, aside from the great classes, were of many kinds. It also appears that, in distilleries and breweries, New York employed more capital than any other state (amounting to L.538,726 out of L.1,772,409 in the whole Union); that its product of beer was about four-sevenths, of rum about two-fifths, and of whisky and high wines about two-ninths of all made in the Union. The census of 1855 returned the following statements:—

Total number of establishments	24,833
Establishments using water-power	7,551
Establishments using steam-power	2,444
Persons	
Men	155,159
Women	37,771
Employed.	
Boys under 18 years	15,736
Girls under 18 years	6,233
Capital invested in real estate	L.14,818,832
Capital invested in tools and machinery	7,337,406
Cash value of raw materials used	37,165,478
Cash value of manufactured articles	66,128,815

Mining.

The products from mining, so far as reported in 1850, are included in the preceding total of the manufactures. The localities in which this branch of industry is prosecuted are referred to in the previous descriptions of the geology and mineralogy of the state. The census of 1840 reported that 1898 persons were then employed in mining.

Lumber
business.

The lumber business of this state is a source of much wealth. The forests about the Sasquehanna and Delaware furnish large quantities of pine for the Philadelphia and Baltimore markets. Albany is noted as one of the greatest markets for lumber in the world, though the greater part of it is not obtained from New York, but from Canada, Michigan, and Ohio.

Fisheries.

The interest of New York in the coast fisheries is important, but there are no official or reliable returns on this subject. In the deep-sea fisheries the state is not largely engaged, and less so now than formerly. The number of vessels in the whale fishery, January 1, 1856, was 31, with aggregate tonnage of 10,493 tons, showing a great decrease from former times.

Building of
vessels.

The building of vessels is very extensively prosecuted. The amount of tonnage built within this state annually, during the last four years, has uniformly averaged one-fifth of the whole built in the Union. Nearly all of the great American steam-ships have been built in New York city.

Tonnage
owned in
New York.

The amount of tonnage owned in this state is proportionably less than the commerce, because many vessels which are employed in its carrying-trade are built, owned, and registered, or enrolled in other states. New York, however, owns two-sevenths of the total tonnage, and one-third of the steam tonnage of the whole United States.

Statement of 30th June 1856.

	New York.	United States.
Total tonnage	1,508,810	4,871,652
Registered steam tonnage	68,777	89,715
Enrolled steam tonnage	155,738	583,362
Total steam tonnage	224,515	673,077

Tonnage of the several Districts in 1856.

New York	1,328,036	Cape Vincent	6,130
Sag Harbour	7,219	Sackett's Harbour	1,571
Greenport	10,238	Oswego	38,888
Cold Spring	1,393	Genesee	4,012
Champlain	11,249	Niagara	566
Oswegatchie	9,572	Buffalo Creek	89,929
Total tonnage owned in the state, 1,508,810; consisting of 734,283 enrolled and licensed, and 774,526 registered.			

The internal improvements of New York are remarkable for their extent and cost, and have most beneficially influenced the prosperity of the state and of the Union. Most of the canals were constructed, and are now owned by the state, and these have an aggregate length of about 800 miles. All the railroads have been formed by incorporated companies, and without the aid of the state, excepting its subscription of L.625,000 to the New York and Erie Railroad. In the interior, especially in the vicinity of large towns, there are many excellent plank-roads, which have probably cost, in the aggregate, at least L.1,000,000. The state's receipts from the canals have of late years varied between L.540,000 and L.625,000 annually; and about one-third of this is expended for the care, repairs, &c., of the canals. The Erie Canal was constructed during 1817-25, 364 miles long and 40 feet wide, at a cost of L.1,488,286; at various periods sections of it have been enlarged, and this work of improvement is still in progress. The Delaware and Hudson Canal was built, and is owned by an incorporated company; 83 miles of its length is within New York. In 1832 the first two lines of railroad were opened,—viz., from Albany to Schenectady 15 miles, and from the latter place to Saratoga Springs. Statistics (September 30, 1855) of railroads in New York:—Length of track laid, 2611½ miles; length of double track, including sidings, 912½ miles; total cost of road, equipment, and other expenditures, L.26,851,679; total amount of funded and floating debt, L.16,276,209; capital stock paid in, L.14,404,560; gross receipts in fiscal year 1855, L.4,492,224; do. expenses, L.2,520,448. Length of main line of Erie Railroad,—New York city to Dunkirk, 461 miles; New York Central Railroad, Albany to Buffalo, 298 miles; Hudson River Railroad, New York to Albany, 144 miles.

The total amount of the domestic and coasting trade of this state is not known with any exactness; but this, undoubtedly, is in a ratio corresponding to the extent of its canals and railroads, and the amount of its foreign commerce, as compared with other states.

The foreign commerce of New York comprises about two-fifths of the exports of all the United States, and somewhat more than three-fifths of the imports,—thus averaging more than half the foreign commerce of the nation.

The following table is made up from the returns of the collection districts for fiscal year 1856:—

Collection Districts.	Exports.		Imports.
	Domestic.	Foreign.	Total.
New York	L.20,573,660	L.1,270,538	L.40,759,478
Champlain	490,578	242,499	358,000
Oswegatchie	161,374	154,095	376,832
Cape Vincent	138,718	62,218	330,691
Sackett's Harbour ..	169	...	3,770
Oswego	997,445	142,987	1,108,595
Genesee	157,896	...	232,787
Niagara	182,266	40,562	219,943
Buffalo Creek	180,967	16,845	393,171
Total in 1852 ...	15,425,535	2,800,387	27,568,600
Total in 1854 ...	21,989,942	3,538,101	40,714,148
Total in 1856 ...	22,885,102	1,929,785	43,783,425

Soon after the organization of the state government, provision was made for an efficient system of public education. Every town is divided into a suitable number of districts, and in each is a school maintained at the public expense. Statistics of the year 1855:—

School districts in which school was kept on an average eight months in the year, reported	11,883
Teachers employed (males 10,117; females 14,019), do.	24,136
Children in state between 4 and 21 years, do.	1,207,214
Attendance in the common schools, do.	876,603
Attendance in private unincorporated schools, do.	45,362
Attendance in academies, do.	29,967

New York State. Aggregate attendance, as above 951,932
Aggregate expenditures for common schools L.735,817

It may be justly concluded that there is comparatively only a small proportion of the children and youth in the state who do not spend a portion of their time in school.

State Funds for Education.	Capital.	Income 1856.
Common school fund	L.519,146	L.32,736
Literature fund	56,132	3,536
United States deposit fund.....	836,357	53,519

Eighteen collegiate institutions, in the census of 1850, were reported to have 174 teachers, 2673 pupils, and an annual income of L.30,864; and 883 academies, &c., were reported to have 3130 teachers, 49,262 pupils, and annual income of L.168,817.

Public libraries.

Libraries other than private in the State in 1850.

Libraries.	Number.	Volumes.
Public	43	197,229
School	10,802	1,388,729

In 1855, number whose circulation was reported... 540
Copies printed per annum of those reported.....193,294,621
Estimated copies per annum of all classes.....241,749,902

Churches.

The following table presents the statistics of the principal religious denominations, according to the census of 1855, preceded by the total, which embraces over forty sects. These returns are of those religious societies that have each a regular chapel of their own, not including those that worship in schoolhouses and places of secular use:—

Denominations.	Chapels.	Value of Property.	Usual Attendance.	Church Members.
Baptists, four sects.....	882	L. 658,233	143,465	89,713
Congregational.....	301	300,873	56,637	25,946
Evangelical Lutheran....	100	81,281	20,834	13,964

Average value of churches, L.1290; average accommodation, 421; average number of inhabitants to each church, 683. Percentage of accommodation to total population, 61.73; of attendance do., 32.41; of membership do., 20.23.

Pauperism, &c. By census of 1825 the percentage of paupers to total population was 0.34; do. 1835, 0.31; do. 1845, 0.32. The census of 1855 made no report on this subject. It is known, however, by the annual reports of the secretary of state, that pauperism has, since 1845, been much increased,

though in no greater ratio than the foreign immigration, to New York City.

During the year 1855 there were convicted in the courts of record of the state 1842 persons, as follows:—Of Crime. offences against the person, 397 (383 males and 14 females); offences against property with violence, 278 (275 males and 3 females); offences without violence, 586 (507 males and 79 females); offences against the currency, 37 (36 males and 1 female); all other offences, 544 (513 males and 31 females). In all the courts there were 6744 convictions, and of these 5076 were of foreigners.

There are three state prisons, in which for the 8 years State 1847–55, the average yearly number of prisoners was about 1700; and the average yearly increase was 86. Number on 1st December 1855, 1901 (1679 whites and 222 blacks); and of these 92 were white females, and 14 black females.

The state has two establishments for the reformation of Houses of juvenile offenders. The older one, at Randall's Island, city refuge. of New York, was opened in 1825; and, up to the close of 1856, had received 6880 children and youth, of whom it is believed that 70 per cent. were there reformed.

The state maintains numerous public institutions for Public in those unfortunate by nature or calamity. These are very stitutions. extensive, and conducted according to the best practice known in similar establishments. The chief of these are —the lunatic asylum at Utica; institution for the deaf-and-dumb at New York; institution for the blind at New York; and the asylum for idiots at Syracuse. At New York also, partly sustained by the state, are the City Hospital, Bloomingdale Asylum for the insane; emigrant hospitals; institutions for seamen; dispensaries, &c. (F. H.)

NEW YORK, city and port of entry, New York county, state of New York, lies at the head of New York Bay, and at the confluence of the Hudson River and the strait called East River, which connects Long Island Sound through New York Bay with the Atlantic Ocean. It is the commercial metropolis of the state of New York, and the greatest emporium in the New World. In general importance it surpasses all other great cities of the world, excepting London and Paris. Its area comprises (the city and county having the same limits) the whole of Manhattan or New York Island, and several small islands immediately adjacent. The separation of the former from the mainland is caused by the water-course called Harlem River, connecting the Hudson and East Rivers; but this is, in fact, of little account; for, although the stream is, or might be, of considerable service in navigation, it is crossed by bridges, and the Croton Aqueduct. The extreme length of New York Island is about 13½ miles; its width through the greater part of its length is about 2 miles; but at each extremity it decreases irregularly; and its area is about 14,000 acres, or 22 square miles. Lat. of the City Hall 40. 42. 43. N., Long. of do. from Greenwich 74. 0. 3. W.

New York enjoys from nature almost every advantage Harbour, that could be desired to build up a great emporium. It bay, and extends between two rivers, each of which is navigable for rivers. the largest vessels; and the harbour, below their confluence, might contain the navies of all nations. The width of the Hudson River is quite uniform, and is somewhat more than a mile; while that of the East River varies, being, in some narrow localities, not more than two-fifths of a mile, though generally much greater. The harbour or inner bay is of irregular elliptical form, about 8 miles long and 25 miles in periphery. This is not only one of the best but one of the most beautiful harbours in the world. Its southern part is surrounded with small settlements, connected by elegant villas and their gardens. Toward its northern part the number of vessels at anchor increases; and beyond these is the dense forest of masts, bearing the flags of all nations, crowded around the wharves of the great city and its suburbs. In it are three islands ceded to the national go-

New York City.

vernment, and fortified for the defence of the city. By the strait called "the Narrows," 7 miles from the lower part of the city, and which is, for the space of a mile, about 1 mile wide, with extreme depth of 86 feet, it communicates with the outer harbour, or bay proper, which extends thence to Sandy Hook Light, 18 miles from the city, and opens directly out into the ocean, forming one of the best roadsteads on the Atlantic coast. On the bar, at Sandy Hook the depth of water in the old channel is 21 feet at low tide, and 27 or 28 feet at high tide; but, in the New or Gedney's Channel, it is 32 at low tide, and 38 or 39 at high tide. The channel inside varies from 35 to 72 feet. The rise of the tide is nearly 7 feet. The depth of water at the wharves is sufficient for the vessels which they respectively accommodate, and increases rapidly outwards. The currents in the rivers and bay are very strong, keeping these waters open when the rivers and bays much farther south are frozen up. In very severe winters the East River is obstructed for a short time by ice; which, in a few cases, has collected so as to form a solid mass.

Defences.

The harbour has for a long period been well provided with defences, and these are being steadily augmented by the general government. The principal works are at the Narrows, which is the most important and most readily accessible avenue of approach. On the Long Island side, or shore of the channel, are Fort Hamilton and Fort Lafayette. On the Staten Island side, or shore of the channel, are batteries Hudson and Morton, Fort Richmond (in 1857 not completed), and Old Fort Tompkins. Quite near the lower point of the city there are fortifications on three islands,—Governor's, Bedlow's, and Ellis's,—and to these may be added Castle Clinton, which is now entirely dismantled, but occupies a good position, and might again be put in serviceable condition. The passage by the East River from Long Island Sound is defended by Fort Schuyler, a powerful work, situated at a narrow pass in the river, about 17 miles from the lower part of the city. Since 1854 there has been in construction a monster iron steamer, or steam battery, designed for use in the waters of the bay from Sandy Hook upwards, and intended to be, in fact, a movable fort of great efficiency. In 1857 Congress provided for the commencement of a fort opposite Fort Schuyler; for the erection of another on the site of old Fort Tompkins; for the repairs of those already established; and for extensive fortifications at Sandy Hook.

Surface.

The island was originally much diversified; and, in its upper portion, where least peopled, it still retains somewhat of its original character. The elevated rocky portions subsequently mentioned, vary from 70 to 130 feet above tide water—the valleys being often deep, and the hills precipitous. With the increase of population improvements have been made according to a uniform system, in laying out avenues and streets, levelling them, providing sewerage, &c. The island is traversed centrally throughout its lower part by a ridge, on each side of which the ground slopes gently to the water. There is also a line of elevation along the western side of the island in its upper part, from which the ground descends to the Hudson and the East River. A considerable portion of the lower part of the city, particularly that near the rivers, is artificial ground. The Battery, a public park at the southern extremity, was made upon a low ledge of rocks, much beyond the original water-line, at first of 10 acres; but since 1854 it has been extended to 17 acres.

Geological formation.

The island lies upon the upturned edge of the primitive range which extends through Westchester county and the New England States into Canada. The basis rock is gneiss, except for about 1 mile at the northern extremity, which is limestone, granular and primitive, and considerably quarried. The middle and northern portions are, or were, rough and broken, from the almost constant outcropping of the rock. The rock begins to make its appearance

in the neighbourhood of Thirtieth Street, and thence extends northward to Manhattanville. In many places it occupies large patches. On the west side of the city, not far from the Hudson River, between Fiftieth and Sixtieth Streets, and in some other parts, streets were cut through it. The lower portion is everywhere covered with alluvial and diluvial deposits, and is comparatively level. The soil is a sandy alluvion, and less fertile than in many other parts of the state.

New York City.

The history of the city is directly divided into three periods, during which it has belonged to the three governments,—Holland from 1609 to 1664; Great Britain from 1664 to 1783; and the state of New York since 1783. The most prominent events in each period are thus stated:—

Events in the annals of the city.

Dutch period.—1609, September 3, Hendrick Hudson entered New York Bay; 1613, the settlement of New Amsterdam was commenced; 1621, the Dutch West India Company commenced operations; 1626, the island was purchased of the Indians; 1652, New Amsterdam was incorporated, and the government passed from the West India Company into the hands of two burgomasters and five assistants, called schepens, and one schout or sheriff; 1664, September 9, the English took the province.

English period.—1664, name changed to New York; 1673, July, retaken by the Dutch and called New Orange, and held by them until ensuing year (treaty of 9th February 1674); 1686, James II. abolished the representative system, &c.; 1689, Leisler insurrection; 1690, a colonial congress assembled here; 1696, city lighted by ordinance; 1711, slave-market established in Wall Street; 1720, two per cent. laid on European imports; 1725, *New York Gazette* appeared; 1730, enlarged charter granted by Governor Montgomerie; 1732, stage routes established to Boston and Philadelphia, travelled once a month; 1741-2, "Negro plot" and yellow fever; 1765, a colonial congress assembled here; 1776-83, Revolution; 1776, September 21, a few days after the city had fallen into the hands of the British, a conflagration, destroying from one-eighth to one-fourth of the whole city; 1783, November 25, evacuation by British army.

American period.—1789, April 30, Washington inaugurated first president of the United States at Federal Hall, on site of present custom-house; 1798, 2086 deaths by yellow fever, which returned in 1803, 1805, and 1822; 1807, Fulton's steamboat on Hudson River; 1811, great fire; 1812, war with Great Britain, which suspended commerce; 1826, Erie Canal completed and great celebration; 1832, Asiatic cholera, 4360 deaths; 1835, December 16, 17, conflagration of 648 buildings, loss L.5,200,000; 1837, commercial revulsion; 1842, October 14, celebration of completion of Croton Aqueduct; 1845, conflagration of 546 buildings, loss L.1,250,000; 1849, cholera; 1850, Collins' steamers to Liverpool; 1851, May, Erie Railroad completed to Dunkirk; 1852, avenue railroads; 1853, World's Fair at Crystal Palace; 1854-5 (winter of), temporary depression of business, and suffering among the poorer classes; 1857, May 1, new city charter partially carried into effect; June 16, culmination of the riot resulting from opposition to the reorganization of the police department, followed through the summer by disturbances about municipal affairs; September and October, a terrible financial panic, which increased daily to 14th October, when the banks suspended specie payment; 1858, January 4, new city charter carried into full effect, with installation of new officers.

The foregoing enumeration of the principal occurrences in the annals of the city does not constitute or comprehend a correct outline of its real history. For a correct understanding of this, we must compare the progress of the city with the outline history of the domestic and foreign commerce of the United States; and by so doing it is readily

New York City. apparent that the remarkable prosperity of the former has resulted from the general prosperity of the latter.

Growth of New York the result of commerce.

Commercial interests originated the settlement of New York, developed its rapid growth, have always directly influenced its changes of fortune, and are now the main support of its greatness. With the fluctuations of the course of events, in regard to general commerce, there has always been a corresponding change in the ratio of increase of the population of the city and its general prosperity. After the close of the Revolution, an activity in business was everywhere apparent; and the citizens, by their persevering industry, were ultimately enabled not only to materially advance their own private interests, but also to promote the prosperity of the community at large. During the ten years from 1790 to 1800, the population of the city increased from 33,131 to 60,489, or at a ratio of 82.16 per cent. During this period the old world, involved in wars, was making constant demand upon the productiveness and industry of the new world. In the latter, the produce of New York and the Western States was pressing to the Atlantic, whence the shipping of the port of New York carried it abroad, returning again with goods for distribution, both in its own and neighbouring markets. Thus the business of the city increased wonderfully, and its attendant advantages drew thither capital and men to participate in the profits from the large investments there made. During the next decade, 1800 to 1810, there was a falling off of the ratio of increase of both population and wealth, and business enterprise was greatly depressed. Though the increase of population during this period was at a ratio of 59½ per cent., viz., from 60,489 in 1800 to 96,783 in 1810, the increase in wealth was but 8 per cent.: viz., from L.5,101,323 to L.5,407,572. In the first half of the succeeding 10 years, 1810-20, the foreign commerce of the city was entirely suspended for 3 years by the war of 1812-14 with Great Britain; after which, from 1815 to 1820, it again revived, and greatly promoted the prosperity of the city and nation. During this period, 1810-20, the increase in valuation was from L.5,407,572 to L.14,485,568, or 163 per cent.; while the increase in population was from 96,783 to 123,706, or only 28½ per cent.; which ratio is less than that of any other decade, and clearly illustrates the connection of the city's growth with commerce, since, during this same period, the increase of the population of the state was more rapid than ever before. From 1820 commerce steadily increased until 1825, in which year it reached a climax that was not again attained until 1831. In 1826 the completion of the Erie Canal opened a new avenue for trade and commerce, and assisted in the formation of the great speculations which soon characterized the financial career of the city. The reaction that followed this unnatural prosperity for a time prostrated all branches of business, and most seriously affected the commercial interests of the city. Since its recovery from that reverse of fortune, its commercial prosperity has, for the most part, been steadily augmenting, though of course somewhat affected by the changes in the tariffs of the national government, and by the changing relations of the nations with which it has had intercourse.

Progress of population.

Progress of Population of the City Proper.

Year	Population.	Year	Population.
1673	2,500	1814	95,519
1698	4,937	1816	100,619
1731	8,628	1820	123,706

1786	23,614	1835	268,089
1790	33,131	1840	312,710
1800	60,489	1845	371,223
1805	75,770	1850	512,547
1808	83,530	1855	629,810
1810	96,373		

The census of 1855 (June and July), is known to have

been very defectively taken, and it is highly probable that a correct enumeration would have shown a permanent population of above 700,000. The population of the immediate suburbs should also be considered in this account, since these are, in fact, parts of the metropolis.

On the East River side is the city of Brooklyn, which, since 1854, has comprised the former cities of Brooklyn and Williamsburg, and the town of Bushwick. The following table states the progress of population from 1840, in each of its divisions and in the whole of King's county, which consists of the city and several towns:—

Years.	Consolidated City of Brooklyn.				King's County. Total.
	Brooklyn.	Williamsburg.	Bushwick.	Total.	
1840.....	36,233	5,094	1,295	42,622	47,613
1845.....	59,574	11,338	1,857	72,769	78,691
1850.....	96,838	30,780	3,739	131,357	138,882
1855.....	148,774	48,367	8,109	205,250	216,355

On the New Jersey side of the Hudson, opposite the lower part of the city, are Jersey city and Hoboken. The population of the former, in its present area, was 11,473, and in 1855, 21,715; that of the latter was, in 1850, 2668, and in 1855, 5842; and this growth was but a continuance of previous duplication. Newark, the largest city in the state of New Jersey, situated 8 miles west of Jersey city, in 1830 had 10,953 inhabitants; in 1840, 17,290; in 1850, 38,894; and in 1855, 53,440; and this growth was, in great part, owing to that of New York, since the greater part of the business consists in producing manufactures for the New York market. The manufacturing city of Paterson, 16 miles from Jersey city, had 7596 inhabitants in 1840, 11,334 in 1850, and 23,960 in 1855; and its business likewise centres in New York.

Sixty of this class were engaged in pursuits requiring education, of which one-third were Mulattoes.

Civil con-
dition.

The census of 1855 is the first that affords data for comparison of the number of single, married, and widowed in the population. In the city the percentages of these classes were—single, 60·78; married, 34·41; widowers, 1·04; and widows, 3·63.

Voters and
aliens.

The number, and percentages of aliens and voters since 1821 in the city have been as follows:—

Census. Years.	Total Number.		Percentage to Pop.	
	Vo ers.	Aliens.	Voters.	Aliens.
1825.....	18,283	18,826	11·10	11·33
1835.....	43,091	27,669	15·95	10·24

1855.....	88,877	232,678	14·11	36·93

Adults un-
able to
read and
write.

Of adults (above 20 years) unable to read and write there were in the city in 1840, 7775 whites. The same class in 1850 (also above 20 years) consisted of 17,140 whites, and 1667 coloured; or a total of 18,807—of whom 2358 were native, and 16,449 foreign born. In 1855 the total number, white and free coloured, above 21 years, was 25,858, originating as follows:—

Families
and dwell-
ings.

Returns of 1850 and 1855 on Families and Dwellings.

Statements.	Dwellings.		Families.	
	1850.	1855.	1850.	1855.
Number	37,677	42,668	93,608	126,558
Persons in each.....	13·60	14·79	5·47	4·97

In 1855 the total value of dwellings, including the value of their lots, was reported at L.56,975,391, being an average of L.1333.

Owners of
land.

The number of all classes reported in 1855 as holding land by deed, contract, or perpetual lease, was 14,784, or 2·34 per cent. of the whole population. The total value of real and personal estate in the city and county of New York, for the year 1856, was L.106,612,599, of which L.70,935,849 was of real estate.

The valuation, as stated previously, is less than the real value of property assessed. In 1856 the total valuation of the "moneyed or stock corporations deriving an income from their capital" was L.19,648,062, consisting of L.17,363,539 personal estate, and L.2,284,523 real estate; on which the tax for city purposes was L.271,248.

Plan.

The general plan of the city is regular. In the old or southern part, now devoted wholly to business, the principal streets were in part formed according to the shape of the island, and hence its plan is not continuously uniform, although each of its large divisions is by itself comparatively regular. The uniform plan of avenues and streets com-

mences at Houston Street, 1 mile from the City Hall, and 1½ miles from the Battery. Above this point the island is divided longitudinally by fourteen parallel Avenues. 100 feet wide, which are crossed at right angles by 156 streets, numerically designated, running directly from river to river, and 80 feet wide, excepting sixteen. The latter are 100 feet wide, of which Fourteenth Street is the first that extends entirely across the island. The principal street is Principal Broadway, especially that main portion of it which occupies the central ridge of the island, extending in a straight line, and with uniform breadth of 80 feet, nearly 2½ miles, from the Battery to Tenth Street (Grace Church). It is mainly occupied by stores, but it also contains the principal hotels and theatres, besides several banks and other prominent structures. Although a very large proportion of the buildings in this street are of costly construction, so that there is not a more splendid business thoroughfare in the world, yet its general aspect is impaired by a remarkable diversity of architecture, for almost every block comprises several fronts of marble, sandstone, and brick. The Bowery is the next most important of the thoroughfares; it is more plainly built, and is traversed by some of the city railroads. Fifth Avenue is the central street of the most elegant and fashionable portion of the city, and is wholly occupied by very costly private residences, which are chiefly constructed of brown sandstone; and several fine churches. Like all other large cities, however, New York has many streets which are lined with cheap, miserable, and densely-peopled tenements, which, with their inmates, afford a sad contrast to the display of wealth and magnificence in other sections.

Besides the great central park, the city has seventeen public squares and other arcas, for the most part of small extent, though varying in size, their aggregate area being 170 acres; they are generally inclosed with handsome iron fences, and ornamented with trees, fountains, &c., affording pleasant promenades. The new central park, designed in 1853, and not yet completed, extends from Fifty-ninth to One Hundred and Sixth Street, between Fifth and Eighth Avenues. It is 2½ miles long by half a mile wide, comprising 776 acres, including the present distributing reservoir (occupying a position nearly central), the ground taken for a new reservoir, and the Arsenal grounds belonging to the state, and valued, as first taken in its unimproved state, at L.1,076,947. Its surface is somewhat uneven, and its natural configuration is used as the basis of the improvements. There are two beautiful parks, each comprising a square, which are private property.

Owing to the natural shape of the island, to the fact that it was first settled at its southern extremity, and to the eligibility of that section for the extension of trade and commerce, it has resulted that the growth of the city has, with successive years, been manifested by an increase of houses and business buildings in a northward direction. In the southern and business section the number of dwellings has yearly decreased, the old houses being pulled down, and stores or other establishments erected. Therefore in that section the number of inhabitants, instead of increasing or remaining stationary, has rather diminished, and the absolute increase of population has been most apparent in the northern section. In the spring of 1853 the city was quite compactly built from the Battery to Forty-second Street, 4 miles. In that year, and somewhat before, a great impulse was given to the northward movement by the erection of the Crystal Palace; and also by the sale on the part of the city of large tracts of ground in that section. The increase, since 1853, of population in the northern sections has been very great, and in part attributable to the introduction and extension of city railroads.

The several sections of the city are characterized by considerable uniformity in their respective styles of building. In the upper parts many of the blocks consist of houses

fices.

constructed precisely alike. Building lots are almost everywhere of equal width. In the older streets the buildings are almost wholly of brick, which is now by far the chief building material in all sections; though of late years the use of freestone, marble, granite, and iron, for the front of buildings, has become quite general.

The City Hall occupies the centre of the park, in the lower part of the city. It is a very large and handsome edifice, built, in combined Ionic and Corinthian orders, of white marble, except its north side, and surmounted by a cupola, which is crowned by a statue of Justice. It was constructed between the years 1803 and 1812, at a cost of L.112,232. It contains 28 apartments, used as the public offices of the mayor and other members of the city government. The principal apartment, called the Governor's Room, contains a fine collection of portraits of men celebrated in the civil, military, and naval history of the country. In the common council-room is the identical chair occupied by Washington when president of the first American Congress, which assembled in this city. In the rear of this edifice is another large building, occupied by the principal courts and some public offices; and east of it is the Hall of Records, in which are preserved all the records and public documents of the city.

The Merchants' Exchange, occupying an entire block, is built of Quincy granite, and cost about L.375,000. Its front has a recessed portico with 18 columns, each of which is a solid block of granite, 38 feet high, $4\frac{1}{2}$ feet in diameter, and weighing over 40 tons. Its central rotunda is elaborately constructed of white marble, and lighted by a very lofty dome, which is in part supported by 8 Corinthian columns of Italian marble, 41 feet high.

The Custom-House (on the site of the old Federal Hall, where General Washington was inaugurated the first president) is built of white marble, in the Doric style, after the model of the Parthenon, with two grand porticos, each having 8 massive columns; its principal hall is circular, surmounted by a dome, supported by 16 Corinthian columns, 30 feet high, beautifully wrought with capitals of the most exquisite workmanship. Its construction occupied seven years (1834-41); and its cost, ground included, was L.248,900.

The Post-Office is not noteworthy for its architecture, though it is so for its history. It was formerly the Middle Dutch Church, and was erected before the Revolution. Much of its interior wood-work and its steeple were brought from Holland during the Revolutionary war; this church, in common with others used by the British, was much injured from its occupation as a prison, hospital, &c. In 1790 it was repaired, and continued to be used for public worship until rented by the United States government for the general post-office of the city.

The Hall of Justice, or city prison, is an extremely massive granite building of Egyptian architecture, and occupies an entire block. Its gloomy aspect has obtained for it the general name of "The Tombs." Its front has a recessed portico, supported by 14 huge columns. It is chiefly occupied as a prison, though in part by the criminal courts, and in part as a police station.

The Crystal Palace was erected in 1853 for the World's Fair, or "Exhibition of the Industry of all Nations," on Reservoir Square, 3 miles from the City Hall. Since the close of that exhibition it has been used only at intervals, and then for sundry fairs, exhibitions, and festive assemblages. It has a somewhat octagonal form; each main diameter is $365\frac{1}{2}$ feet long, and the area of its flooring is 173,000 square feet. The dome is 100 feet in diameter, and 123 feet high. Excepting the floors, the building was constructed entirely of iron and glass,—requiring 1800 tons of iron, 55,000 square feet of glass, and 750,000 square feet of timber.

VOL. XVI.

The State Arsenal, $4\frac{1}{2}$ miles from the City Hall, is a large edifice, containing arms and munitions belonging to the state. It was erected in 1848, and is in the Gothic castellated style, presenting a massive and appropriate appearance.

The City Armoury, or Down-Town Arsenal, is a handsome structure in the Gothic style, two stories high, built of blue stone. It is constructed on the best plan for defence; as, for example, its windows are only 18 inches wide, so that in case of an attack it could be defended with success by fifty men. In January 1855 the citizen soldiery of the city (comprised in the First Division, New York State Militia, in four brigades) consisted of—infantry, 3906; cavalry, 1291; and artillery, 1589: total, 6786.

The hotels of New York are generally very large, and noted for their excellence; while a considerable number cost fully L.200,000, and are remarkable for their splendour. Upon Broadway alone there are about twenty-five, all elegant in their appointments, and severally accommodating from 200 to 800 guests. Prominent among these, as the oldest, and not surpassed in substantial excellence by any of the more recent establishments, is the Astor House, a rare example of popular favour, deservedly secured and long and surely retained. It was erected by John Jacob Astor, at a cost of L.165,000, and opened in May 1836. The building is constructed of Quincy granite, in the most substantial manner, and contains about 400 rooms. The St Nicholas Hotel, opened in 1853, and subsequently much enlarged, now constitutes the most capacious and costly hotel in the world. It is built of white marble and freestone, and is noted for the splendour of its apartments and its general magnificence. The Metropolitan Hotel, built of freestone, and a very imposing and attractive edifice, was opened in September 1852. Of similar character with these three are the Clarendon, Everett, Brevoort, St Germain, and Lafarge. To this list might be added others of nearly equal rank. The United States Hotel, built of marble, at a cost of L.72,000, containing about 250 rooms, was the first of the *mammoth* hotels. Many other hotels are very large, elegant, and well appointed; but their great number precludes particular mention. Hotel-keeping, as practised in New York by the best houses, is brought nearer perfection than in any other city in the world.

Until the summer of 1852 the omnibuses of the city afforded almost the only means of cheap and regular conveyance. Up to that time these were very extensively used by the people, as they yet are, except in certain thoroughfares, where they have been superseded by the railroads. The city cars of the Harlem Railroad commenced running in June 1833, and at the same rate of fare as the stages. In August 1852, notwithstanding the strenuous opposition of thousands against the establishment of railroads through the leading avenues of the city, the Sixth Avenue and the Eighth Avenue lines commenced operation; and in July 1853 the Second Avenue and the Third Avenue lines. These channels of travel are now better patronized than the stages ever were, or ever would have been, had the roads not been formed. On each line the fare is $2\frac{1}{2}$ d., without regard to the length of the routes, which vary from $2\frac{3}{4}$ (Fourth Avenue) to $5\frac{1}{4}$ miles (Third Avenue). The cars (which are drawn by horses or mules, and are about twice the length of an omnibus) run day and night, at intervals varying from two to thirty minutes, according to the public requirements. Their successful operation has resulted in their establishment in other cities.

There are thirty lines of omnibuses, having in all about 600 in daily use. The routes of these lines vary in length from three to five miles. The uniform fare is 3d. With these Broadway is often completely blocked from morn till midnight, all efforts to remove or supersede them having proved ineffectual. The number of hacks is not propor-

New York City. tionate to the population of the city, owing mainly to the greater facilities afforded by the more popular conveyances, and somewhat to the extortionate demands of the hackmen, though their rates are duly prescribed by law. By census of 1855, 1741 persons were occupied as drivers; 5838 as carters and draymen; 3052 as porters; and 1004 as boatmen and watermen.

Ferries. Between New York and its immediate suburbs across the rivers, steam ferry-boats are constantly plying. On the principal ferries these are run throughout the night as well as the day. From the populous part of the city there are, across the East River, fourteen ferries, and across the Hudson four; and from the upper part of the island there are others across each river. On the East River the ferryage is (excepting for the longest routes) 1d.; on the Hudson 1½d. The number of passengers, vehicles, &c., crossing daily is very great. In the morning and towards night the boats are often crowded. To many places near the city steamboats are run, especially in summer, at very low rates of fare.

Manufactures. In its manufactures, as well as commerce, New York is the first city in America. In 1850 the number of hands employed in manufactures, mining, or the mechanical arts (establishments producing annually to the amount of L.104), was 80,302; capital invested L.6,126,615; product annually L.1,882,958. The branches which are here most extensively prosecuted are those directly developed by the great trade and commerce.

Building of vessels. Ship-building is carried to a high degree of perfection; and in speed, beauty of model, and internal convenience, the vessels built here are nowhere surpassed.

Table showing the number of vessels of all kinds built in the district of New York, with their aggregate measurement, from 1843 to 1857, compiled from the Treasury Reports:—

Fiscal Years.	Ships & Barques	Brigs.	Schooners.	Sloops and Canal Boats.	Steam-boats.	Total Vessels.	Total Tonnage.
1843	5	2	8	102	5	122	13,179
1844	11	6	16	89	14	136	18,026
1845	18	2	25	130	17	192	26,621
1846	11	3	37	160	23	234	29,465
1847	16	2	43	117	15	193	37,591
1848	26	3	59	200	19	307	57,977
1849	15	7	44	145	17	228	37,933
1850	26	2	42	104	28	202	55,525
1851	23	1	56	81	47	208	77,214
1852	24	2	46	38	43	153	69,054
1853	18	5	66	97	58	244	68,454
1854	40	7	63	81	49	240	93,496
1855	40	5	76	219	41	381	92,697
1856	24	7	35	108	17	191	49,317
1857	28	5	37	73	21	164	43,118

The construction of splendid ocean steamers has, since 1846, formed a distinguishing feature in the business of the New York ship-yards. Of these there have been launched about 120, all of which have fully satisfied, and in fact exceeded, the expectations of their builders; while several have become celebrated throughout the world as superior to all, of every other nation, previously afloat. So great, however, has been the rivalry between American and British ship-builders, that, since 1850, the marine of each nation has been yearly increased with new steamers, constructed to surpass all their predecessors. This rivalry, still continued, promises to furnish both of these countries, and others also, with a vast number of steamers, which will greatly promote their respective interests, and aid in extending civilization over the globe.

Tonnage in steam navigation. The increase in the amount of the tonnage employed in steam navigation since 1848, and owned in the district, is exhibited in the following table:—

Years.	Registered.		Enrolled & Licensed.		Total.	
	Tons.	95ths.	Tons.	95ths.	Tons.	95ths.
1848	6,523	73	57,705	41	64,229	19
1849	10,642	76	61,175	92	71,818	73
1850	36,148	47	58,967	9	85,115	56
1851	52,392	68	69,148	89	121,541	62
1852	63,860	33	77,063	84	140,924	22
1853	76,851	78	88,311	53	165,163	36
1854	82,607	73	101,487	41	184,095	19
1855	89,105	9	107,692	88	196,798	2
1856	68,777	26	107,820	67	176,597	93
1857	69,051	67	111,526	89	180,578	61

New York City.

The following statement from the annual reports of the Secretary of the United States Treasury exhibits the registered, the enrolled and licensed, and the total tonnage belonging to the district of New York, in each decennial year from 1825:—

Years.	Registered.		Enrolled & Licensed.		Total.	
	Tons.	95ths.	Tons.	95ths.	Tons.	95ths.
1825	156,728	14	147,756	8	304,484	22
1835	191,626	43	185,071	29	376,697	72
1845	248,717	...	301,642	48	550,359	48
1855	737,509	37	550,725	29	1,288,234	66
1857	802,356	10	575,068	51	1,377,424	61

Nearly all of the enrolled and licensed tonnage is employed in the coasting trade; but there are no complete official accounts of this trade. The law exonerates vessels engaged in it from entering or clearing at the custom-house, unless they have foreign goods or distilled spirits on board; and comparatively few vessels which arrive from a domestic port come within this exception. The record of clearances coastwise (as many such vessels take foreign goods or spirits) exceeds the number entered; but even this list is far from including all which are engaged in this trade. The following summary, derived from the custom-house records, is for the calendar years mentioned:—

Years.	Entered Coastwise.		Cleared Coastwise.	
	Vessels.	Tons.	Vessels.	Tons.
1849	1855	424,976	3994	805,589
1851	1768	455,542	4803	1,214,942
1853	1733	507,531	4789	1,310,697
1855	1966	614,045	4563	1,378,889
1856	1669	539,461	4696	1,482,310

The coastwise trade is carried on entirely by American vessels, built and owned within the United States, as foreign vessels are by law prohibited from engaging in it.

In addition to the foregoing, we give the following statement of coastwise arrivals for three years, collected from the returns of Mr James Thorne, boarding-officer, United States revenue department, Whitehall:—

Years.	Steamers.	Ships.	Barques	Brigs.	Schooners.	Total.
1855	460	220	208	422	4992	6302
1856	523	150	177	371	4888	6109
1857	521	117	129	304	5026	6097

NOTE.—In the above no sloops are included. These, if added to the many schooners from Virginia and Philadelphia, with wood and coal, which, though consigned here, discharge their cargoes at Brooklyn, Williamsburg, Jersey city, and the adjacent towns on the Hudson, and are not boarded owing to the remoteness of these points for general business, would make the number much greater. The officer estimates the schooners that arrive at the above places and are not reported, at eight per day; which he thinks is an estimate rather under than over the actual number. This would give for each year 2920 additional schooners to be added to the coasting trade, making the whole number of coastwise arrivals in 1855, 9222; in 1856, 9029; and in 1857, 9017. In the above statement the steamers arriving from New Orleans, via Havana, are included.

The trade of the city with the interior of the Union

New York City. Trade with the interior. vastly exceeds its foreign commerce; but of this there are no full reports. The available data consist of the accounts of the articles brought to tide-water by the Erie Canal, and the statistics of freight-traffic on the railroads which centre in the city. Of the latter the most important is the Erie Railroad, which bears a relation to the entire southern portion of the state, and northern portion of Pennsylvania, very similar to that sustained by the Erie Canal to the northern part of the state. The eleven railroads leading from the city have an immense and ever-increasing traffic; and they directly connect the metropolis with every important section of the country. The receipts of the city from the Erie Canal are approximately known, because the greater part of the receipts at tide-water at Hudson, near Albany, from the same source, are directly sent to New York. The following statement shows the aggregate tonnage and value of the property which came to the Hudson River, on all the canals, during the year 1856:—

	Tonnage.	Value.
Product of the Forests	858,771	L.2,176,431
Agriculture	1,023,417	10,379,644
Manufactures	50,454	934,199
Merchandise	14,073	1,103,685
Other articles	176,754	882,365
Total	2,123,469	L.15,476,324

Of the total tonnage, the amount from Western States and Canada, arriving by way of the Erie Canal, was 1,212,550. The amount of the produce of the state of New York, arriving by all the canals, was 374,580 tons. Number of barrels of flour by all the canals, 1,130,509; bushels of wheat, do., 11,776,332 (or 2,355,266 barrels of flour; total, 3,485,775 barrels wheat flour); bushels of corn, do., 9,587,714.

The property which went up the canals in 1855 was in tons 638,597, and in value L.23,634,234; the same in 1856 was in tons 650,943, and in value L.27,944,001. Aggregate of property brought and taken in 1855, L.39,667,732; in 1856, L.43,420,325.

Foreign commerce. In surveying the business of New York, and comparing it with that of other American cities, it is at once seen that the point in which it is relatively greatest is its foreign commerce. From this source, more than any other, New York derives its general pre-eminence. Compared with the other great seaports of the world, the ocean commerce of New York is more extensive than any, excepting perhaps London and Liverpool. For this branch of industry the city naturally possesses uncommon advantages; but its remarkable prosperity has been owing mainly to the enterprise of its merchants. The following table is a summary view of the percentage of New York in the entire foreign commerce of the United States, at intervals of five-years from 1825:—

Fiscal Years.	Tonnage entered.	Tonnage cleared.	Value of Exports.	Value of Imports.	Duties collected.
1825	26-21	21-65	44-80	51-92	78-37
1830	27-78	24-19	23-93	54-54	68-48
1835	23-35	13-12	23-86	59-58	74-61
1840	23-41	17-38	22-85	53-05	55-84
1845	19-66	16-22	29-83	58-78	64-18
1850	26-33	22-52	25-44	57-96	61-73
1855	29-20	23-40	36-48	59-09	61-58
1857	28-33	24-82	34-27	61-67	...

Tonnage entered and cleared from New York.

The next two tabular statements, derived from the "United States Treasury Report on Commerce and Navigation," exhibit the number of vessels and amount of tonnage entered into and cleared from the district of New York for foreign ports, in each fifth year from 1826. The years end with September to 1840, thence with June:—

Vessels and Tonnage entered into District of New York.

New York City.

Fiscal Years.	American		Foreign		Total	
	Vessels.	Tonnage.	Vessels.	Tonnage.	Vessels.	Tonnage.
1826	...	248,176	...	26,285	...	274,461
1830	...	273,790	...	31,391	...	305,181
1835	1,528	374,602	480	91,063	2,008	465,665
1840	1,443	417,443	512	128,488	1,955	545,931
1845	1,450	439,676	558	139,542	2,008	579,218
1850	1,882	734,431	1,281	410,900	3,163	1,145,331
1855	2,588	1,377,738	1,185	358,169	3,773	1,735,907
1857	3,014	1,584,764	1,054	450,885	4,068	2,035,649

The number of arrivals from foreign ports entered at the custom-house is always greater than the official record of clearances, because many vessels entering from abroad clear for a coastwise port.

Vessels and Tonnage cleared from District of New York.

Fiscal Years.	American		Foreign		Total	
	Vessels.	Tonnage.	Vessels.	Tonnage.	Vessels.	Tonnage.
1826	...	208,202	...	19,655	...	227,857
1830	...	210,535	...	32,620	...	243,155
1835	1,226	289,268	433	77,121	1,659	366,389
1840	1,067	283,149	503	125,619	1,570	408,768
1845	1,127	341,094	561	142,431	1,688	483,525
1850	1,379	596,812	1,230	385,666	2,609	982,478
1855	1,941	1,091,244	1,169	354,510	3,110	1,445,754
1857	2,307	1,310,875	1,047	445,566	3,354	1,756,441

The next tabular statement exhibits the value of im-ports, the duties collected thereon, and the value of ex-ports, and ports in each fifth fiscal year from 1820. The years end with September 30th to 1840, and thereafter with June 30th:—

Fiscal Years.	Value of Imports.	Duties collected.	Value of Exports.
	L.	L.	L.
1820	...	1,143,325	2,451,978
1825	10,419,783	3,281,684	7,089,824
1830	8,053,342	3,127,613	3,680,542
1835	18,278,089	2,416,135	6,135,661
1840	12,515,526	1,493,323	6,751,805
1845	14,561,955	3,594,852	6,990,573
1850	24,305,736	5,198,532	9,912,571
1855	32,188,648	6,803,926	20,912,898
1856	41,314,728	8,880,935	22,042,927
1857	47,121,696	8,808,589	26,376,387

The returns previous to 1852 are from a United States Treasury document, and those of subsequent years are from the statements published in Hunt's *Merchants' Magazine*. Imports The latter also presents the following classification of im-ports and exports:—

	1856.	1857.
Foreign Imports.		
Entered for consumption	L.31,268,354	L.29,464,603
Entered for warehousing	6,160,078	12,974,093
Free goods	3,631,686	3,340,940
Specie and bullion	234,600	1,342,050
Total entered at the port	L.41,294,718	L.47,121,686
Withdrawn from warehouse ...	4,569,606	5,822,957

The imports in 1857, at New York, were even greater than the total imports into the whole United States in any fiscal year previous to 1853. Prior to 1855 about one-half of the imports at this port were dry goods, but since that date the enormous increase has been chiefly in general merchandise:—

Years.	Dry Goods.	General Merchandise.	Total Imports.
	L.	L.	L.
1854	19,247,841	20,559,344	39,807,185
1855	13,108,005	19,080,638	32,188,643
1856	17,895,555	23,399,163	41,294,723
1857	19,312,304	27,809,387	47,121,691

New York
City.*Description of Dry Goods Imported for Two Years.*

Articles.	1856.	1857.
Manufactures of wool.....	L.5,178,249	L.5,488,085
Manufactures of cotton.....	3,173,270	4,082,083
Manufactures of silk.....	6,242,410	6,185,393
Manufactures of flax.....	1,796,205	1,893,034
Miscellaneous dry goods.....	1,566,399	1,657,523
Total dry goods.....	L.17,895,533	L.19,306,118

Which were disposed of as follows:—

Entered for consumption.....	L.16,243,806	L.15,590,337
Entered for warehousing.....	1,651,727	3,715,781

Under the inducement to await the operation of the new tariff, which provided for an important reduction in duties on 1st July 1857, the stock in bonded warehouses had on that day accumulated to the amount of L.7,695,466, against the corresponding value of L.2,928,627 one year previous.

The exports to foreign ports during the fiscal year 1857 were larger, both in specie and produce, than during any previous year. Classification for two fiscal years:—

Articles.	1856.	1857.
Domestic produce.....	L.15,630,464	L.15,818,526
Foreign merchandise, free.....	264,354	499,350

&c.Moneyed
institutions.

For a series of years the city of New York has proved to be the regulator of the policy adopted in financial affairs throughout the Union, and may now be considered as its financial centre. This has naturally resulted from its being the leading channel of imports and exports; and thus it has become the pivot upon which almost the whole business of the country has turned. Since 1849 this has especially been the case, by the constant influx of vast amounts of gold from California; which, being brought first of all into the city of New York, has materially aided in augmenting the number and capital of all classes of its moneyed institutions. Meanwhile, other causes have been producing a gradual and powerful concentration of capital at New York from all parts of the Union. During the same period the banks and private bankers of every state have increasingly made this city the depository of their surplus funds, and more particularly since the practice of allowing from 4 to 6 per cent. interest has prevailed. Hence, of late years, exchange on New York has been considered as equivalent to cash funds on hand by all engaged in the banking business. New York has for many years been a creditor of the whole Union. Thereby it has obtained a vast credit, and, consequently, the control of immense capital, belonging, in small and large sums, to remote parties. This rapid accumulation of capital has not only aided to build up New York, but it has at length been regarded as belonging permanently to the interests of the city. From 1849 to 1857 the imports of New York increased 133 per cent.; the bank capital 160 per cent.; the average bank loans 125 per cent.; and the average bank deposits about 225 per cent.

In 1830 the capital of the banks in the city was L.3,183,330; on 1st February 1834 (twenty-one banks) L.3,929,472; and on 1st January 1837 (twenty-four banks) L.4,346,080. The general banking law was passed by the legislature 18th April 1838. In 1845 the number of banks was twenty-four, and their capital L.4,809,184; and there was no increase until 1849. In that year the capital was raised to L.5,095,390; at the close of 1850 it was L.5,634,645; in July 1852 (forty banks), L.7,465,610; in January 1854 (fifty-seven banks), L.9,928,622; in July 1856, L.11,077,146; and in July 1857 (fifty-six banks), L.13,453,352.

Without presenting an account of the progress of the

banks during a series of prosperous years, and their usual operations in such years, we shall briefly sketch the features of their condition through the year 1857, which opened favourably with a very buoyant stock market. Throughout January money was in good demand, and a moderate stringency existed. In February the rates gradually declined, and stock securities were pretty well sustained. In March there was more active movement, with an advance in prices. In April money was abundant, and the banks gradually increased their discount lines upon an increasing specie basis and a larger deposit account; and on the 11th of the month their loans were L.24,036,395, being a higher point than ever before known. The highest point in 1856 was 2d August, L.23,381,488; and the highest in 1855 was on 1st September, L.20,924,365. Through May the money market was easy, stocks were buoyant, and the banks maintained a very uniform movement in the discount and specie departments. On 6th June the loans and discounts were L.24,028,868, and for four weeks remained above L.24,000,000, and at about the same amount; but in that time the specie decreased from L.2,736,395 to L.2,271,058, owing to the active shipments. From 3d July the loans increased daily until 8th August (the highest point of the expansion), when they amounted to L.25,432,756, being an increase of L.1,454,796 in five weeks, or at an average of L.48,489 each business day. With this expansion in discounts there was a steady decrease in the specie reserve. During the last of the five weeks just mentioned the loans and discounts increased L.308,373, while the specie decreased L.245,965. Thus, on the 8th August, the loans and other chief items of the accounts of all the banks in the city were, in comparison with their condition on 3d January, as follows:—

Date.	Loans.	Specie.	Circulation.	Deposits.
Aug. 8.....	L. 25,432,756	L. 2,445,281	L. 1,871,192	L. 19,674,249
Jan. 3.....	22,739,402	2,327,547	1,792,104	19,967,957
Increase....	2,693,354	117,734	79,088	
Decrease in deposits.....				293,708

Apprehensions of coming troubles were immediately excited in the minds of many financiers. Thenceforward the banks rapidly contracted their loans; at the same time their specie reserve ran down, and the money market daily became more stringent. The remarkable extent of this contraction is readily apparent from the following tables:—

Increase of the Currency, &c., in Nineteen Weeks.

Date.	Loans.	Specie.	Circulation.	Deposits.
Aug. 8.....	L. 25,432,756	L. 2,445,281	L. 1,871,192	L. 19,674,249
Mar. 28.....	23,517,502	2,359,523	1,765,378	19,294,696
Increase....	1,915,254	85,758	105,814	379,553

Decrease of the Currency, &c., in Four Weeks.

Date.	Loans.	Specie.	Circulation.	Deposits.
Aug. 8.....	L. 25,432,756	L. 2,445,281	L. 1,871,192	L. 19,674,249
Sept. 5.....	23,379,447	2,131,239	1,806,910	16,560,687
Decrease....	2,053,309	314,042	64,282	3,113,562

The foregoing statements show that the contraction in four weeks after 8th August, was much greater than the expansion in nineteen weeks before that date.

The next table shows, on comparison with the first table, that the contraction in six weeks after 8th August was also much greater than the expansion during the thirty-one weeks before that date; viz., from 3d January:—

New York
City.*Decrease of the Currency, &c., in Six Weeks.*

Date.	Loans.	Specie.	Circulation.	Deposits.
	L.	L.	L.	L.
Aug. 8.....	25,432,756	2,445,281	1,871,192	19,674,249
Sept. 19....	22,661,960	2,824,200	1,682,039	15,785,991
Decrease ...	2,770,796		189,153	3,888,258
Increase in specie reserve		378,919		

On 26th September the banks in Philadelphia and Baltimore suspended specie payments; but the banks in New York city, and in part of New England, published that they were able to maintain themselves as specie-paying institutions. This announcement inspired hope; but the banks, instead of giving to their customers the expected (and in fact promised accommodation), continued to diminish their loans. The financial panic waxed more intense, surpassing description. Commencing in August, business of almost every kind was gradually brought to a stand. In almost every place the operations of manufactories, and shops and stores, were reduced; and thousands of operatives and employés were discharged. Through September the gloom deepened every day. Men were everywhere calling for aid, and in vain. Property seemed to have no fixed or certain value. In the fore part of October the number of mercantile suspensions and failures augmented rapidly over the corresponding daily announcements in September. The paper of many of the most prominent and reputable mercantile firms, of several of the largest private banking-houses, and of some great railroad corporations, was protested. The suspension of a few of the banks in the city, and of a score of those in the interior of the state, and perhaps a hundred in other states, aided in bringing about the general suspension by inducing a general run upon all other banks. On Tuesday, 13th October, nineteen banks ceased to pay specie to bill-holders and depositors; but to the latter either paid notes or closed their doors entirely. In the evening of that day all other banks resolved to suspend on the ensuing day. This course was immediately followed throughout the Union.

It is generally considered that the panic which brought on the crisis was owing chiefly, if not wholly, to the imprudent course of the banks in expanding their discounts, and then too suddenly contracting them. The actual suspension of the banks was owing to the disgust and indignation of the mercantile classes, who, having been injured by the banks, retaliated by using their own power. On this point, the *London Times* of 26th October remarked that—"The entire suspension of specie payments by the New York and Boston banks, reported this morning by the American mail, is the most satisfactory announcement that could have been looked for. Had the step been taken a fortnight earlier, an immense amount of ruin might have been averted. The banks, after having, by their mismanagement, brought about the state of affairs which rendered the panic possible, sought to save themselves by the sacrifice of the whole mercantile community; but the public, at last, took the matter in their own hands, and forced them to a stoppage, which placed them in the same condition with their victims, and thus terminated the struggle." The *Times* regarded the matter in its true bearing, attributing the blame to the proper parties.

The returns for the week of suspension, ending 17th October, being ten weeks from 8th August, are thus compared with the returns of that date:—

Date.	Loans.	Specie.	Circulation.	Deposits.
	L.	L.	L.	L.
Aug. 8.....	25,432,756	2,445,281	1,871,192	19,674,249
Oct. 17.....	20,259,543	1,634,003	1,684,881	11,019,709
Decrease...	5,173,213	811,278	186,311	8,654,540

showing several still greater changes in each item, and particularly in the decrease of specie and deposits, these having been withdrawn by bill-holders and depositors.

After suspension the banks rapidly augmented their specie to a sum several millions above any previous total, gaining from 17th October (when L.1,634,003) to 12th December (when L.5,428,928) the sum of L.3,794,925. But no ease in the money market was realized amongst business men for seven or eight weeks, and there was no important change in financial affairs until 11th December. On that day the specie in the banks had accumulated to L.5,415,000, and it was then resolved to resume specie payments on the next day. In the first week after resumption the specie increased nearly L.415,000, swelling the amount to L.5,824,855, in the face of a very active shipment to foreign ports. At the close of the year the banks of Philadelphia, Baltimore, &c., had not resumed.

Although it is reasonable to suppose that another revolution may occur in an interval of twenty years, it is probable that this of 1857 will produce at least three beneficial results throughout most of the states, viz.,—The abolition of small bank notes (under L.1 or L.2); the establishment of a specie basis of not less than 1 to 3 (or 4) of circulation; and the requirement of ample securities for bill-holders and depositors.

On 1st January 1857 there were sixteen savings-banks Savings-banks in the city, which had on deposit L.6,760,879. Number of depositors' accounts, L.151,559. During 1856 there were 193,317 deposits, amounting to L.3,053,992; and 139,422 withdrawals, amounting to L.2,412,978. Interest received on stocks and securities, L.1,855,110. Interest received on bonds and mortgages, L.181,854. Interest allowed to depositors, L.286,973.

The daily newspapers, with many of the weeklies and The press. other periodicals, are remarkable for their intrinsic merits, size, cheapness, and immense circulation. Each of the leading newspaper establishments employs a very large amount of capital, and is furnished with the best presses and other equipments known among printers. The earliest newspaper in New York was commenced on 16th October 1725, and printed weekly. Before the Revolution about 90 others had been in existence. In 1775 there were 4 newspapers. In 1832, 64 newspapers and periodicals. According to the census of 1855, there were in that year 145 newspapers and 78 other periodicals, published as follows:—Daily, 19; tri-weekly, 1; semi-weekly, 8; weekly, 87; semi-monthly 10; monthly, 87; quarterly, 13; semi-annually, 2; annually, 3. Four of the daily papers are reputed to have each a circulation above 30,000 (their proprietors not unfrequently claim much more); and several of the weeklies circulate to regular subscribers each from 40,000 to 50,000 copies. One weekly, devoted to news and politics, has 175,000 of a regular circulation, almost wholly to subscribers; while another, devoted to tales and "light reading," is believed to have above 300,000. One of the popular monthly magazines has 170,000, and a religious monthly newspaper above 200,000.

The public and private provisions for the general Education. Education. tion of children, youth, and adults, are upon a liberal scale. It is believed that less attention is given to education by the illiterate and poor classes than in most large cities of the Union; but these are chiefly of foreign birth, and feel compelled to make use of their children to gain a livelihood. By the census returns it appears that the greater number of the adults unable to read and write are of foreign birth.

The number of public schools under the jurisdiction of Public the Board of Education, in the year 1855, was 271, viz.,—schools. Grammar, for boys, 47; grammar, for girls, 48; primary, 101; coloured, 14; corporate and asylum, 28; evening, 29; normal, 3; and the Free Academy. The whole num-

New York
City.

New York City. ber of teachers employed in the several schools was 1067, consisting of 187 males, and 880 females. The amount expended for purposes of education during the year was L.191,217; of which the sum of L.27,649 was received from the state funds, and L.163,568 raised by tax on property in the city. In the grammar and primary schools (238) the whole number taught in 1855 was 137,874; the annual average attendance was 47,858; and the cost (total L.112,507) per pupil was, on the whole number taught, 15s. 5d.; on average annual attendance, L.2, 4s. 5d. The evening schools, for adults, &c., were attended by 12,762 persons, and their support cost L.6796. The normal schools, with 782 pupils, cost L.1256 for support. The Free Academy, established in 1848, crowns the system of public school education. In 1855 it had 696 pupils, and its support cost L.7714. Its spacious edifice is built in the Gothic style, after the manner of the town-halls of the Netherlands, and cost, with site and fitting up, L.22,811. It has 23 teachers, a library of 5000 volumes, besides 10,000 text-books, &c., excellent apparatus, laboratory, and cabinets.

Academies. Select schools and academies, conducted by individual and associated enterprise, are proportionately numerous. Some of the seminaries for young woman are of very high reputation, and have each several hundred pupils.

Colleges. Columbia College was founded in 1754 by royal charter as King's College, and received its present name in 1784. Its trustees and officers are of the Protestant Episcopal Church. It is richly endowed, possesses a valuable library, and has usually about 120 students in its collegiate department. It occupied its ancient position near the city-hall, in beautiful open grounds, shaded by venerable trees, until 1857, when it was removed to the upper part of the city, and its former site is now covered with warehouses. The university of the city of New York was founded in 1831, and is non-sectarian. Its edifice, fronting Washington Square, is one of the finest structures in the city, and the most costly collegiate building in the country. It is constructed of marble, in English Gothic architecture; and its central part, used as the principal chapel, is an imitation of the celebrated King's College chapel, Cambridge, England. There are three flourishing medical colleges, and several minor medical institutes. The College of Physicians and Surgeons was founded in 1807; medical department of the university in 1837; and New York medical college in 1851; each of which has an excellent edifice, and is well furnished with a library and cabinet. There are two theological seminaries,—the Episcopal, founded in 1817, and richly endowed; and the Union (Presbyterian), founded in 1836,—each possessing a large and very valuable library.

Institutions and libraries. The Cooper Institute, or the "Union," devoted to science and art, is an important establishment, founded by Mr Peter Cooper, at a cost of L.62,500, for the educational advancement of the youth and people of the city. Its handsome edifice, of freestone, six storeys high, and covering 20,000 square feet of ground, is unusually substantial, and fireproof. The American Institute, incorporated in 1829, for the encouragement of commerce, agriculture, and manufactures, has a building, containing a library of 8000 volumes and repository for models, in which weekly meetings are held for scientific objects; but this organization is especially noted for its annual exhibitions of national industry. The Mechanics' Institute has 5000 volumes, a good collection of philosophical and chemical apparatus, and regular courses of lectures. The Historical Society, founded in 1804; possesses an extremely valuable library of 25,000 volumes, and interesting collections, safely deposited in its fireproof edifice. It has published numerous volumes on American history. The Geographical and Statistical Society, founded in 1851, holds frequent meetings, and has about 8000 volumes. The

total number of volumes in the public libraries and institutions in 1855 was 336,290; of which, in the Astor Library, 80,000; Mercantile, 47,000; Society, 40,000, &c. The Astor Library was founded by John Jacob Astor, by his bequest of L.83,000, which directed that L.15,600 should be expended for a building, L.25,000 in a first outlay for books, and the residue, or over L.42,000, invested as a fund for the maintenance and increase of the library. The Mercantile Library Association, formed in 1820 for merchants' clerks and others, is one of the most useful organizations in the city, has 5100 regular members, and an annual revenue of over L.2000. Since 1854 it has occupied the building formerly known as the Astor Place Opera House.

The National Academy of Design, the chief art institution of America, was founded in 1826, since which time it has steadily advanced in influence and usefulness. It numbers among its academicians and associates nearly all the eminent artists of the city and vicinity. It supports free schools for the study of the antique and living models; possesses an extensive and valuable art library; makes annual exhibitions of original works by American and foreign painters and sculptors, &c. The New York Gallery of the Fine Arts is a permanent collection of American art, commenced a few years ago, containing many valuable works, but not yet accessible to the public, through want of a suitable and permanent gallery. The Dusseldorf Gallery is an admirable exhibition of the works of German painters, chiefly of the Dusseldorf school, in the building erected and formerly occupied by the late American Art Union. The Bryan Gallery of Christian Art is an extremely interesting and valuable collection of the works of the old masters. Several shops in Broadway, for the sale of oil-paintings, engravings, picture-frames, artists' materials, &c., keep up a rich display of works of art.

Theatres and other places of amusement are comparatively numerous and well patronized. Some of them are very large and elegant establishments. The building of the Academy of Music (or new opera house), completed in October 1854, has 4600 seats; it cost L.57,000, and its site L.12,500,—total, L.69,500. Among other permanent amusements are several companies of Ethiopian minstrels; and the changing attractions include an endless number of panoramic exhibitions, concerts, balls, &c.

The benevolent or charitable institutions of a public nature, founded and sustained by special associations, are highly creditable to the citizens. These are numerous, and some of them very extensive. The list embraces 9 hospitals, 3 infirmaries, 6 dispensaries, 7 homes for the relief of certain unfortunate classes, 4 homes for the aged and indigent, 2 houses of industry, besides the missionary establishments, and very many aid societies. In the upper part of the city are the institutions for the blind, deaf-and-dumb, and insane, each having spacious buildings, with beautiful grounds. There are extensive institutions for seamen on Staten Island, 6 miles from the Battery.

Most of the public institutions maintained by the city government are situated on the islands in the East River. The almshouse and its hospitals, lunatic asylum, workhouse, and city penitentiary, are on Blackwell's Island. The Nursery and various establishments for children, and the house of refuge, are on Randall's Island. Ward's Island is occupied with the hospitals, &c., under the charge of the Commissioners of Emigration.

New York contains many of the central offices and publication establishments of those great religious societies and denominations which embrace in their labours the whole country. Some of their printing-offices are among the largest in the city,—as those of the American Bible Society; American Tract Society; Methodist Book Concern; &c. In 1852 the Bible Society erected, at a cost of about L.62,500, a new building, six storeys high, and comprising

New York City. an entire block; part of it being occupied by offices of other societies.

Churches. Synopsis of the census returns on churches:—Number of churches in 1850, 214; in 1855, 252; aggregate accommodation in 1850, 219,098; in 1855, 234,730; value of church property in 1850, L.1,895,559; in 1855, L.2,519,319, consisting of L.2,270,916 as value of churches and lots, and L.248,403 as value of other real estate. Twenty-seven sects were mentioned in returns of 1855, from which are taken the following statistics of the chief denominations:—

Religious Denominations.	Church Edifices.		Usual Attendance.	Church Members.
	No.	Value.		
		L.		
Baptist.....	26	131,622	12,140	7,116
Congregational.....	9	60,935	4,175	905
Jews.....	10	36,894	3,825	1,953
Methodist Episcopal.....	33	121,414	15,090	8,878
Methodist African.....	6	25,000	3,005	1,668
Presbyterian (Old & New School).....	33	324,810	17,675	10,643
Presbyterian, Associate.....	6	78,748	3,700	1,708
Protestant Episcopal.....	43	700,844	21,850	9,006
Reformed Protes. Dutch.....	22	191,456	13,100	5,117
Roman Catholic.....	24	335,415	100,500	78,488

The most costly and conspicuous ecclesiastical edifices are those of the Protestant Episcopal denomination. Of these Trinity Church, built entirely of freestone, including the tower and spire, 264 feet high, cost L.83,000, and is the noblest building of Gothic architecture in America; and Grace Church, a very elaborate structure of white marble, cost L.42,000.

Croton Aqueduct. The Croton Aqueduct is the greatest and most important public work, and is not only superior in grandeur and costliness to anything of the kind on the globe in modern times, but to any work ever executed by a comparatively small community. In April 1835 the plan for its construction was ratified by the electors by a vote of 17,330 for, to 5963 against it. In July ensuing the surveys were commenced; in the spring of 1837 the work was fairly begun; and on the 14th October 1842 its completion was celebrated. Its cost to 1843 was L.2,386,158. The pond, now called Croton Lake, formed by the dam of Croton River, is 5 miles in length; the aqueduct from this dam to the distributing reservoir is 40½ miles; and the large mains from this reservoir, through the central part of the city to the Battery, add 4 miles, making the total length of the main conduit 50 miles. The aqueduct, built of stone, brick, and cement, has form and dimensions as follows:—The bottom is an inverted arch; the chord or span line is 6 feet 9 inches, and the versed sine 9 inches; the greatest interior width is 7 feet 5 inches; and the greatest depth 8 feet 5½ inches. For the first 5 miles the side walls have an extra height. It crosses Harlem River on a magnificent bridge, 1450 feet long, constructed of well-dressed granite, with 15 arches, the under side of which is 100 feet above high tide, completed in 1849, at a cost of L.200,710. Its general declivity per mile is, in its upper part, 13¼ inches, and in its lower part, 9 inches. The dam covers about 400 acres, and is available as a reservoir for 500,000,000 gallons above the level that would allow the aqueduct to discharge 35,000,000 gallons daily. The receiving reservoir, 5 miles from City Hall, contains an area of 35 acres, is divided into two equal parts, and has a capacity for 150,000,000 gallons. The distributing reservoir, 3 miles from City Hall, includes 4 acres, is also divided into two equal parts, and has capacity for 25,000,000 gallons. Its walls consist of an exterior and an interior wall, connected at every 10 feet by cross walls. At their base the thickness of the interior wall is 6 feet, of the exterior 4 feet, and the intermediate space is 14 feet; or 24 feet in all. Both walls

New York City. are carried 5 feet beneath the ground, and the exterior 44½ feet above it. The new reservoir, in the Central Park, begun in 1856 covers 97 acres; the cost of its construction is estimated at L.250,000; amount awarded for the land, L.147,500. The total length of street pipes laid to 31st December 1856 was 255 miles. The entire water receipts to that date amounted to L.1,103,823.

The fire department of the city is a powerful organization, effective in the preservation of life and property. The city is divided into eight fire districts; and in case of fire the alarm bells are struck according to the number of the district in which the fire exists. The name of the locality is signalled to the bell-ringers by telegraph. There are 46 fire-engine companies, 57 hose companies, and 13 hook and ladder companies; nearly all of which are well supplied with the necessary apparatus for efficient service. There are also 4 hydrant companies, whose duty it is to take charge of the hydrants at fires. The fire marshal's reports afford the following statements:—

Items returned.	June 1st to May 31st.		Decrease in 1855-6.
	1854-5.	1855-6.	
Number of fires.....	353	331	22
Alleged loss.....	L.288,994	L.192,335	L.96,656
Insurance.....	645,140	583,952	61,186
Amount paid.....	288,994	103,605	185,387

The permanent fund of the fire department, for the relief of widows and children of its deceased members, exceeds L.20,000; and the annual accounts of its payments for relief, have of late years ranged from L.3000 to L.4100.

Gas-light is supplied by two companies, of which we have the following statistics:—The New York Gas-Light Company, chartered in 1823, with a capital of L.208,000, supplies the district south of Grand Street; and in 1856 had about 130 miles of mains of various sizes, and lighted 3500 public lamps. The Manhattan Gas Company, chartered in 1833, with a capital of L.416,000, supplies the rest of the city; and in 1856 had 190 miles of mains, lighted 7300 street lamps (in 1850, 3797), and furnished gas to over 17,000 shops and dwellings. The following is a statement of the assessed valuation of these companies in 1856:—New York,—personal estate, L.70,286; real estate, L.121,248; total, L.191,534. Manhattan,—personal estate, L.274,570; real estate, L.180,666; total, L.455,236.

The city charter, as it now stands, according to the Act of Amendment of 14th April 1857, provides, that the government corporate name of the body politic shall, as formerly, be “the mayor, aldermen, and commonalty of the city of New York.” The legislative power is vested in the common council. This body consists of the Board of Aldermen and the Board of Councilmen. The former comprises 17 members, each elected for two years, 8 or 9 retiring annually. The Board of Councilmen consists of 24 members, 6 from each senatorial district, elected on general ticket. Both aldermen and councilmen must, at time of election, be residents of the districts from which elected. Executive power is vested in the mayor, who is elected for two years. There are 6 executive departments, the heads of which are appointed by the mayor, with approval of the Board of Aldermen. The various departments of city business are duly arranged according to statute. The expenses of the government have for many years been constantly increasing. During 1856 the total amount received into the treasury from all sources, except the sinking fund, was L.3,700,551; and the expenditure therefrom was L.3,589,312; showing an excess in receipts of L.111,239. The principal items in the accounts were of the sale of new city bonds, and the redemption of bonds due: The expenditures for the support of the city government proper were L.956,231. The permanent city debt

New
Zealand.

(chiefly for the Croton Aqueduct) on 1st January 1857, was L.2,964,712, and the amount then held by the commissioners of the sinking fund towards its payment was L.1,152,071, leaving as the outstanding debt unprovided for L.1,825,037. Amount received on account of the fund in 1856, L.253,723; interest paid on city stock in 1856, L.173,758; amount of funded debt redeemable from taxation, 1st January 1857, L.240,415; amount of city debt cancelled in 1856, L.117,926; in the early part of 1857 the sum of L.206,248 was paid on account of the aqueduct loans. The total operations of the city treasury for the years 1855 and 1856 were:—

Receipts in 1855, L.3,545,850.	In 1856, L.4,315,939.
Payments in 1855, 3,444,555.	In 1856, 4,236,276.

The total amount of tax (including the state tax) levied in each year, from 1851 to 1856 inclusive, was:—

In 1851 L. 609,233	In 1854 L.1,008,591
In 1852 703,816	In 1855 1,217,459
In 1853 1,066,173	In 1856 1,474,045

The value of the real estate owned by the city in February 1857 was L.9,002,511 (as estimated, being chiefly unproductive, at its cost price); of which the aqueduct L.3,370,247; parks, L.2,913,406; piers and bulkheads, L.1,213,122 (those used for commerce, L.842,915; for ferries, L.336,873; for corporation purposes, L.33,334); almshouses, L.354,166; schoolhouses, L.332,038; markets, L.245,164. (F. H.)

Situation
and area.

NEW ZEALAND consists of three islands of unequal size, situated in the South Pacific Ocean, between the parallels of 34. and 48. S. Lat., and of 161. and 179. E. Long. The northern island, called by the natives *Ea-hei-mauve* ("The Child of Mawe"), is of very irregular shape, the northern portion being a narrow peninsula, varying from 8 to 50 miles across, the centre widening to a breadth of 200 miles, and then decreasing to an average of 60 or 70 towards its southern extremity. Its length, as measured by a line drawn from Cape Maria Van Diemen to Cape Palliser, is 540, and the breadth between Cape Egmont and East Cape, 290 miles. The actual surface extent is not more than 48,710 square miles, or 31,174,400 acres. The middle island, called by the natives *Tavai Poenammoo* ("The Land of Green Talc"), extends from N. to S. about 470 miles; the breadth from E. to W. varies from 100 to 170 miles; and its area is computed at 72,072 square miles, or 46,126,080 acres. The southern island (called also *Stewart's Island*) is about 60 miles long, and 30 broad; its area being about 1800 square miles, or 1,152,000 acres. Thus the area of the three islands is estimated at 78,452,000 acres, being about 1,192,160 acres beyond the extent of the islands of Great Britain and Ireland. The names of New Ulster, New Munster, and New Leinster, attempted to be imposed upon these islands by the Colonial Office, have been disregarded by the British colonists, who desire for their adopted country a nomenclature more suitable to its future position among the nations of the Southern World. Zealandia, Austral Britain, and South Britain, have been proposed, as being more euphonious and descriptive, and it is probable that one of these will in due time be adopted by the general legislature.

Geological
formation.

That these islands are of volcanic origin, admits of no question. At no very distant period their whole area presented the appearance of a group of rocky islets, precipitous and barren, except in the gullies of the mountains. New Zealand largely participates in a general elevatory movement, extending from the southern pole over the whole Southern Hemisphere. Besides this, she has her own centres of volcanic action, some of which are yet in operation, gradually raising the level of the land; the proofs of which in the upheaving and increase of elevation are even now obvious to any intelligent traveller. Some of these changes

New
Zealand.

have been witnessed by the present generation. (Forbes.) These centres of volcanic action are supposed to be—(1.) at Otawa, near the Bay of Islands; (2.) the vicinity of Auckland; (3.) a range of country which may be defined by a line drawn from White or Sulphur Island to Rotorua, Lake Taupo, and Mount Tongariro, to Wanganui; (4.) the country around Wellington. (Taylor.) In the middle island the upheavement of the land is observable in a marked manner through the entire length of the western coast from Cape Farewell to Dusky Bay. Some of the most extraordinary changes in these regions have taken place within the last few years. More than half of the mountains of New Zealand are extinct volcanoes; a few are yet in partial action, as Waka-ari (White or Sulphur Island), Montohoro (Whale Island), Tongariro, and occasionally one of the Kaikora peaks. In the centre of the northern island, between Rotorua, Lake Taupo, and Mount Tongariro, the number of boiling mud pools, mud volcanoes, and openings emitting sulphureous steam, is astonishing. Some of them shoot up volumes of boiling water, like the geysers of Iceland, to which they are little, if at all, inferior. Earthquakes, as might be expected, occur occasionally; but their action appears now to be confined to the shores along Cook's Straits, and the western coasts of the middle island. The geological formation is simple, the rocks being erupted, metamorphic, trappean, and sedimentary, the latter all of them of tertiary origin, as proved by their imbedded fossils. (Forbes.)

New Zealand is eminently a mountainous country, level Face of the plains, though such there are of great extent, being the ex- country.— ception. The mountain ranges run parallel with the sea.— The moun- coast, generally from N.E. to S.W. In the northern island these ranges vary from 500 to 1500 feet in height, until tain ranges. they reach the centre of the island near Mount Pirongia, where the great central Rangitito chain commences, which, under the names of Ruahine and Tarahua, extends as far as the southern extremity. "This central mountain range throws off spurs or ridges of a very difficult mountainous country in various directions to the coast; the valleys between these ridges, generally mere gorges at the hills, become fertile and extensive plains near the coast; and form the channels of the Thames, the Waikato, the Mokau, the Wanganui, the Rangitiki, and other minor streams. These subsidiary mountain ridges or spurs, thrown from the main range, are for the most part, where roads have not been constructed across them, impassable even for horses; so that no overland communication, except for foot-passengers, can be considered as yet existing between the several principal settlements." (Sir George Grey.) Some of these mountains are very elevated, and are covered with perpetual snow. Pirongia is only 2500 feet high; but Tongariro is 6200 feet, and Ruapahu 9000 feet in height. Though not connected with any of the central or minor ranges, Mount Egmont or Taranaki stands about 30 miles from the sea, and rises to an elevation of nearly 9000 feet; it is distinguished by the perfect shape of its cone, covered with perpetual snow. The middle island has its northern shores skirted by a high crescent-shaped range of mountains, throwing out spurs towards the sea, and forming the sheltered harbours in which that locality abounds. This range unites with a great central range which runs through the island midway, and with another of yet greater elevation which skirts the western coast, and which approaches even to the very margin of the sea. Numerous streams, subject to sudden floods flow from these ranges. The highest peak in New Zealand, Mount Cook, which rises to about 13,000 feet above the level of the sea, is one of the mountains of this western range.

The appearance of the country generally is singularly Scenery. picturesque and attractive. "It may be called a wooded highland country, displaying some half dozen noble plains,

New Zealand.

and thousands of brook-watered valleys, dells, and dales. In combination of those great natural features which constitute the foundation of fine scenery, New Zealand is unsurpassed by any country in the world. She displays noble forests, snow-capped mountains, shooting up 10,000 feet from a sea of green, and wooded up to the line of snow; tracts of rolling champaign country, dells, valleys, rivers and rivulets innumerable; and 3000 miles of bay and ocean coast. The indigenous plants and trees being evergreen, there is no autumnal fall: the country is always verdant." (Hursthouse.) To the truth of this glowing picture we can bear testimony.

Soil.

The soil is generally fertile: the swamps may be easily drained, and will afford the best land to reward the labours and enterprise of future capitalists. There is perhaps as large a proportion of available land for agricultural and pastoral purposes as in the British Islands; and it must be kept in mind, that the grazing capabilities, as well as the results of husbandry in general, are fully equal to a similar extent of land in Britain. "Every English grain, grass, fruit, and flower attains full development and perfection. Surface and subsoil are generally light and porous: wet rapidly drains and percolates away." (Hursthouse.)

Climate.

The climate is undoubtedly one of the best in the world, and is peculiarly congenial to English constitutions and tastes. The summer is a little warmer than in England, and of longer duration; and winter, spring, and autumn, are much milder. Rain and heavy dews are frequent, but there are more fine days than in England; the high winds are perhaps the greatest inconvenience felt by strangers. Snow is never seen in the northern island, except on the mountain-tops; but there are occasional falls on the Canterbury and Otago plains in the middle island. Fogs and mists are rare, and thunder-storms less frequent than in England. As New Zealand is near our antipodes, the seasons are reversed, our summer months being winter months in the Southern Hemisphere. Some little difference of climate is caused by the difference of latitude between the northern and southern colonies; but this is less than might be expected. The mean temperature of the central part of New Zealand, as compared with that of London, is as follows:—New Zealand—spring 56°, summer 66°, autumn 58°, winter 52°; London—spring 49°, summer 62°, autumn 52°, winter 40. (Swainson; Hursthouse.)

Minerals.

From the peculiar geological formation of the country, it is probable that coal, copper, gold, and other metals, will be found in abundance; already accident, rather than scientific research, has discovered that the most important and valuable exist. Coal has been found near the North Cape, on the banks of the Waikato, at Mokau, at Massacre Bay, and in the Canterbury and Otago settlements. Gold-diggings are being worked at Coromandel, near Auckland, and at Aorere, near Nelson; and it is reported that this precious metal has been discovered in the Matoura River in the Otago colony. Copper is found at Kawau, the Great Barrier Island, Monganui, and at the Dun Mountain, near Nelson. Iron, in the form of pyrites and magnetic iron-sand, abounds; the latter especially near New Plymouth, and covers the shores for miles, yielding 50 per cent. of iron of the finest quality. Some of the rocks are powerfully magnetic. Lead and manganese have been met with near Auckland. The purest sulphur is abundant. Alum and nitre are found at Wanganui and near the Rotorua lakes: rock-salt near Mercury Bay. Various useful earths—fire-clay, pipe-clay, ochres, &c.—are common. Slate, marble, granite, sandstone, and freestone, are found in various parts; and limestone exists in many localities, and is of great purity. (Hursthouse.)

Vegetation.

The vegetation of New Zealand is remarkable. Six hundred and fifty distinct species of trees and plants are indigenous, of which scarcely twenty bear even a general

resemblance to any of our English plants; there are few annuals and flower-bearing plants, but a large number of tree-creeping parasitical plants, and of the beautiful fern and palm-tree family. The mode of growth in a New Zealand forest is different from anything in the Old World. "Thousands of tall columnar trees, 100 to 200 feet high, struggle up through a wilderness of underwood, their leafy heads so loaded with tufts of rushy parasites, that the true foliage is almost lost, while innumerable creepers coil round every stem, run up every limb, glide from head to head, and entwine the topmost boughs of a dozen trees in fifty Gordian knots. The underwood consists of these creepers, and of an equally dense growth of young saplings mixed with forest shrubs; and such is the closeness of the growth, that sun and air scarcely can penetrate." (Hursthouse.) The Kauri pine supplies splendid spars and masts. Other pines are useful for building purposes, furniture, &c. A resinous gum is an article of export. The root of the fern was formerly the chief vegetable food of the natives; and the *Phormium tenax* furnishes the New Zealand flax, which at some future period may be an important export.

The quadrupeds of New Zealand, previous to the arrival of Europeans, were the rat and the dog. Pigs were introduced by Captain Cook, and other valuable quadrupeds followed. There are about fifty varieties of land birds, and about a dozen of coast birds, of which the kiwi is the largest. The gigantic moa, 12 feet in height, is probably extinct, unless existing in the western ranges of the middle island. The rivers abound in small fish resembling the eel, grayling, whitebait, &c., of our rivers. The sea fish are numerous, but inferior to those of Europe for culinary purposes. The black whale frequents the coast from June to October. Seals are found in the remote south. Sharks are common on the coast. Cray-fish, oysters, cockles, and mussels are abundant. The insects are similar to those in England. The sand-fly is annoying to travellers in the summer. (Hunburn.) (For the natural history of New Zealand we must refer to the able treatise of the Rev. Robert Taylor, *Teika a Mawi*.)

By the New Zealand Constitution Act (1852), the three islands are divided into six provinces, three of which are the northern island, viz., Auckland, New Plymouth, and Wellington; the remaining three are in the middle island, viz., Nelson, Canterbury, and Otago. The southern island forms an appendage to the latter colony. Although a very small portion of the island thus geographically appropriated is occupied by the European settlers, this division is a convenient one for the purpose of a more particular description of the present condition of the British colonies in New Zealand.

Auckland, the northern province, is about 400 miles in length, 200 in breadth, with a coast-line of 800 miles, and an area of about 16,000,000 acres. It possesses the only navigable rivers of any importance to be found in the island, namely, the Waikato, with its tributary the Waipa; the Thames; the Piako; the Kaipara, with its tributary the Wairoa; and the Hokianga. There are also several smaller streams, which at their mouths form suitable harbours for ships of from 400 to 500 tons, and are navigable for boats of 20 tons from 7 to 10 miles. Larger harbours are numerous. The Waitemata (upon which Auckland stands), on the east coast, nearly joins the Manukau harbour, on the west coast, from which a narrow isthmus of 6 miles separates it. The Waikato, Kawhia, Whaingaroa, Kaipara, Hokianga, Wangaroa, Bay of Islands, Mercury Bay, Tauranga Bay, Maketu, Hicks Bay, Turanga or Poverty Bay, are also respectable harbours, with others of less note. This very extensive water communication, so important to infant settlements, especially in a country where roads are few, and carriage by land almost impossible without them, has led to the largest amount of European immigrants being

New Zealand.

New Zealand.

settled in this part of New Zealand, without any adventurous help from colonizing companies. About one-twelfth of the sixteen millions of acres has been purchased of the natives by the colonial government. The chief town, Auckland, situated on the south side of the Waitemata harbour, and, like another Corinth, commanding the narrow isthmus of Manukau, is one of the finest commercial sites in New Zealand, "the centre of a network of marine highways, a youthful antipodal Venice, surrounded by natural canals." (Hursthouse.) Being built upon hills, there are few level streets; but the houses are generally respectable. The public buildings, churches, chapels, &c., are equal to those in any town of the same size in the mother country. The Church of England and the Wesleyans have respectable schools for the education of the European population, and institutions for the training of the native youth in the vicinity. Two weekly English newspapers are published, and one in the native (Maori) language. The population is about 8000. Near to Auckland are the military pensioner villages of Panmure, Howick, Oneunga, and Otahu, all within a range of 6 or 10 miles, and connected with Auckland by well-made roads. Russell, in the Bay of Islands, which was once intended for the capital, is but a very small town. Besides, there are various coast settlements, such as Coromandel, Otea, Wangari, Wangaroa, Monganui, Hokianga, Whaingaroa, Kawhia, and Tauranga, which have from 50 to 100 pioneer settlers, the nucleus of future city populations. The principal lakes are Rotorua, Tarawera, Rotomahana, and Taupo, in the vicinity of which are found the hot springs, mud volcanoes, &c., to which reference has already been made. In the general fertility of the soil, and in the amount of available land for cultivation, Auckland is fully equal, if not superior, to the other provinces in the northern island, although in the peninsula north of the Waitemata there is much poor and swampy land. The gold field at Coromandel, and the copper-works at the Great Barrier Island and Kawau, are now partially abandoned for want of labour; but the mineral treasures of this province will at some future period contribute largely to its resources. The census of 1855 gave a population of 11,919 Europeans; but the estimate for 1857 is about 15,000, to which we must add 35,000 natives, who contribute their fair share to the industrial resources of the colony.

New Plymouth.

New Plymouth, called also *Taranaki*, is the smallest of the six provinces, and is situated on the west coast, between Auckland and Wellington. It has a coast-line of 150 miles, and is about 100 miles long by 50 broad, with an area of about 3,000,000 acres, of which not quite a fiftieth part is yet in the possession of the colonists. It has no navigable rivers, but many small streams, as the Mokau, Oneiro, Waitera, Manawapo, and Patea, which are occasionally entered by small vessels. The roadstead near the town of New Plymouth affords great facilities for the loading and unloading of the largest vessels, and there is no doubt but that by the outlay of a moderate sum of money a good harbour might be formed at this place, for which there are peculiar natural facilities. Around the town, or rather township, of New Plymouth, the European population is mainly concentrated within a radius of 10 miles. The soil is peculiarly fertile; so that this portion of the island is by common consent termed the "Garden of New Zealand." The country near the sea is open and undulating; beyond, at some distance, it is forest, containing excellent timber. Mount Egmont, covered with perpetual snow, gives a peculiar character to the scenery. The unwillingness of the natives to sell their lands has hitherto retarded the progress of this settlement, by preventing a larger accession of immigrants. In 1855 the European population was 2113, and the estimate for 1857 was 3000. This small community, intellectually and morally, is perhaps one of the most select and respectable in the world—not even

New Zealand.

excepting the most favoured portions of the mother country. The native population is about 8000. One weekly paper is published. When the colonial funds admit of the expense requisite for the formation of a harbour, and when the native title has been more extensively extinguished by purchase, this portion of New Zealand will offer irresistible attractions to settlers from the mother country.

Wellington is the southern province of the northern Wellington island, 200 miles long, 100 broad, with a coast-line of 500 miles, and an area of 12,000,000 acres, of which about one-third has been purchased of the natives for the purpose of European settlement. The land near and within 20 miles of the principal harbour (Port Nicholson) is mostly mountainous, densely timbered, broken by steep ravines, and most unfit for cultivation; but the valleys of the Hutt, Wairarapa, Wanganui, Rangatiki, Manawatu, and sundry adjacent portions, are admirably adapted for agricultural purposes. The vicinity of Hawkes Bay (Ahuriri) has also much good land; and from this point there is a communication across the island to Manawatu, and southerly to the Wairarapa valley. Three of the rivers may be called semi-navigable, as they may be entered by vessels of small tonnage—the Wanganui, the Rangatiki, and Manawatu. The harbour of Porirua is available for small vessels, and this harbour and the available country to the north, in the basins of the Manawatu, Rangatiki, and Wanganui rivers, are connected with the town of Wellington (Port Nicholson) and the Hutt River district by an excellent road, which winds round the spurs of the Tarirua range. A good road along the bay connects Wellington with the Hutt River valley; and another road now forming will lay open the whole of the Wairarapa valley, and afford easy means of intercourse with the capital. In no part of New Zealand has so much been done to overcome formidable natural obstacles by means of good roads. Wellington, the capital, is situated on a beautiful bay opening into Cook's Straits, which forms the harbour of Port Nicholson, and which is 6 miles across, surrounded by hills of great elevation, and affording a shelter for large vessels. The town, built mainly of wood, stands on two level spaces on the west and south sides of the harbour, and rises in terraces from the margin of the bay, which gives it a most picturesque appearance from the sea. The bay and scenery around has been compared to that of Naples. Occasional earthquakes, which have, however, ceased to be dreaded since the houses have been built of wood, and high winds, are the main drawbacks to this locality. Its central position on the great marine highway of Cook's Straits is the greatest advantage of Wellington, which must secure for it an important rank among the future depôts of New Zealand; especially as it possesses, next to Auckland, the best portion of the northern island. Its population in 1857 was probably 5000. The other townships are, a rural settlement in the Hutt valley, a small town at Wanganui, Port Napier at Ahuriri (Hawkes Bay), and the native mission village of the Church of England at Otaki, remarkable for its beautiful church, of native workmanship. The province probably contains 12,000 Europeans and 15,000 native inhabitants. Two weekly papers are published at Wellington.

Nelson is the northern province of the middle island, and is 150 miles long, 140 broad (with a coast-line of 500 miles), and an estimated area of 15,000,000 acres, all of which are virtually open for settlement, as the native population scarcely amounts to 1000. The climate is comparatively serene and dry, and more equable than in any of the other provinces. It possesses great mineral wealth in coal, copper, and gold. Between D'Urville Island and Cloudy Bay are a large number of noble harbours opening into Cook's Straits, of which Queen Charlotte's Sound and Pelorus Bay are the principal; but the wooded hills rise so abruptly that it has been stated, though perhaps with some

New
Zealand.

exaggeration, that there is scarcely a thousand acres of land fit for the plough to be found along their margins. The valleys of the Waimea and Motueka, of Blind Bay, Massacre Bay, and Cloudy Bay (Wairau), afford, however, ample room for the agriculturist and grazier. The Grey and Butter rivers, on the west coast, are now found to be available as ports, and to possess in their vicinity much valuable land—a pleasing exception to the general disparaging character which has been given to the capabilities of the west coast of the middle island. Nelson, the only town, is situated at the bottom of Blind Bay, and possesses a small but safe harbour, 50 miles away from the turbulent winds of Cook's Straits. It is sheltered by a range of hills from the southern blasts, and enjoys a climate equable and serene beyond any other locality. The Dun Mountain, within a mile of Nelson, contains treasures of copper yet to be developed. The European population of the colony, which amounted in 1855 to about 6000, and which was supposed to be, in 1857, 9000, is mainly located around Nelson, or within a moderate distance. There is a weekly paper published at Nelson. A new township has been formed at the harbour of Waitohi or Newton Bay, a south-eastern branch of Queen Charlotte's Sound; this is intended to be a port for the produce of Wairau (Cloudy Bay), and of the Awatere plains, to which district a road is now being formed of 12 miles through a nearly level valley. Other paths are being discovered through the mountain-passes, by means of which communication will be facilitated with the various settlements in the Nelson province, and with those in the adjacent province of Canterbury. Two lakes are connected with the Butter River (Rotorua and Rotuiti); but as yet the interior of the middle island has not been explored. The gold-diggings at Aorere (Motueka River) are now exciting much attention, from their productiveness; but their main value to this province will be the additional incentive given to emigration to it.

Canter-
bury.

Canterbury is the central province of the middle island, and is 200 miles long by 100 broad, with a coast-line of 500 miles, and an area of about 14,000,000 acres, all of which are available for settlement, as the native population is not above 500. The western portion of this province is probably rugged and scarcely accessible; the centre is occupied by mountainous ranges not yet explored. A vast elevated plain of 4,000,000 acres extends from the foot of these central ranges, gradually descending 40 miles to the heights above Port Victoria (called also Port Cooper). This plain is watered by more than twenty rivers. The portion nearest the west coast consists of a deep border of fine cattle-grazing and loamy agricultural land; but the great inland portion is a true pastoral country, covered with a perpetual herbage of grasses and dwarf shrubs, and admirably suited for the breeding and depasturage of sheep, horses, and cattle. The absence of wood is remarkable, but there is plenty in Banks' Peninsula and at the foot of the central highlands. About fifty small rivers discharge themselves into the sea on the east coast of this province, of which the mouths of the Ashley, Courtney, and Avon are navigable for a short distance by very small boats. A remarkable feature in this province is Banks' Peninsula, which protrudes from the east coast, and consists of a pile of densely-wooded volcanic hills, among which the principal harbours of the colony are found,—viz., Port Victoria (or Cooper), Port Levy, Pigeon Bay, and Akaroa Harbour. Lyttleton, the post-town of the colony, is situated upon Port Victoria, at the foot of the heights which lead to the great plain. Population from 2000 to 3000. A good road is being made up the heights, to connect Lyttleton with Christchurch, the capital, which stands on the Avon, on the border of the great plain. Population between 2000 and 3000. There are small settlements on the other harbours of the peninsula. Akaroa was the site of the French settlement formed

New
Zealand.

in 1840, and yet retains many of its original settlers. This colony was originally designed for members of the Church of England, and possesses a large number of the clergy of that church, and educational institutions conducted by them. There are also Wesleyan and Presbyterian churches, as the exclusive principle has been wisely abandoned. Great facilities are offered to small farmers and graziers, and the tide of emigration is rapidly flowing in this direction. The European population in 1857 was supposed to be not less than 7000, who, as a matter of course, have their weekly journal.

Otago is the southern province of the middle island, and *Otago* includes the whole of the southern or Stewart's Island. It is 150 miles long, 200 broad (with a coast-line of 500 miles), and an area (including Stewart's Island) of about 18,000,000 acres, the whole of which is available for settlement, as the natives do not exceed 500 in number. The south-western coast is remarkable for its thirteen harbours, like so many breaches in the sea-wall of this otherwise iron-bound coast, and which run in a N.N.E. and S.S.W. direction from six to twenty miles inland. The land around these harbours rises almost perpendicularly from the water's edge, and is covered with trees suitable for all purposes. The depth of water also is remarkable, as soundings can rarely be obtained under from 80 to 100 fathoms. The ports on the east coast are Moerangi, Otago, and Molyneux Bay. Stewart's Island is well wooded, contains many excellent harbours, of which Port Pegasus is the principal, and is partially colonized by various little communities of tens and twenties of old whalers, half-castes, and natives. The European population of the province, about 4000, chiefly Scotch, is settled on the east coast, in or near the following settlements:—Dunedin, the capital, stands at the head of an arm of the sea, which is only navigable for large ships as far as Port Chalmers; population about 2000. Port Chalmers is a rising seaport. Invercargill, the most recent settlement, is situated on the Bluff in Foveaux Straits, in a central position between the Bluff harbour and the New River, a fine stream, navigable for 20 miles. The lofty mountain ranges towards the west coast, and the three large lakes which are reported to exist in the interior, have not yet been explored. From these ranges to the sea-coast on the east the province consists for the most part of splendid plains diversified with hill and dale, as if to suit our notions of beauty, and available for all grazing and agricultural purposes. The climate is bracing and invigorating, yet temperate. This important province has the advantage of being a few days nearer England than any other part of New Zealand. Dunedin has, like the other colonial capitals, its weekly journal. It was originally the settlement of the Free Church of Scotland, and complaints are made of the somewhat exclusive tone of feeling prevalent in society, which is annoying to settlers from other countries and belonging to other churches; but this grievance, if it does exist at all, must vanish with the increase and spread of the population, while the industry, moral worth, and enterprise of the Scottish population must insure for this colony a high place among the political communities of New Zealand.

It will be seen from the above sketch of the various colonies, that while there is ample room in the northern island for emigrants, the whole of the middle and southern islands are open for settlement, without any possible interference with native rights. And when we consider the climate, soil, harbours, and other available capabilities of these invaluable islands, which only require a large European population for their speedy and full development, we cannot but augur favourably as to the position which New Zealand will at some future period occupy in the history of the world.

The population of European race in New Zealand is

New Zealand. Statistics, population, &c.

estimated by Hursthouse, for the year 1857, at 50,000, which is perhaps somewhat beyond the actual number; add to these 60,000 natives, and the entire population will be found not to exceed 100,000,—a scanty supply for a land which is as capable as the British Islands of supporting nearly thirty millions of people in all the comfort and luxury of civilized life.

Districts.	Europeans.	Natives.	Acres cultivated.	Sheep.	Cattle.	Horses.	Pigs.
Auckland.....	15,000	35,000	50,000	50,000	20,000	2,800	7,000

Trade, marine.

The exports of the New Zealand colonies consist of provisions and timber to the neighbouring Australian colonies, and of wool, tallow, spars, flax, gums, copper ore, &c., to the mother country. The estimated value of these exports for 1857 is L.400,000, while the imports may be calculated at L.600,000; part of the latter consisting of property belonging to emigrants from Europe, and forming part of their capital stock. The welfare of New Zealand depends mainly upon agricultural pursuits, as whaling stations have ceased to be profitable, and the copper mines have not succeeded, from the scarcity of labour. A taste for maritime pursuits seems to be rapidly developing, if we may judge from the statistics of the shipping the property of New Zealand, as well as that employed in the foreign trade. About 700 vessels of all sizes belong to the colonists, the tonnage of which is 20,000, and most of them are of colonial build. The foreign trade employs 400 vessels, with a tonnage of 250,000. Steam communication is maintained between Sydney and Auckland, and subordinate lines are soon to ply between Auckland and the principal ports of the islands. The adoption of the Panama route for the Australian mail service to and from England would bring New Zealand within forty days of the mother country.

The value of land varies in every colony, but the minimum price of wild land may be stated as ranging from 5s. to 60s. the acre. Large tracts of land, especially in the middle island, may be occupied, at fixed moderate rents, for grazing purposes.

Political government.

The present constitution of New Zealand, adopted by Sir J. Pakington, the colonial secretary under Earl Derby's administration, received the sanction of the British Parliament in the session of 1852. A plan of government, on the principle of double election, framed by Earl Grey, the colonial secretary of a previous administration, had met with almost universal disapprobation, and had been withdrawn without having had a trial. The main provisions of the plan of government now in operation are as follows:—

(1.) The six provinces were formed into distinct corporate bodies, with privileges far beyond those enjoyed by ordinary municipalities; so that the term "government" may be with propriety applied to them. Each of these was empowered to elect a superintendent and provincial council, the latter not to consist of fewer than nine members, but capable of being enlarged at the discretion of the governor-general. The superintendent and council are elected for a period of four years, by a suffrage which is almost universal, the qualifications being small, and the possession of property being a common thing in new colonies. The governor-general may disallow the election of any superintendent, and may dissolve the provincial council at pleasure, and may also disallow any bill passed by them within three months; but if allowed by him, it cannot be annulled by the imperial government in England. The superintendent may summon and prorogue his council; but there must be:

one session at least in each year. These provincial councils are prohibited from interfering with general legislation affecting the whole colony; as the customs, civil or common law, currency, weights and measures, post-office, bankruptcy, lighthouses, harbour dues, marriage, inheritance, &c.

New Zealand.

(2.) The government of the whole colony of New Zealand to be vested in a governor appointed by the crown, with a moderate civil list, secured by act of Parliament; and also in a General Assembly, consisting of a Legislative Council and House of Representatives, meeting in annual session in Auckland and legislating for the entire colony, with the exception of matters of purely local interest, which are left to the provincial councils. The Legislative Council consists at present of 15 members, nominated for life by the governor. The House of Representatives consists of 36 members elected for five years, by a suffrage similar to that of the electors of the provincial councils. The House can be dismissed by the governor at pleasure.

(3.) In the general government, and also in the provincial superintendencies, the principles of responsible government are carried out as in England. The majorities create and turn out administrations, and each acceptance of office by a member is followed by a necessity of a re-election.

(4.) To avoid the interference of the British Colonial Office in the land question, the control of the public lands in each province has been since vested by the General Assembly in the respective provincial councils; the legislation of which minor bodies, if confirmed by the governor-general, is not liable to be disallowed by the government in England. This appears to be a palpable evasion of the plain meaning of the act of Parliament by which the new constitution was established in New Zealand.

Making due allowance for the natural and inevitable difficulties attendant upon the introduction of a new system of government into a new country, and among a scattered population, it must be admitted that the constitution (cumbersome and complex as it may appear for a population which, in 1853, scarcely exceeded 30,000, and which now, in 1857, does not amount to 50,000) on the whole works well. Local self-government is so desirable for young colonies, that any inconvenience and cost is a small price for the inhabitants to pay for the privilege of developing their own resources and managing their own affairs, unchecked by a distant executive and legislature, necessarily ill acquainted with their wants and capabilities. These provincial assemblies and administrations have called forth much local patriotism, and have developed much administrative talent; and it must be remarked that the colonists of New Zealand are, a large proportion of them, from the more educated and respectable classes of the mother country. A time may come when increased facilities of communication may render it desirable to consolidate the local superintendencies, and merge their powers in that of the general government; but this and other changes may be left to the colonists themselves, who are the best judges of their own legislative necessities.

It is difficult to ascertain the exact amount of the annual Revenue revenue and expenditure of the seven exchequers of New and Zealand (viz., the six colonies and the general government). Hursthouse gives the expenditure and revenue of 1856 at L.270,000; one-half of the expenditure being for purchase of land and public works. The revenue for 1857 arising from land sales, customs, &c., is estimated by the same writer at L.300,000. A loan of L.500,000 has been guaranteed by the British Parliament for New Zealand, to enable the general government to pay off the debt claimed by the New Zealand Company, and for emigration and other purposes. The government claim the right of pre-emption in the case of land, so that no land can be sold by natives except to the crown; this land is sold again at a much higher price to the European settler. It is questioned

New Zealand.

whether this mode of purchase has not been on the whole injurious, as the natives are becoming more and more unwilling to part with land in large portions, but would be ready to sell in small parcels to individual purchasers.

The Maori (native) population.

Some account of the native population will be found in the article AUSTRALASIA, section viii., vol. iv. We may here add some further information respecting this interesting people, now rapidly progressing from savage life into civilization. It is obvious that the Maori belongs physically, and by the structure of his language, to the light-coloured race of the Pacific Ocean, which is found spread over the islands for a distance of 6000 miles (from the Sandwich Islands to New Zealand). This race is supposed to be of Malayan origin by some; while others suppose the ancient Mexicans to have been the parent stock of the Pacific islanders. We require a more perfect acquaintance with the languages of the Eastern Archipelago in order to arrive at any definite conclusion respecting the ethnology of this part of the world. Certain it is that the progenitors of the Maori came from Hawaii and Tanai, two of the Sandwich Islands, called in the New Zealand dialect Hawaiki and Tawai, about 500 years ago. The names of thirteen canoes of the leading chiefs, and of the articles brought in each canoe have been preserved, with the additional information, that the emigration came by the way of Tahiti and Easter Island (Waiho). "The New Zealanders are decidedly a mixed race: some have woolly hair, others brown or flaxen; some are many shades darker than others. The peculiar features of the Tartar are also very common; the oblique eye, the yellow countenance, the remarkable depression of the space between the eyes, so that there is no rise in the nose, seem clearly to indicate that some portion of the race is of Chinese or Japanese descent." (Taylor.) This view is confirmed by the fact of a bell, with characters similar to Japanese, being found in the district of Wangaree in 1839. It is supposed that, as a race, the Maori have degenerated from their ancestors, who, at Easter Island, have left monuments of bygone skill in the arts, and who, up to the discovery of the islands by Captain Cook, possessed double canoes of superior build to any now found among them. The superior houses of the Maori, and the art of weaving, may have been introduced by these Chinese or Japanese emigrants accidentally thrown upon their coasts. Native traditions, mixed up with much fable, seem to indicate the existence of an aboriginal population, which was either destroyed or amalgamated with the Maori emigrants. It is remarkable that, like most colonists, while preserving the religious traditions of their ancestors, the political bond of union was broken among themselves. Split into innumerable families and tribes, each having its own head, and independent of the rest, the history of the Maori is one of discord, war, and blood. It is reported that once a large temple called the Whare-Kura existed, in which all the tribes met for worship, for council, and for the settlement of disputes. This sacred locality, at first a grand place of union, became the source of discord; the chiefs quarrelled, fought, and at last burnt the building; and from that period there has been no union; one tribe has ever been opposed to the other. At present Taylor enumerates twenty-three principal tribes yet intact, besides fragments of others nearly extinct. The power of the chiefs rests upon their birth and personal character. No great chief, like those found in the Polynesian islands, exercises regal power. By the Tapu, which is a powerful engine of control possessed by the chiefs in New Zealand, as well as in the other islands of the Pacific, the common people were effectually restrained, sometimes for good, and also for evil. It consisted in making any person, place, or thing sacred for a longer or shorter period, and was in fact a religious observance established for political purposes. (Taylor.) With a philosophical cosmogony and a poetical mythology, they had no knowledge of a Supreme Being, but believed in a multitude of divine beings, the creators of various natural objects; and these were confused and mixed up with the spirits of their ancestors. Thus, like the Greek heroes of the mythical period, most distinguished persons among the Maori trace up their ancestry to a deity (Atua). One of these (Maui) is said to have fished up New Zealand (the universal tradition of the Polynesian races in reference to their several islands). Prayer, in our sense of the term, formed no part of the religion of the people: the *karakia*, which we translate "prayer," is rather a spell or incantation to compel the gods to be obedient to their wishes. These were accompanied by sacrifices and offerings. Image-worship was confined to one locality, and was offered to the deity, who was supposed to be present in the idol. The high chiefs (*Ariki*) and priests (*Tohunga*) were supposed at all times to be able to hold visible intercourse with the gods. The belief in the power of bewitching, as being possessed by every one, was universal, and kept the native mind in bondage. Great attention was paid to the burial of the dead, for the sake of the spirit which survived the dissolution of the body. "The prevailing

New Zealand.

idea of the abode of spirits was, that they went to the Reinga, which is another name for Po or Hades: the word Reinga literally means a "leaping place." The spirits were supposed to travel to the North Cape, or land's end, and there, passing along a long, narrow ledge of rock, they leaped down upon a flat stone, and thence slinging themselves into the water by some long sea-weed, they entered Po, the Reinga being the passage to it. It was supposed that there were several compartments in Hades, the lowest being the worst, having no light or food, and there the spirits were thought gradually to pine away, and to be finally annihilated." (Taylor.)

Before the general reception of Christianity the natives resided in large fortified stockades, commonly erected on the summit of a steep hill, or on a peninsula, &c.: these are called *pahs*. The strong high fence of these *pahs* presents no mean obstacle to foes not possessed of artillery. Within the *pah* are numerous subdivisions and lower fences, communicating with each other by means of stiles: in each court a house, cart-house, and store for food: the houses partly sunk in the ground, with a gable roof, and a portico or verandah, where the occupants generally sit. The post in the middle of the house, which supports the ridge-pole, has its lower part carved into the form of a human figure representing the founder of the family; and the same figure is generally found to surmount the gable end of the house. The inner chamber or sleeping-place is heated like an oven, and is offensively so for Europeans; but the natives enjoy it the more, being huddled together almost naked for the whole night. Now the *pahs* are generally deserted, especially those in inconvenient positions; the stockades are left to waste away; and the population is found in villages and solitary farms, as in our own country. Slavery scarcely exists now, having yielded to the power of Christianity; though the social distinction yet subsists, as it does even in more civilized communities. The pride of birth is found in perfection in New Zealand, for "very little is thought of a chief who cannot count back some twenty or thirty generations, and the high families carry theirs back even to the beginning of all things. I was once very much amused, in obtaining a tradition of this kind, beginning with '*from the nothing the something*,' which went on gradually introducing name after name, and at last terminating with that of the speaker." (Taylor.) To assist the memory, each family has a carved board, which serves as a sort of genealogical table, and the children were from this taught the names of their ancestors. Polygamy, especially among the chiefs, was common before the conversion of the natives to Christianity. Infanticide was not unusual, and there was a great want of natural affection, with much show of it, if we may judge of the ceremonious salutations—the nose-rubbing, and the *tangi*, or weeping. War was carried on most barbarously; the defeated party, if not slain, were reduced to slavery. Cannibalism was universal, but was said to be of recent origin, and arose, not from hunger, but from a deep feeling of revenge. Now the very mention of this horrid custom is hateful to the Maori; such a change has Christianity effected in public opinion, as well as in national usages, within the space of one short generation. A large number of songs, proverbs, and fables are known to the old men, and formed the oral literature of the people before the missionaries introduced letters and a new order of ideas. These have been preserved by Sir George Grey and by the Rev. Richard Taylor, just in time, as in another generation they would have been lost. The native dress, made of the flax plant, and the practice of tattooing, and many other peculiarities of the preceding generation, are now rapidly passing away; and future travellers will not be able to recognise the Maori described in the writings of visitants of twenty or thirty years ago. The land tenure of the Maori people throws some light upon their economical condition while comparatively savage and uninfluenced by European civilization, and is also of importance in its bearings upon the future relationships of our colonial government with the native tribes. No one has so fully and satisfactorily described these as the Rev. Richard Taylor:—"Land is held in three ways by the natives: either by the entire tribe, by some family of it, or by a single individual. The common rights of a tribe are often very extensive. These generally apply to waste lands or forests, and convey to each individual of the tribe the right of hunting and fishing over those parts. By intermarriages several tribes are sometimes thus entitled; but if such land be sold, it is nominally said to belong to the principal chief or chiefs of the tribe; they are the parties with whom the treaty is made, and to them the payment is given, which is, however, a nominal honour, the money being equitably divided amongst all who are entitled to a portion, the seller rarely retaining anything for himself. The same may be said of that which is claimed by families: private rights to land are very rare. The eel-cuts are held in the same way. These are drains made from lakes or swamps, with weirs at the outlet to catch the fish, which flow out in great quantities during the floods."

New Zealand.

It appears that all the descendants of the first possessor of a piece of land or eel-cut possess a claim to a share of the property, and that the stones placed as landmarks are as sacred as the *dit termini* of the ancient Romans. The property of the native tribes in their lands having been acknowledged and strictly respected by the British government, the existence of the Maori is secured from the degradation which has befallen the natives of many of our colonial possessions. Yet for some time after the commencement of regular intercourse with Europeans, the population rapidly declined, owing, perhaps, in some measure, though not entirely, to the introduction of European diseases, and the evils attending the transition state of the population from their previous habits to those of Europeans. For instance, the warm flax dress, impervious to the rain, was abandoned for the shirt and habiliments of the Europeans. This mode of dress—worn in all weathers, and by night as well as by day, without a change, and when wet, dried upon the body of the wearer—was followed by a great increase in consumptive complaints: add to this the introduction of fire-arms, which was at first attended with a large increase in the number slaughtered in war, as their possession was confined to a few tribes who took advantage to revenge themselves upon their enemies. At present there is a great disparity in the number of the sexes,—the women being few in number compared with the men; and the children are yet fewer in proportion, say 75 females and 45 children to every 100 adult males. We suspect that this diminution of population is incident to savage tribes on coming in contact with a more civilized people, and that after a time this diminution may cease, and a gradual increase take place. Indeed, it is the opinion of intelligent missionaries that the population is beginning to increase, and that in some parts of New Zealand—Taranaki, for instance—the number of births already exceeds the number of deaths.

Missionary labours.

The present advanced condition of the Maori population is owing mainly to the indefatigable and praiseworthy exertions of the missionaries. The Rev. Samuel Marsden, the colonial chaplain in New South Wales, established the first mission of the Church of England in New Zealand in December 1814; and in 1821 the first Wesleyan mission station was founded by the Rev. Samuel Leigh. For many years the field appeared the most unpromising, and no impression appeared to be made upon the native mind; but at last complete success has followed the efforts made, and now all the inhabitants of New Zealand are nominally Christian. Cannibalism, polygamy, slavery, and other abominations of heathenism have disappeared. Life and property are perhaps as safe in New Zealand as in any country in the world. The missionaries have introduced the plough and all the useful arts of civilized life; they have reduced the language to writing, compiled grammars and dictionaries, and translated the Word of God and other works into the language of the Maori population, most of whom can now read and write. The progress of the natives in civilization has far surpassed the most sanguine anticipations of those who are competent to estimate the obstacles which have to be overcome in the transition of a whole people from savage customs to the decencies and comforts of civilized life. As agriculturists and traders, the Maori people occupy respectable positions; some of their farms are highly creditable to them; and in bargain-making they manifest something of the caution and shrewdness of the Scottish character. Many of the chiefs are owners of steam flour-mills, and others possess small trading-vessels; some are shareholders in colonial banks; and many, both of the chiefs and people, after selling portions of their land to the colonial government, have shown their appreciation of the security of an English title, and their faith in the additional value which will be given to it by European industry, by becoming purchasers of allotments for their own use. In addition to the European missionaries who labour among them, almost every village has its native teacher and common school; and there is an institution for training native teachers at Turanga. Among the special friends of the Maori race we may mention the late governor, Sir George Grey, and that remarkable man, Bishop Selwyn. The Wesleyans have an institution at the "Three Kings," near Auckland, for the training of Maori youths, which deservedly stands high, and, together with other kindred institutions, is exerting an important influence upon the more respectable class of the native population. There are other missions of minor importance carried on by the Roman Catholics and by a German society.

The future of the Maori population.

The future of the Maori population is contemplated by philanthropists with intense interest. If the legislation of the British colonies of New Zealand be in keeping with the general character of the colonists, and of the religion which they profess, the Maori will, in one or two generations, become thoroughly identified in interests, views, and feelings with the English population. It is, however, very desirable that means should be adopted at once to give the chiefs and more respectable wealthy and educated natives a definite political and social position in connection with the local and general legislatures. Much uneasiness is already felt by the

more intelligent natives at the fact of their political nothingness; and one very large meeting was held last year (1857) to consider the propriety of electing a king as the representative of the Maori people. This proposal has for the present been negatived; but the feeling which prompted it remains, and must be grappled with. The Rev. Robert Taylor, an experienced missionary, and Charles Hursthouse, Esq., a well-known colonist and writer on New Zealand, contemplating this difficulty from very different points of view, agree in recommending that a certain number of the high chiefs should have seats in the General Assembly, and that they should be placed in the magistracy of their respective districts, with suitable salaries. We have no doubt that in all questions affecting the local interests of their respective districts and people, they would be valuable senators, legislators, and magistrates. It is gratifying to know that the feeling among the European population of New Zealand towards the aborigines is most friendly; and no plans are so popular, or meet with more general support, than those which have the advancement of native interests for their object.

New Zealand.

The history of the discovery of these islands, and of History of European intercourse up to the year 1809, will be found in the article AUSTRALASIA, § viii., vol. iv. The increase of the whale fishery in the South Pacific Ocean led to the settlement of numerous deserters from whale ships in various parts of New Zealand. This was followed by the establishment of whaling stations on the shores, which afforded opportunities for the introduction of many of the less reputable of the convict class from New South Wales. In the wake of these followed many reputable traders and settlers engaged in the timber trade, &c. A large European population was thus planted principally in the northern part of the northern island, uncontrolled by any legitimate authority, and amenable to no law. Besides these irregular settlements, there were a number of mission villages belonging to the Church of England and the Wesleyan missionary societies, exercising a measure of influence upon the natives and more respectable Europeans, and occasionally brought into trying circumstances through the conduct of the lawless portion of the European population, as well as from the violence and cupidity of the natives. The measures adopted at intervals by the imperial government, and by the colonial government of New South Wales, were not only partial and calculated rather to irritate than repress crime, but proceeded on assumptions of a contradictory character as to the right of interference, which afterwards caused much embarrassment to these authorities when compelled to take more decisive action. By the acknowledgment of the independence of the native chiefs in 1831, and again in 1835, and by the appointment of Mr Busby as consul and British resident, but with no means at his disposal to maintain his authority, the British government endeavoured to meet the necessities of the case, and to throw obstacles in the way of colonization. Other views influenced a large class of merchants and gentry in Great Britain; and the New Zealand Company was formed in 1837, which, in the year 1839, received a charter, and immediately proceeded to send out colonists to New Zealand. This movement obliged the British government to establish its authority in the islands; and in order to this, Captain Hobson was sent out in August 1839 as consul. The missionaries and respectable Europeans at once rallied around a legitimate authority; and in February 1840 a large council was held at Waitangi, when all the chiefs of that part of the island agreed to acknowledge the Queen's supremacy—"giving up," as they said, "the shadow of the land, but retaining the substance." A second council was held at Hokianga, with similar results; and then Captain Hobson, as lieutenant-governor, proclaimed the British sovereignty over the Isles of New Zealand, 21st May 1840. The seat of government was at first established at Russell, in the Bay of Islands; but in 1841 was removed to Auckland, the present capital; and on the 3d May 1841 the colony was relieved from all dependence upon New South Wales. Meanwhile, a French expedition, sent to occupy Banks' Peninsula, in the middle island, was forestalled by Captain Stanley, who had pro-

Ney.

ceeded there a few days previously, and had planted the British flag. The New Zealand Company, which, by taking measures to colonize direct from England, had compelled the assumption of British sovereignty, planted its first settlements at Wellington, in Port Nicholson, and at Nelson in 1839; the year following, Wanganui and New Plymouth were established. The difficulty in obtaining possession and satisfactory title to land purchased by them from the natives, and dissensions with the new government of New Zealand, retarded the progress of these infant settlements, and involved many respectable colonists in ruin. Some untoward events were attendant upon this rapid influx of emigrants. In 1843 a fatal affray occurred at Wairau (in the middle island), in which a large party of European gentlemen were murdered in a dispute with certain natives respecting property in land. Two years after, the chief Heki raised the standard of rebellion in the northern island, and burned the town of Russell; and in 1846 there were disturbances in the Hutt River district. In 1847 there were petty disturbances in Wanganui, since the suppression of which there has been peace in New Zealand with the native tribes. The example of the New Zealand Company was followed by an association of gentlemen connected with the Church of England, who, in 1848, formed the Canterbury settlement; and the same year the Otago settlement was planted by gentlemen in connection with the Free Church of Scotland. No other colonies separate and distinct from these six have been established in the islands. The proceedings of the New Zealand Company provoked much animadversion and controversy both in England and in the colonies which they had originated; but to enter into the discussion of the merits of the case would require more space than can be afforded to this article, and, besides, would lead to no profitable result. The company was finally broken up in 1851, and its debt of L.200,000 has been thrown upon the land revenue of the New Zealand colony, much to the annoyance of the people of Auckland, whose province was beyond the sphere of the Company's operations. In order to reconcile the colony to this burden, a loan of L.500,000 has been guaranteed by the imperial government for the purpose of local improvements, &c. (W. B. B.)

NEY, MICHEL, a marshal and peer of France, was born at Sarrelouis on the 17th of January 1769. His father had been a soldier, but after the Seven Years' War had retired to his native village, where he exercised the humble trade of a cooper. Young Ney had received his education at a school kept by the monks of St. Augustin, under whom he appears to have made considerable progress in his studies; but being fired with military ardour by the recitals of his father, he early enlisted, in 1787, in a regiment of hussars, where he served for some time, and was a subaltern at the commencement of the Revolution. He then attained the rank of captain, in which capacity he made his first campaigns, acting as aide-de-camp to General de Lamarche, and afterwards as adjutant-general under the orders of Kléber. This latter employment afforded him several opportunities of distinguishing himself; and he was commonly known by the well-merited surname of "Indefatigable" bestowed on him by his admiring general. In the official reports of the time honourable mention is made of him at the passage of the Lhan in 1795, and also at the combats of Neuwied, Altenkirchen, Montabaur, and Würzburg. On the 8th of August 1796 he took Pfortzheim, and was promoted to the rank of brigadier-general. In the campaign of 1797 he was again successful; but his horse having been killed at the combat of Steimberg, he fell into the hands of the enemy. Hoche, who admired his undaunted courage, earnestly solicited his exchange, and, as soon as he had obtained it, appointed him general of division. It was in this capacity that, in 1798, Ney commanded the cavalry of the army which, under the orders of Schaumbourg, executed

Ney.

the invasion of Switzerland. On this occasion he acted towards the inhabitants with as much generosity as circumstances would permit; and the following year he acquired a great reputation under Massena, particularly at the battle of Zurich. In the year 1800 he served with the army of Moreau, and greatly distinguished himself both at Moeskirch and at Hohenlinden. After the peace of Luneville he returned to Paris, and was received with great distinction by Napoleon, who found him a wife in the person of Mademoiselle Augnié, a friend of Hortense Beauharnais. When Bonaparte wished to effect the entire subjugation of Switzerland, Ney was sent into that country with the title of minister plenipotentiary, and there seems to have won for himself the golden opinions of the people and the esteem of his master. In 1804 he obtained the baton of marshal of the empire; and the distinguished part which he played in the storming of Elchingen, on October 4, 1805, induced Napoleon, who was an eye-witness of his impetuous daring, afterwards to honour him with the rank and title of Duke of Elchingen. After the capitulation of Ulm, being ordered to occupy the Tyrol, he entered Innsbruck on the 7th of November, at the head of the sixth corps of the grand army, which he also commanded the following year in the contest with Prussia. Having contributed essentially to the victory of Jena, he appeared before Magdeburg, and, by a prodigy which still remains inexplicable, he, on the 11th of November 1806, in less than twenty-four hours, received the capitulation of that redoubtable fortress, made 23,000 prisoners, and took 800 pieces of cannon. In the beginning of 1807 he obtained a signal success before Thorn, where the whole Russian army had advanced to attack him, hoping to surprise him in his winter quarters; and, at a later period, he carried the town of Friedland at the battle of that name, which terminated the war in the north of Europe. But the war in which Napoleon found himself involved, if extinguished at one point, was assiduously kept alive at others. Scarcely had he concluded a peace with the Russians at Tilsit, when he hurried away to attack the Spaniards; and Marshal Ney, with his corps d'armée, was transported from the banks of the Niemen to those of the Ebro and the Tagus. The marshal, finding himself obliged to carry on a war of posts and of chicane in Galicia, lost a great number of men in this inglorious service, and with difficulty maintained his ground till the moment when he received orders to unite his corps with that of Massena, who had been sent in order to expel the English from Portugal. But this was found to be impracticable. It was judged that the lines of Torres Vedras could not be attacked with any prospect of success; and when Massena found himself constrained to retire before the Duke of Wellington, Ney commanded his rearguard, and in that difficult retreat displayed equal talent and courage. In 1812 he was recalled by Napoleon to assist in the approaching invasion of Russia, for which an army of more than four hundred thousand men had been assembled on the Vistula. At the terrible battle of Mojaïsk or Borodino Ney commanded the centre; and it was on this occasion, amid the carnage of a conflict unequalled in modern times, that "the bravest of the brave," as Ney was called by the army, earned the title of Prince of Moskwa. Nor did he display less valour and firmness in the disastrous retreat from Moscow, in which his corps almost entirely perished. Napoleon, in one of the bulletins of the army, designated him as having a soul tempered with steel. In 1813 Ney participated in the indecisive victories of Lützen and Bautzen; but he had the misfortune to lose the battle of Dennevitz, where he was defeated by Bernadotte and Bulow, with the loss of 13,000 men, 43 pieces of cannon, and 3 standards. This event made a deep impression upon his mind. Napoleon, according to St. Cyr, manifested no displeasure at the reverse, but ascribed it wholly to the peculiar difficulties of the military art. Ney returned,

Ney.

however, to Paris in a sort of disgrace. Nevertheless, he was again employed in the unfortunate winter campaign of 1814; and he was at Fontainebleau when Napoleon was compelled to abdicate. Ney contributed materially to bring about this event; and he was one of the first generals who submitted to the Bourbons. Having presented himself before Monsieur on the 12th of April, he said to that prince, "Your Royal Highness will see with what fidelity we can serve our legitimate king." He also went to pay his respects to the king at Compiègne, and was there most favourably received. Louis XVIII. himself received his oath as a chevalier of the order of Saint-Louis, confirmed to him all his titles and pensions, and created him a peer of France. Marshal Ney was living at his estate of the Coudreaux when Napoleon, having escaped from the island of Elba, landed on the coast of France in February 1815; and he there received orders from the minister of war to repair to his government of Besançon. He immediately proceeded to Paris, and presenting himself before the king, made great protestations of devotion, and, kissing the hand of Louis, declared to him that he would bring back the disturber of Europe in an iron cage. He then set out for the eastern frontier, assembled some regiments at Besançon, and placing himself at their head, proceeded towards Lyons. At Lons-le-Saulnier, however, he learned that Napoleon had already entered Lyons; and from this time great agitation manifested itself amongst the troops. Nevertheless, the marshal himself still appeared faithful to the king, and even exerted himself to calm the excitement which prevailed in the army; but in the night between the 13th and 14th of March, an emissary sent by General Bertrand brought him proclamations and letters from Napoleon. His old master knew well that the heroic marshal was much more at home in the field of battle than amid the mazes of political intrigue. Bonaparte accordingly made him brilliant promises, and styled him, as formerly, "the bravest of the brave." The marshal could not resist the seductions of the great general, and next day he read to the troops his famous proclamation, beginning with these words, "The cause of the Bourbons is for ever lost. It is the Emperor Napoleon, our sovereign, who is alone entitled to reign." His whole conduct during the Hundred Days was a consequence of this step. Napoleon sent him as extraordinary commissioner to survey the frontiers of the North, and also appointed him a member of his Chamber of Peers. In the short but decisive campaign which ensued he displayed all his accustomed gallantry. At Quatre-Bras, however, his usual success did not attend him. Five horses were shot under him at Waterloo; yet with a dauntless spirit, which no danger could quell, he headed the terrible charge of the guards on foot, his clothes pierced thick with balls. And when that fierce conflict was over, and his wild daring proved bootless, he was among the last to leave the bloody field. After the defeat of the French army he returned to the capital. When Paris capitulated, Ney, having no hopes of finding favour with the Bourbons, took refuge in Auvergne, where he was arrested in consequence of the ordinance of the 24th of July, in which he was described as one of the authors of the revolution of the 20th March. Being conducted to Paris, he was confined in the Conciergerie, subjected to several interrogatories, and at length brought before a court-martial, composed of marshals of France and lieutenant-generals, to whose competency he objected. His counsel insisted much upon this point, in which they were ultimately successful; the members of the court being glad to escape from an embarrassing position, by pronouncing their own incompetence to try the prisoner. By an ordinance of the king, Ney was then brought before the court of the peers, whose competency was not disputed. But his counsel remonstrated warmly against the expressions employed by the ministers, who had declared that

it was "in the name of Europe" that they demanded his trial; and the same learned persons appealed with much force and eloquence to the conditions of the capitulation of Paris, which guaranteed to all who were within the walls of the capital that they should neither be disturbed nor sought after on account of their political conduct. All their efforts to save their client were, however, unavailing. After fifteen sittings, Marshal Ney was condemned to death, on the 6th of December 1815, by a large majority; and the following day the sentence was carried into execution. "He who," says Napier (*Peninsular War*, vol. ii.), "had fought 500 battles for France—not one against her—was shot as a traitor" by a platoon of veterans, near the palace of the Luxembourg, where he had been condemned; and displayed in his last moments the same heroic courage which had so often distinguished him in the field of battle. His body was given to his friends, and conveyed to the cemetery of Père la Chaise, where his tomb may now be seen. Marshal Ney and Colonel Labédoyère were the only victims of a revolution where it is evident that neither played the principal part, and that both were led away by the force of circumstances, and the spell which Napoleon exercised over the minds of the officers as well as the common soldiers of the army. (J. B.—E.)

NEYVA, or NEIVA, a town of New Granada, on the Magdalena, at its confluence with the River Neyva, 130 miles S.W. of Bogota. It is a place of considerable trade, chiefly in cacao of excellent quality. It suffered much from an earthquake in 1827, but is still a place of some importance.

NGAMI, a lake of Southern Africa, lying between S. Lat. 20. 23. and 20. 40.; E. Long. 22. 30. and 24. Reports of the existence of this lake had been received a long time before it was actually reached by European travellers; it occurs on Portuguese maps as early as 1508; and its position was laid down with considerable accuracy nearly twenty years before it was visited by Livingston, Murray, and Oswell, July 28, 1849. They approached it from the south, having crossed the Kalahari Desert, which had for a long time presented an insuperable obstacle to any attempts to explore the country in this direction. Four years afterwards the lake was again reached by Mr Anderson, who, following a course which had been formerly deemed impracticable, started from Walvisch Bay, on the W. coast of Africa, arrived at the western end of the Ngami, and then travelled round a great part of its banks. The discovery is of very great interest and importance, not only because it enlarges our knowledge of the geography and natural history of the interior of Africa, but also as it may tend to open up those hitherto inaccessible regions to the influences of commerce, civilization, and religion. The lake is known by the natives under various names, derived from its different characteristics, such as *Inghate*, or the "Giraffe;" *Noka ea Mokorön*, or the "Lake of Boats," &c.; but that which has been adopted by Europeans is *Ngami*, which signifies "The Waters." Its size was at first somewhat over-estimated, on account of the low and almost undistinguishable character of part of its banks, and in consequence of the original discoverers having mistaken its length for its breadth. It extends from E. to W., having a length of about 40 miles, a breadth at the widest part of 10, and an average breadth of 8 miles. Its circumference is about 70 or 80 miles, and its area about 295 square miles. Its shape is somewhat like that of a pair of spectacles, being narrow in the middle and spreading out at each end to a considerable width. Its northern bank is lined by a low and sandy tract of country, entirely destitute of vegetation. This region has a breadth of about a mile, beyond which distance the country is thickly wooded with various kinds of acacia and other trees, among which the enormous baobab is here and there seen raising its head

Neyva
||
Ngami.

Ngami. above the forest. The southern and western shores are considerably higher; and the water is bordered by strips of ground so thickly covered with reeds and rushes as to admit of access to the lake only at a few points. The water is very shallow at the western end of the lake; but the depth is more considerable towards the eastern extremity. A remarkable peculiarity of the waters of the Ngami is, that they are subject to a regular ebb and flow every twenty-four hours. The ebb takes place during the night, when the wind that prevails during the day entirely falls, but in the morning the waters return to their original position. This curious phenomenon has been supposed to depend on the wind. Lake Ngami is fed by the Teoge, which enters it from the N.W., and discharges into it a considerable volume of water during the time of its annual rise, which occurs in June, July, and August, and sometimes later. This river has not as yet been explored to any great distance; but it is believed to be of great length, rising probably near the sources of the Coanza and other large rivers. Its course is very circuitous, and it is said to be wider further up than it is near the lake. During the time of flood its depth is considerable; and it has been navigated with canoes for about 65 miles from the lake. An outlet to the waters of the lake is furnished at its eastern extremity by the broad and gently-flowing river Zouga, which pursues an easterly course for about 300 miles, and is then lost in an immense sandy marsh, though it has been supposed by some that it pursues its course underground, and finally discharges itself into the Indian Ocean. A branch of the Teoge is said to join this river, and at some seasons of the year to force back its waters to the lake. The scenery along the Zouga is extremely beautiful, and the thick and luxuriant forests in many places extend to the very edge of the water. To the west of the Teoge two other rivers are reported to exist, one of which is small, and loses itself in the sand; while the other flows parallel to the Teoge, but in an opposite direction, and joins the Cunene, a river which falls into the Atlantic. By this latter river it is probable navigation might be established from the sea-coast to the fertile land in the interior. A great number of wild animals are found in the neighbourhood of the lake, of which the elephant, rhinoceros, buffalo, giraffe, and antelope, are the principal. Hippopotami are numerous, especially at the north-western extremity of the lake; and the rivers and lake abound in otters and crocodiles. The birds of this region are also many and various, including many species of ducks and geese, herons, storks, cranes, &c. The inhabitants of the lake country are called *Batoana*, and form a small tribe of the large and powerful family of the Bechuanas, who are widely spread throughout Southern Africa. This tribe, however, is not aboriginal in this district, but has only recently settled here, having conquered and reduced to slavery the original inhabitants, who called themselves *Bayeye*, or "men," but are styled by the Batoana, *Bakoba*, or "serfs," in consequence of their condition. The appearance of the Batoana is handsome; but the women are generally short and stout, and they encumber themselves with numerous strings of beads, and with iron, brass, and copper rings on their arms and legs. They smear their bodies with grease and red ochre, which they conceive to be a much superior practice to washing themselves. They are extremely fond of snuff, and indulge much, especially the women, in the habit of smoking. The principal occupations of the men are, war, hunting, and the making of skins and furs into garments; while to the women are left the more arduous tasks of building the house, cultivating the ground, preparing the corn, and rearing the family. They are not deficient in intelligence, but this for the most part takes the form of deceitfulness and cunning; and though outwardly they are frank and well-behaved, this arises rather from their

habits of politeness and etiquette than from real kindness of disposition. They are much given to revenge, but easily appeased by presents. The prevailing vice among this people is theft, and even their chiefs are not safe from their pilfering propensities. They have no religion, nor any notions of a Supreme Being; but they believe implicitly in wizards, and especially in the "rain-makers," although they frequently put them to death when disappointed in their expectations. The government is monarchical and patriarchal, each tribe being governed by a chief, who resides in the principal town, and has under him several inferior chiefs at the head of the smaller towns and villages. These inferior chieftains maintain a check on the power of the king, which is in other respects despotic. They assemble in meeting called *pichos*, where speeches are often heard of considerable ability and even eloquence. The principal town of the Batoana tribe is situated at the east end of the lake, on the north bank of the Zouga. The principal articles of commerce that have yet been found in the lake district are hides and furs of different sorts, ostrich feathers, rhinoceros' horns, and ivory; while the natives demand in exchange beads and ammunition, but especially the latter. (See *Lake Ngami; or, Explorations and Discoveries during Four Years' Wandering in the Wilds of South-Western Africa*, by Charles John Anderson, London, 1856; and Livingston's *Travels and Memoirs*.)

NGANHOEI, an inland province of China, bounded on the N.E. by Kiangsoo, S.E. by Chekiang, S. by Kiangsee, W. and N.W. by Houpe and Honan. It lies between N. Lat. 29. 5. and 34. 18., and E. Long. 114. 50. and 119. 17.; and has an area of 48,461 square miles. The surface for the most part is level; but towards the south and west ranges of hills occur, never, however, rising to any great height. The principal rivers are the Yang-tse-Kiang and the Hoai-ho, with their affluents. There are several lakes, of which the Chau-hu, or Nest Lake, is the largest. Mines of gold, silver, copper, &c., are worked; and the soil is very productive, especially of green tea, in the south-eastern regions, which are the best in China for the growth of this plant. Ink and lanterns are the principal manufactures of the province. Pop. 34,168,059.

NIAGARA. See CANADA.

NICÆA (*Ishnik* or *Isnik*), a well-built and important city of Bithynia, stood in a spacious and fertile plain on the eastern shore of the Lake of Ascania (*Lake of Isnik*). According to one tradition, it was built by some of Alexander's soldiers, natives of Nicæa in Locris, and derived its name from the birth-place of its founders. Another account, however, states that it was erected on the ruins of a former town (Ancore or Helicore), by Antigonus, and was called after him *Antigoneia*, and that this name was afterwards changed into Nicæa, in honour of Nicæa, the wife of Lysimachus. The town enjoyed a long career of prosperity under the different governments that successively ruled over it. Under the native kings of Bithynia it was important enough to compete with Nicomedia for the honour of being considered capital of the country. During its subjection to the Romans many of its public buildings were restored, and its streets were often the scene of the celebration of great festivals in honour of the emperors and the gods. In the time of the Eastern Empire the city was enlarged, was surrounded with new walls, and became famous throughout Christendom as the place where, in 325 A.D., the Nicene creed was drawn up. (See *NICE, Council of*.) After being during the middle ages a frequent subject of dispute between the Turks and the Christians, it was constituted by Theodore Lascaris, in the thirteenth century, the capital of Western Asia. At length, however, in the fourteenth century, on being incorporated with the Ottoman empire by the Emir Orchan, Nicæa began to decline in prosperity.

Nicæa
||
Nicaragua.

Many of the fine Greek temples and churches were then pulled down to furnish materials for mosques and other buildings. From that time the large city gradually dwindled down until, in the present day, it has become a poor paltry village of little more than a hundred houses. Yet many ruined baths and edifices standing amid gardens and corn-fields, and a large portion of the ancient walls, still indicate to the visitor the splendour and magnitude of the ancient Nicæa.

NICÆA, a town of Liguria. See NICE.

NICANDER, the author of two Greek poems on poisons and antidotes, was a native of Claros near Colophon in Ionia, and flourished in the second century B.C., in the reign of Attalus, the last king of Pergamus. He succeeded his father Damnæus in the hereditary office of priest of Apollo Clarius. His poems show that he possessed a fine talent for observation, and was fully equal to the other naturalists of his own age. The other features, however, of his literary character are not so favourable. His dissertations were unmethodical and often prolix; he was ever on the outlook for obsolete and antiquated expressions, which must often have rendered his meaning obscure even to his contemporaries; and almost the only quality of the poet he evinced was a fondness for the strange and the fabulous. The longer of his two extant poems is entitled *Theriaca*, treats of the wounds inflicted by poisonous animals, and consists of nearly a thousand hexameter verses. Among the curious zoological passages which are found heterogeneously mingled with erroneous doctrines and absurd fables, are the first account ever given of the moths that flutter round the evening candle, and an interesting description of the resistance that the serpents make in defence of their eggs against the ichneumon. The other poem, entitled *Alexipharmaca*, is a treatise, as its name implies, on antidotes, and contains more than 600 hexameter lines. It seems to have been intended for a continuation of the *Theriaca*, and accordingly it gives an account of the effect of different poisons. A full analysis of the medical portions of these two poems is given in Dr Adams' edition of the work of Paulus Ægineta. Nicander was the author of several other productions, both prose and poetical, of which little more than the titles remain. The best edition of his works, entire and fragmentary, is that of J. G. Schneider, in two volumes, published respectively at Halle in 1792, and at Leipsic in 1816.

NICARAGUA, an independent republic, formerly one of the states of the Republic of Central America, and, under the Spanish dominion, one of the provinces of the captain-generalcy, called also the kingdom, of Guatemala. The boundaries claimed by the republic of Nicaragua are those which pertained to it as a province, viz.,—the Caribbean Sea on the E., from the lower or Colorado mouth of the San Juan River to Cape Gracias á Dios; and the Pacific Ocean on the W., from the mouth of the Rio Salto de Nicoya or Alvarado on the Bay of Nicoya to the Bay of Fonseca. On the N., and separating it from Honduras, its boundary extends from the mouth of the Rio Negro, falling into the Bay of Fonseca, to the head-waters of the Rio Wanks or Segovia, following down that river to the sea at Cape Gracias. Its southern boundary, separating it from Costa Rica, is claimed to be a right line drawn from the Colorado mouth of the San Juan river to the mouth of the Rio Salto de Nicoya. Nicaragua is, therefore, embraced between 83. 20. and 87. 30. W. Long., and 9. 45. and 15. N. Lat., and, according to these claims, embraces an area of not far from 59,000 square miles.

A considerable part of this territory, however, embracing the entire Atlantic coast, with an undefined extent inland, from the River San Juan to Cape Gracias, has been claimed on behalf of the Mosquito Indians (see MOSQUITO SHORE); but the claim has never been conceded by Nicaragua. The

whole territory south of the River San Juan, and below the little River Flores, flowing into the Pacific, embracing the ancient department of Guanacaste, has been claimed by Costa Rica, and is at present in the actual occupation of that state. Should these claims be ultimately admitted, they will reduce by nearly one half the territorial area of the republic.

The geographical and topographical features of Nicaragua are not only remarkable, but interesting to the world at large, from the facilities which they are supposed to afford for opening a ship-canal between the Atlantic and Pacific Oceans. The northern part of the republic, embracing the whole of the district of Segovia, and a portion of Chontales, borders on the high grounds or plateau of Honduras, and partakes of its mountainous character. The valleys are narrow, and the numerous streams which flow through them rapid and turbulent. The hills are clothed with pines and oaks, and the aspect and climate of the region are those of the temperate zone. Here are found numerous rich mines of gold, silver, and copper; and many of the streams carry gold in their sands, whence it is washed in considerable quantities by the Indians. To the southward of this elevated district, and between it and the high mountain group or centre of elevation in Costa Rica, is the great basin of the Nicaraguan lakes, lying transversely to the great range of the Cordilleras, and completely interrupting it. It is precisely this physical feature which has directed attention to Nicaragua, as probably the best point where the oceans may be connected by a canal. This great basin or valley is not far from 300 miles long by 150 miles wide, and consists in great part of broad, beautiful, and fertile plains. In its centre are spread out the Lakes of Nicaragua and Managua, which collect the waters flowing inward from every direction, and discharge them through a single outlet, the Rio San Juan, into the Caribbean Sea. Some of the streams flowing into these lakes, especially those from the north, are of considerable size, and furnish a supply of water which could not be sensibly affected by drains for artificial purposes. Lake Managua is a beautiful sheet of water, nearly 50 miles long by 25 broad, and with an average depth of 5 fathoms of water. It approaches, at the nearest point, to within 20 miles of the Pacific Ocean, from which it is separated on the south by a range of low volcanic hills; but between its northern extremity and the sea there are only the magnificent plains of Leon and El Conejo, in the midst of which rise the regular cones of the volcanoes of El Viejo, Telica, and Axusco. The gigantic volcano of Momotombo stands out boldly into the lake; its bare and blackened summit, which no human foot has ever pressed, crowned with a light wreath of smoke, attesting the continued existence of those internal fires which have seamed its steep sides with burning floods, and which still send forth hot and sulphurous springs at its base. Upon the northern and eastern shores of the lake, lifting their blue, rugged peaks one above another, are the mountains of Matagalpa, gradually merging into those of Segovia, rich in metallic veins. Upon the south and west are fertile slopes and broad plains, covered with luxuriant verdure, and of almost unlimited productiveness; while in the lake itself stands the Island of Momotombita, an almost perfect cone in outline, covered with a dense forest, in the deepest recesses of which are still found gigantic idols, the rude relics of aboriginal superstition. The town of Leon was first built on the north-western shore of the lake, at a place now called Moabita, which was subsequently abandoned for its present site, in the midst of the great plain of the Marabios. From this circumstance the lake is sometimes called Lake Leon. The great feature of Nicaragua, however, is the lake of the same name, the Cocibolca of the aborigines, which is unquestionably one of the finest bodies of water on the American continent. It is upwards of 100 miles in greatest length, by about

Nicaragua.

Nicaragua. 40 miles in average width. Upon its southern shore, near the head of the lake, stood the ancient city of Granada, lately the rival of Leon, and once the most important commercial town in the republic. A few miles below Granada, and projecting boldly into the lake, is the extinct volcano of Mombacho, 5000 feet in height. Studding the lake at its base, is a cluster of innumerable small islands called *Los Corales*, of volcanic origin, rising in the form of cones to the height of from 20 to 100 feet, and covered with verdure. Upon the same shore with Granada, but 40 miles distant, is the ancient city of Rivas or Nicaragua, the capital of a large, fertile, and comparatively well cultivated district. Flowing into the lake, at its extreme southern extremity, nearly at the same point where the Rio San Juan (the ancient *El Desaguadero*) commences its course, is the considerable Rio Frio, which has its origin at the base of the great volcano of Cartago in Costa Rica. It flows through an unexplored region, inhabited by an unconquered and savage tribe of Indians called Guatusos, of whose ferocity the most extraordinary stories are related. The northern shore of the lake, called Chontales, for the most part is undulating, abounding in broad savannas, well adapted for grazing, and supporting large herds of cattle. There are a number of considerable islands in the lake, the largest of which are El Tapatero, Solentenami, and Omotepec. The two former are deserted, but the latter has a considerable population of Indians of the pure Mexican or Aztec stock. This island is distinguished by two high conical mountains or volcanic peaks, called respectively Omotepec and Madeira, which are visible from every part of the lake, and from a distance of many leagues on the Pacific. The name of the island, in the Nahuatl or Mexican language, signifies "two mountains," from *ome*, two, and *tepec*, mountain. The water of the lake, in most places, shoals very gradually; and it is only at a few points that vessels of considerable size may approach the shore. Still, its general depth, for all purposes of navigation, is ample, except near its outlet, where for some miles it does not exceed from 5 to 10 feet. There are points, however, where the depth of water is not less than 40 fathoms. The prevailing winds on the lake, as indeed of the whole state, are from the N.E.; they are, in fact, the Atlantic trades, which here sweep entirely across the continent, and encountering the conflicting currents of air on the Pacific, form those baffling revolving winds, detested by navigators, under the name of *Papagayos*. When the winds are strong the waves of the lake become high, and roll in with all the majesty of the ocean. At such times the water of the lake is piled up, as it were, on the southern shore of the lake, occasionally producing overflows of the low grounds. As the trade winds are intermittent, blowing freshly in the evening, and subsiding towards morning, the waters of the lake seem to rise and fall accordingly; and this circumstance gave rise to the notion, entertained and promulgated by the ancient chroniclers, that the lake had a regular tide like that of the sea. Some of them imagined, in consequence, that it communicated with the ocean by a subterranean channel. As already observed, the sole outlet of the great Nicaraguan basin, and of the lakes just described, is the River San Juan, debouching into the Caribbean Sea, at the now well-known port of San Juan (Greytown). This river is a magnificent stream, but its capacities have been greatly exaggerated, as will be seen in the paragraphs referring to the proposed ship-canal. It flows from the south-eastern extremity of Lake Nicaragua, nearly due east to the ocean. With its windings it is 119 miles long. The body of water which passes through it varies greatly at different seasons of the year. It is, of course, greatest during what is called the "rainy season;" that is to say, from May to October. To this variation, in some degree, may be ascribed the wide difference in the statements of the

depth and capacity of the river made by different observers. Nicaragua. Several considerable streams enter the San Juan, the largest of which are the San Carlos and Serapiqui, both rising in the highlands of Costa Rica. The streams flowing in from the north are comparatively small; indicating that the mountains are not far distant in that direction, and that upon that side the valley is narrow. The Serapiqui is ascended by canoes to a point about 20 miles above its mouth, where commences the road, or rather mule-path, to San José, the capital of Costa Rica. About midway between the lake and the ocean, on the south bank of the river, are the ruins of the old fort or castle of San Juan, captured by the English in 1780. The expedition against it was commanded by Colonel Polson, with captain, afterward Lord Nelson, as second in command. Of 200 men under Nelson, drawn from his vessel, the *Hinchenbrook*, but ten returned to the coast. At one time, besides this fort, another at the head of the river (San Carlos), and a third at its mouth, the Spaniards kept up not less than twelve military stations on its banks. The width of the river varies from 100 to 400 yards, and its depth from 2 to 20 feet. It is interrupted by five rapids,—viz., Rapides del Toro, del Castillo, de los Valos, del Mico, and Machuca. The Machuca rapids are the largest, and in many respects the worst in the river. For a distance of nearly half a mile the stream is spread over a wide and crooked bed, full of large rocks projecting above the surface, between which the water rushes with the greatest violence. They are considered dangerous by the native boatmen, who are only enabled to ascend them by keeping close to the northern shore, where the current is weakest, and the bed of the river least obstructed. Here the *bougos* or boats are pushed up by main force. The late Transit Company lost a number of their small steamers on these rapids, which, without great artificial improvement, must remain an insuperable obstacle to regular steam navigation on the river. The rapids of El Castillo are short, and deserve rather the name of falls. Here the water pours over an abrupt ledge of rocks, falling 8 feet in but little more than the same number of yards. Bougos are unloaded here, and the empty boats trucked past by men stationed there for the purpose. The steamers of the Transit Company did not attempt to pass these rapids, the passengers and merchandise being transferred by means of a tram-road to vessels above. The remaining rapids, although formidable obstacles to navigation, do not require a special description. The banks of the San Juan, for 20 miles from the lake, and for about the same distance above its mouth, are low and swampy, lined with palms, canes, and a variety of long coarse grass called *gamalote*. Elsewhere the banks are generally firm, in some places rocky, from 6 to 20 feet high, and above the reach of overflows. They are everywhere covered with a thick forest of large trees, draped all over with *lianes* or woodbines, which, with the thousand varieties of tropical plants, form dense walls of verdure on both shores of the stream. The soil of the river-valley seems uniformly fertile, and capable of producing abundantly all tropical staples. Like the Atrato, the San Juan river has formed a delta at its mouth, through which it flows for 18 miles, reaching the sea through several channels. The largest of these is the Colorado Channel, which opens directly into the ocean; the next in size is that which bears the name of the river, and flows into the harbour of San Juan. Between the two is a smaller one called Tauro. This delta is a maze of low grounds, swamps, creeks, and lagoons, the haunts of the manati and alligator, and the homes of innumerable varieties of water-fowl. The port of San Juan (Greytown) derives its principal importance from the fact that it is the only possible eastern terminus for the proposed inter-oceanic canal, by way of the River San Juan and the Nicaraguan lakes. It is small, but well protected,

Nicaragua. easy of entrance and exit, and has a depth of water varying from 3 to 5 fathoms. Upon the Pacific the best port of the republic is that of Realejo, anciently Posession, which is capacious and secure, but difficult of entrance. The little bay of San Juan del Sur, which was used as the Pacific port of the late Transit Company, is small and insecure, and scarcely deserves the name of harbour. The same may be said of the so-called ports of Brito and Tamaranda. A good port is said to exist on Salinas Bay; but this falls on that part of the coast in dispute with Costa Rica.

Next to its great lakes, the most striking physical features of Nicaragua are its volcanoes, which bristle along its Pacific coast, in nearly a right line, from the Bay of Fonseca to that of Nicoya. Commencing at the volcano of Cosequina, we come in order to El Viejo, Santa Clara, Telica, Las Pilas, Orotá, Axusco, Momotombo, Masaya or Nindirí, Mombacho, Ometepe, Madeira, Solentanami, and Orosi, of which Cosequina, Momotombo, Masaya, and Orosi are said to be *vivo*, or active. Besides these volcanic peaks, there are numerous ancient craters and fissures giving forth smoke and sulphurous vapours, called *Infernillos*. At the time of the conquest of Nicaragua, in 1520, the volcano of Masaya, then called the "Hell of Masaya," was in active eruption. Oriedo, the chronicler of the Indians, has left us a graphic account of it as it then appeared. It has had one or two violent eruptions since that period, and after more than half a century of quiescence, is now (1857) throwing out volumes of smoke, and giving other evidences of renewed activity. It is a low, broken mountain, and the country for miles around its base is covered with lava. The volcanoes on the plain of Leon, known as Los Marabios, were also active at the period of the conquest; and as late as Dampier's time, El Viejo was "a volcano or burning mountain." Momotombo to this day sends out a constant column of smoke, and an occasional cloud of ashes. The eruption of the volcano of Cosequina in 1835 was one of the most fearful on record. It commenced on the 30th of January of that year, and continued with uninterrupted violence for four days, and then suddenly ceased. For three days the clouds of smoke and sand which it sent forth totally obscured the sun for the distance of a 100 miles. Sand fell in Jamaica, in Santa Fe de Bogota, and in Mexico, over an area of more than 1500 miles in diameter. The explosions were heard 800 miles; and a ship off the coast sailed for 50 leagues through floating masses of pumice, which almost entirely concealed the surface of the water. Since 1835 this volcano has remained perfectly quiet, with no signs of activity, except a few rills of smoke and vapour, indistinguishable at a distance. The volcano of Orosi is in a state of constant activity. Besides the volcanoes themselves, and the hundred yawning craters amongst the hills, there are numerous lakes of volcanic origin, shut in by vitrified, blistered, and precipitous walls of rock, without outlets, and often of great depth. Such is the remarkable Lake of Masaya, near the volcano of the same name, which furnishes water, not only to the considerable town of Masaya, but also to the inhabitants of numerous villages in its vicinity. It is about 10 miles in circumference, and its surface 500 feet below the general level of the country. The water is reached by steep, narrow paths, half cut in the rock, and is carried up by the *aguadoras* in jars, supported on their heads, or on their backs, by bands passing around their foreheads. In some of these volcanic lakes the water is fresh and good; in others salt and bitter. Perhaps no equal extent of the earth's surface exhibits so many or so marked traces of volcanic action as that part of Nicaragua intervening between its lakes and the Pacific Ocean.

The climate of Nicaragua, except among the mountains of Chontales and Segovia, is essentially tropical, but nevertheless considerably modified by a variety of circumstances.

The absence of high mountains towards the Atlantic, and the broad expanse of its lakes, permits the trade-winds here to sweep entirely across the continent, and to give to the country a degree of ventilation agreeable to the senses, and favourable to health. The region towards the Atlantic is unquestionably warmer, more humid, and less salubrious, than that of the interior, and of the country bordering on the Pacific. The Nicaragua basin proper, and within which the bulk of its population is concentrated, has two distinctly marked seasons, the wet and the dry; the first of which is called summer, the latter winter. The wet season commences in May, and lasts until November; during which time, but usually near the commencement and the close, rains of some days' duration are of occasional occurrence, and showers are common. The latter do not often happen except late in the afternoon, or during the night. They are seldom of long continuance, and often days and weeks elapse, during what is called the rainy season, without a cloud obscuring the sky. Throughout this season, the verdure and the crops, which, during the dry season, become sere and withered, appear in full luxuriance; the temperature is very equable, differing a little according to locality, but pursuing a very nearly uniform range from 78° to 88° of Fahrenheit; occasionally sinking to 70° in the night, and rising to 90° in the afternoon. During the dry season, from November to May, the temperature is less, the nights positively cool, and the winds occasionally chilling. The sky is cloudless; and trifling showers fall at rare intervals. The fields become parched and dry, and the cattle are driven to the borders of the streams for pasturage; while in the towns the dust becomes almost insufferable. It penetrates everywhere, sifting through the crevices of the tiled roofs in showers, and sweeping in clouds through the unglazed windows. This season is esteemed the healthiest of the year. Its effect is practically that of a northern winter, checking or destroying that rank and ephemeral vegetation which, constantly renewed where the rains are constant, as at Panama, form dense, dark jungles, the birth-places and homes of malaria and death. For the year commencing September 1850, and ending September 1851, the thermometer at the town of Rivas gave the following results:—Mean highest, 86°·45 of Fahr.; mean lowest, 71°·15: mean average for the year, 77°·42; mean range, 15°·3. The amount of rain which fell from May to November inclusive was 90·3 inches; from December to April inclusive, 7·41 inches. None fell in February; but 22·64 inches fell in July, and 17·86 inches in October.

The natural resources of Nicaragua are very great. The staples of the tropics, cotton, sugar, indigo, tobacco, rice, cacao, coffee, &c., may be produced in the greatest abundance. The cotton, although as yet, from lack of sufficient labour, produced in but small quantities, is of a superior quality. The cacao of Nicaragua has long been celebrated as next only to that of Soconusco in quality and value. Its sugar is produced from a plant slenderer, but containing more and stronger juice, than the variety cultivated in the West India Islands. Two crops, and sometimes, when the fields are irrigated, three crops are taken from the same ground annually. This cane seldom requires to be replanted oftener than once in twelve or fourteen years. The crystals of the sugar are remarkably large and fine; and the sugar itself, when carefully manufactured, nearly equal in beauty to the refined sugar of commerce. The indigo is produced from an indigenous plant called *juiquilite* (*Indigofera disperma*, Lin.), and has a high reputation in commerce. Coffee flourishes well on the higher grounds, but is not extensively cultivated. The same may be said of tobacco, which is a government monopoly, and its production not allowed, except in certain quantities. Maize grows in great perfection, and, manu-

Nicaragua. factured into *tortillos*, constitutes a principal article of food. Cattle are numerous, and hides form a large item amongst the exports of the country. Dye-woods, chiefly the *braziletto*, are also extensively exported. In short, nearly all the edibles and fruits of the tropics are produced naturally, or may be cultivated in great perfection; plantains, bananas, beans, tomatoes, yams, arrow-root, citrons, melons of all kinds, limes, lemons, oranges, pine-apples, guavas, cocoa-nuts, and many other varieties of fruits and vegetables. Among the vegetable productions which enter into commerce, may be mentioned sarsaparilla, arnotta, vanilla, ginger, gum-copal, gum-arabic, copaiba, caoutchouc, dragon's-blood, &c. The mineral resources of Nicaragua are also very great. Gold, silver, copper, lead, and iron are found in considerable quantities in various parts, but chiefly in the districts of Segovia and Chontales. The production of these metals has greatly fallen off since the assertion of the country's independence; still the produce is considerable; but such is the unsettled state of the country, it is impossible to obtain any satisfactory statistics concerning it. Sulphur may be had in inexhaustible quantities, crude and nearly pure, from the volcanoes; nitre is also abundant, as also sulphate of iron. Notwithstanding the variety of its products, and the ease with which they may be prepared for market, the commerce of Nicaragua is very small. The wants of its people are few and easily supplied.

Politically, Nicaragua is divided into five departments, exclusive of the disputed department of Guanacaste, each of which is subdivided into districts for municipal and other purposes. The departments are as follows:—

Departments.	Capitals.	Population.
Meridional.....	Rivas.....	20,000
Oriental.....	Granada.....	95,000
Occidental.....	Leon.....	90,000
Septentrional of Matagalpa.....	Matagalpa.....	40,000
Septentrional of Segovia.....	Segovia.....	12,000
Total.....		257,000

The population here given is the result of a census attempted in 1846. Making due allowance for deficiencies, we may estimate the actual population of Nicaragua at not less than 300,000; and it may be divided as follows, with approximate exactness:—

Whites.....	30,000
Negroes.....	18,000
Indians.....	96,000
Meztizos.....	156,000
Total.....	300,000

The people generally live in towns, many of them going 2, 4, and even 6 miles, to labour in their fields, starting before dawn, and returning in the evening. The plantations, *haciendas*, *hattos*, *huertas*, &c., are scattered over the country, and are often reached by paths so obscure as almost wholly to escape the notice of the travellers. The dwellings are usually of canes, thatched with palm, many of them open at the sides, with no other floor than the bare earth, and deserving of no better name than that of huts. These fragile structures, so equable and mild is the climate, are adequate to such protection as the natives are accustomed to consider necessary. Some of the dwellings are more pretending, are roofed with tiles, and have the canes plastered over and white-washed; and there are a few, belonging to large proprietors, which are roomy, neat, and comfortable. In the towns, the residences of the better classes are built of *adobes* or sun-dried bricks, inclosing large courts, faced by broad corridors. The churches, as usual in Catholic countries, monopolize nearly all that there is of architectural skill and beauty. Their leading features are

Moresque; but there are a few, and conspicuously among them the great cathedral of Leon, which are of simpler and more classical styles. This cathedral is of substantial masonry throughout. It was finished in 1743, after having occupied thirty-seven years in building. The cost is said to have been L.1,000,000 sterling. Nothing can better illustrate its strength than the fact, that it has endured unimpaired the earthquakes and storms of more than a century. During the frequent revolutionary paroxysms of the country, it is used as a fortress, heavy guns being mounted on the roof. It has sustained several severe cannonades.

The project of opening a canal for ships through Nicaragua began to be entertained as soon as it was found that no natural communication existed between the oceans, as early as 1527. Since that period it has furnished a subject for much speculation; but beyond a few partial examinations, until very lately, nothing of a practical or satisfactory character had been attempted. In 1851 a careful survey was made of the River San Juan, Lake Nicaragua, and the isthmus intervening between this lake and the Pacific, by Colonel Childs, under the direction of the now extinct "Atlantic and Pacific Ship Canal Company." Until then, it had always been assumed that the River San Juan, as well as the lake itself, could easily be made navigable for ships, and that the only obstacle to be overcome was the narrow strip of land between the lake and the ocean. Hence, all the so-called surveys were confined to that point alone. One of these was made, under the orders of the Spanish government, by Don Manuel Galisteo, in 1781. Another, and that best known, by Mr John Bailly, under the direction of the government of Central America in 1838. An intermediate examination, quoted by Thompson, seems to have been made early in the present century. The following table will show the results of these surveys as regards this particular section:—

Authorities.	Distance from Lake to Ocean.	Greatest Elevation above Ocean.	Greatest Elevation above Lake.
	Miles feet.	Feet.	Feet.
Galisteo, 1781.....	17 200	272	134
Quoted by Thompson, 18—...	17 330	296	154
Bailly, 1838.....	16 730	615	487
Childs, 1851.....	18 588	159	47½

As the survey of Colonel Childs is the only one which can be accepted as conforming to modern engineering requirements, it will be enough to present the detailed results at which he arrived. The line proposed by him, and on which all his calculations and estimates were based, commences at the little port of Brito on the Pacific, and passes across the isthmus between the ocean and the lake, to the mouth of a small stream called Rio Lajas, flowing into the latter; thence across Lake Nicaragua to its outlet, and down the valley of the Rio San Juan to the port of the same name, on the Atlantic. The length of this line was found to be 194½ miles as follows:—

	Miles.
<i>Western Division</i> :—Canal from the port of Brito on the Pacific, through the valleys of the Rio Grande and Rio Lajas, flowing into Lake Nicaragua.....	18-588
<i>Middle Division</i> :—Through Lake Nicaragua, from the mouth of Rio Lajas to San Carlos at the head of the San Juan River.....	56-500
<i>Eastern Division</i> :— <i>First Section</i> :—Slack water navigation on San Juan River, from San Carlos to a point on the river nearly opposite the mouth of the Rio Serrapiqui.....	90-800
<i>Second Section</i> :—Canal from point last named to port of San Juan del Norte	28-505
Total as above.....	194-393

The dimensions of the canal were designed to be—Depth 17 feet; excavations in earth, 50 feet wide at bottom, 86 feet wide at 9 feet above bottom, and 118 feet wide at surface of water; excavations in rock 50 feet wide at bottom, 77 feet wide at 9 feet above bottom, and 78½ feet wide at surface of water.

The construction of the canal on this plan contemplates supplying the western division, from the lake to the sea, with water from the lake. It would, therefore, be necessary to commence the work on the lake at a point where the water is 17 feet deep at mean level. This point is opposite the mouth of the little Rio Lajas, and twenty-five chains from the shore. From this point, for 1½ mile, partly along the Rio Lajas, the excavation will be principally in earth; but beyond this, for a distance of 5½ miles, which carries

Nicaragua. the line beyond the summit, three-fourths of the excavations would be in trap rock, that is to say, the deepest excavation or open cut would be $64\frac{1}{2}$ feet (summit $47\frac{1}{2}$ feet + depth of canal 17 feet = $64\frac{1}{2}$ feet), and involve the removal of 1,870,000 cubic yards of earth, and 3,378,000 cubic yards of rock. The excavation and construction on this $5\frac{1}{2}$ miles alone was estimated to cost upwards of L.1,250,000. After passing the summit, and reaching the valley of a little stream called Rio Grande, the excavation, as a general rule, would be only the depth of the canal. Mr Childs found that the lake at ordinary high-water is 102 feet 10 inches above the Pacific at high, and 111 feet 5 inches at low tide, instead of 128 feet, as calculated by Mr Baily. He proposed to accomplish the descent to Brito by means of fourteen locks, each of 8 feet lift. The harbour of Brito, as it is called, on the point where the Rio Grande enters the sea, is in fact only a small angular indentation of the land, partially protected by a low ledge of rocks, entirely inadequate for the terminus of a great work like the proposed canal, and incapable of answering the commonest requirements of a port. To remedy this deficiency, it was proposed to construct an artificial harbour of 34 acres area, by means of moles and jetties in the sea and extensive excavations in the land. If, as supposed, the excavations here would be in sand, it would be obviously almost impossible to secure proper foundations for the immense sea-walls and piers which the work would require. If in rock, as seems most likely, the cost and labour would almost surpass computation. Assuming the excavations to be in earth and sand, Colonel Childs estimated the cost of these improvements at upwards of L.540,000.

Returning now to the lake, and proceeding from 17 feet depth of water, opposite the mouth of the Rio Lajas, in the direction of the outlet of the lake at San Carlos, there is ample depth of water for vessels of all sizes for a distance of about 51 miles, to a point half a mile south of the Boceas Islands, where the water shoals rapidly to 14 feet; for the remaining $5\frac{1}{2}$ miles to San Carlos, the depth averaging only 9 feet at low, and 14 feet at high water. For this distance, therefore, an average under-water excavation of 8 feet in depth would be required to carry out the plan of a canal of 17 feet deep. But if the lake were kept at high level, the under-water excavation would have an average of only about 3 feet. Colonel Childs proposed to protect this portion of the canal by rows of piles driven on each side, and supposed that when the excavation should be completed, there would be sufficient current between them to keep the channel clear.

We come now to the division between Lake Nicaragua and the Atlantic through or along the Rio San Juan. Colonel Childs carried a line of levels from the lake at San Carlos to the port of San Juan, and found the distance between those points to be $119\frac{3}{4}$ miles, and the total fall from the level of high-water in the lake to that of high-tide in the harbour, $107\frac{1}{2}$ feet. From San Carlos to a point half a mile below the Serapiqui River, a distance of 91 miles, Colonel Childs proposed to make the river navigable by excavating its bed, and by constructing dams, to be passed by means of locks and short canals; the remaining 28 miles to be constructed through the alluvial delta of the San Juan, inland, and independently of the river. Of the whole fall, $62\frac{1}{2}$ feet occur on that portion of the river which it was proposed to improve by dams, and on which there were to be eight locks; and the remaining 45 feet on the inland portion of the work, by means of six locks,—fourteen locks in all, each with an average lift of nearly 8 feet. It was proposed to place the first dam, descending the river, at the Castillo rapids, 37 miles from the lake, and to pass the rapids by means of a short lateral canal. By means of this dam the river was to be raised at that point $21\frac{1}{2}$ feet, and the level of Lake Nicaragua 5 feet above its lowest stage; or, in other words, kept at high-water mark, to avoid the extensive submarine excavations which would be necessary to enable vessels to enter the river. The fall at this dam would be 16 feet. The other dams were to be four of 8 feet fall, one of $13\frac{1}{2}$ feet, and another of $14\frac{1}{2}$ feet. Between all of these it was found there would be required more or less excavation in the bed of the stream, often in rock. Colonel Childs also proposed to improve the harbour of San Juan by means of moles, &c., and also to construct an artificial harbour or basin, in connection with it, of 13 acres area. As regards the amount of water passing through the San Juan, it was found that at its lowest level, June 4, 1851, the discharge from the lake was 11,930 cubic feet per second. The greatest rise in the lake is 5 feet. When it stood 3.43 feet above its lowest level, the flow of water in the river, at San Carlos, was 18,059 cubic feet per second, being an increase of upwards of 50 per cent. Supposing the same ratio of increase, the discharge from the lake at extreme high-water would be upwards of 23,000 cubic feet per second. The river receives large accessions from its tributaries, which, at the point of divergence of the Colorado channel, swell the flow of water to 54,380 cubic feet per second; of which 42,056 cubic feet pass through the Colorado channel, and 12,324 cubic feet into the harbour of San Juan.

The cost of the work was estimated by Colonel Childs as follows: Nicaragua.

Eastern division (from Port of San Juan to lake),	L.2,604,655
Central division (through lake),	213,682
Western Division (from lake to Pacific),	2,895,126
	<hr/> L.5,713,463
Add for contingencies 15 per cent.	857,019
Total estimated cost	<hr/> L.6,570,482

The charter of the company, under the auspices of which Colonel Childs was sent to Nicaragua, stipulated that the canal should be of dimensions sufficient "to admit vessels of all sizes." A canal therefore, such as the proposed, but 17 feet deep, and 118 feet wide at the surface of the water, could not meet the requirements of the charter, nor be adequate to the wants of commerce. To pass freely large merchantmen and vessels of war, a canal would require to be at least 30 feet deep, with locks and other works in proportion, which would involve at least three times the amount of excavation, &c., of the work proposed above, and a corresponding augmentation of cost. A canal so small as to render necessary the transhipment of merchandise and passengers is manifestly inferior to a railway, both as involving, in the first instance, greater cost of construction, and, in the second place, greater expense in working, with less speed.

The surveys and estimates of Colonel Childs were submitted to the British government, and by it referred for report to Mr James Walker, civil engineer, and Captain Edward Aldrich, Royal Engineers. The report of this commission, proceeding on the assumption that the plans, measurements, &c., of Colonel Childs were correct, was on the whole favourable. It, however, suggested that the item of "contingencies" in the estimate should be increased from 10 to 25 per cent. Of all the works of the proposed navigation, it pronounces the Brito or Pacific harbour as least satisfactory. "Presuming the statements and conclusions of Colonel Childs to be correct, the Brito harbour is, in shape and size, unworthy of this great ship navigation, even supposing the Pacific, to which it is quite open, to be a much quieter ocean than any we have seen or have information of." Subsequently the plans and reports were laid before a committee of English capitalists, with a view to procure the means for the actual construction of the work. This committee, after a patient investigation, declined to embark in the work, or to recommend it to public support, on the ground—1st. That the dimensions of the proposed work were not such as, in their opinion, would meet the requirements of commerce; 2d. That these dimensions were not conformable to the provisions of the company's charter; 3d. That supposing the work not to exceed the estimated cost of L.6,500,000, the returns, to meet the simple interest on the investment, at 6 per cent., would require to be at least L.390,000 over and above its current expenses; or to meet this interest, and the percentage to be paid to Nicaragua, not less than L.473,000 over and above expenses; or, allowing L.200,000 per annum for repairs, superintendence, cost of transportation, &c., then the gross earnings would require to be L.680,000 4th. Putting the toll at 12s. 6d. per ton, the collection of this revenue would involve the passage of upwards of 1,000,000 of shipping per annum; 5th. That not more than one-third of the vessels engaged in the oriental trade could pass through a canal of the proposed dimensions, even if the route which it would open were shorter than that by way of Cape of Good Hope, instead of being more than 1000 miles longer to Calcutta, Singapore, and other leading ports of British India; 6th. That the heavy toll of 12s. 6d. per ton on ships would generally prevent such vessels as could do so from passing the canal, inasmuch as on a vessel of 1000 tons the aggregate toll would be L.625, or more than the average earnings of such vessels per voyage; 7th. That a work of the dimensions proposed, under the present condition of commerce, would not attract sufficient support to defray the cost of repairs and working, and could not therefore be safely undertaken by capitalists. Upon the publication of this report, the canal company obtained the privilege of opening a transit by steamers and carriages through Nicaragua, the project of a canal was definitively abandoned, and the charter allowed to be forfeited for non-user. It was obtained in 1849, for a period of eighty-five years from the completion of the work, for which twelve years were allowed; the canal was to revert to the state at the expiration of the charter; the state to receive for the first twenty years after the opening of the work 20 per cent. annually of its net profits, and thereafter 25 per cent. Other onerous restrictions were imposed, of a nature to deter so large an investment of capital as the work would require; although in these respects the charter was much more liberal than any of those which had previously been conceded for the same purpose. By the terms of the Bulwer-Clayton convention of 1850, Great Britain and the United States have defined

Nicaragua the principles which they agree should apply to an inter-oceanic canal, wherever and whenever constructed:—

Niccolo
Pisano.

1. That neither Great Britain nor the United States will ever obtain or maintain for itself any exclusive control over such work, nor erect fortifications commanding it, or in its vicinity, or make use of its influence or relations with the countries through which such canal may pass, to secure exclusive privileges for itself or its subjects in the same.

2. Neither party to capture or detain the vessels of the other while passing through the canal, or within — leagues of its extremities.

3. To protect the capitalists undertaking the construction of the canal from "unjust interference, seizure, and violence."

4. To use their influence to facilitate the work, and their good offices to procure the establishment of a free port at each extremity of the same.

5. To guarantee the neutrality of the canal so long as its proprietors shall not make unfair discriminations on vessels in transit, or impose unreasonable tolls.

6. To extend the same general protection to every practicable communication, whether canal or railway, across the isthmus of Central America.

The first opportunity for a compliance with the provisions of this convention was afforded in 1856, in which year Great Britain entered into a treaty with Honduras, for the protection and guarantee of the Honduras Inter-oceanic Railway, in strict conformity with the principles here laid down.

The construction of a ship-canal between the oceans through Nicaragua is unquestionably within the range of engineering feasibility; but it can be as safely affirmed that, with the present requirements of commerce, and under the laws which govern the use of capital, it is not likely to be seriously undertaken. The assumption upon which most of the speculations regarding the utility of such a work are founded, viz., that it would shorten the distance between the ports of Europe and those of Asia in general, is erroneous, as will appear from the following table:—

	Via Cape of Good Hope.	Via proposed Canal.	Net Loss.	Net Gain.
<i>From England</i>	Miles.	Miles.	Miles.	Miles.
To Canton.....	12,900	13,800	900	...
Calcutta.....	11,440	15,480	4040	...
Singapore.....	11,880	15,120	4240	...
Sidney, via Torres Straits.....	14,980	12,550	...	2320
<i>From New York</i>				
To Canton.....	14,100	11,820	...	3280
Calcutta.....	12,360	13,680	1320	...
Singapore.....	12,700	1,420	...	1280
Sidney.....	15,720	9,480	...	5240

It will be observed that the sole advantage which the canal would afford to Great Britain, as regards the East, would be a saving in distance (equally attainable by a railway across the isthmus) of 2320 miles in communicating with Australia. As regards the Sandwich Islands and the western coast of America, the gain in distance, both to England and the United States, would be considerable, as shown in the subjoined table:—

	Via Cape Horn.	Via proposed Canal.	Gain.
<i>From England</i>	Miles.	Miles.	Miles.
To Valparaiso.....	8,700	7500	1200
Callao.....	10,020	6800	3220
Sandwich Islands.....	13,500	8640	4860
<i>From New York</i>			
To Valparaiso.....	8,580	4860	3720
Callao.....	9,900	3540	5360
Sandwich Islands.....	13,200	6300	6900

(E. G. S.)

NICASTRO, a town of Naples, province of Calabria Ultra II., on a slope of the Apennines, 19 miles S. by E. of Cosenza. It is meanly built, but walled, and defended by a castle, in which Henry, eldest son of the Emperor Frederick II., was confined for having embraced the Guelph party against his father. The town is the see of a bishop, contains several churches and convents, and has some trade in oil. Pop. 6600.

NICCOLO PISANO, or DI PISA. See PISANO.

NICE (Ital. *Nizza*, anc. *Nicæa*), a seaport-town of the Sardinian States, capital of the province and administrative division of the same name, is built on a small plain between the Alps and the Mediterranean, 96 miles S. by W. of Turin. It is traversed by the River Paglione, and consists of three parts, one of which, called the Quartier de la Croix de Marbre, stands to the W. of the Paglione, and is the principal residence of strangers in Nice. This part of the town derives its name from a marble cross, built here to commemorate the reconciliation of Charles V. and Francis I. in 1538, through the intervention of Pope Paul III. Near this cross stands an obelisk in memory of the two visits of Pius VII. in 1809 and 1814. In this quarter of Nice there is also a large public square, surrounded with fine buildings, and a handsome quay, which runs along the side of the river. The other two parts of the town stand on the E. side of the Paglione, and are separated from each other by a hill of limestone 800 feet high, which formerly had a castle on the summit, but is now laid out in public walks commanding a wide and beautiful prospect. Between the river and the castle-hill is the old town, consisting of several streets of no great breadth, and including, close under the hill, a dirty locality, which is the oldest part of the whole town. The quarter of the port on the other side of the castle-hill is chiefly inhabited by seafaring people, and was once a mean and crowded place, but it has recently been much improved. The harbour is small, but capable of admitting vessels drawing 15 feet of water, and is protected by two moles, one of which has at its extremity a lighthouse and battery. The entrance is difficult in stormy weather, and it is not well adapted for a harbour of refuge. The public buildings of Nice are by no means remarkable; the principal is the cathedral, an edifice in the common Italian style of the seventeenth century. There are numerous other churches, but none of them are of any great architectural merit. The national college (which has a botanic garden), the public library and zoological museum, the theatre, baths, convents, and hospitals, complete the list of the important public institutions of the town. The climate of Nice has been much praised, and although its advantages may perhaps have been exaggerated, there can be no doubt that it is remarkable for its mildness and salubrity. It is subject to no sudden variations of temperature; the changes of season occur with considerable regularity, and the differences in heat from one month to another rarely exceed 2° or 3° Fahrenheit. The mean temperature of the spring at Nice is about 64°; of the summer, about 74°; of the autumn, about 55°; and of the winter, about 50°; while the greatest heat in summer is rarely above 84°, and the cold in winter seldom below 32°. The clearness of the atmosphere during the most part of the year is one of the greatest advantages of the place; but the cold blasts of the *vent de bise*, as it is called, which prevails in February, are both disagreeable and injurious to invalids. The town contains several silk, cotton, paper, and oil mills; and there are also manufactories of tobacco, snuff, perfumery, soap, leather, &c. The trade of the place is in these articles, and in wine, oranges, and other fruits. The number of vessels that entered the port in 1846 was 2609; tonnage, 155,764: those that cleared in the same year, 2583; tonnage, 153,635. Nice was originally founded by the Phœceans of Marseilles, and fortified by them against the native Gallic tribes. For a long time it remained subject to its parent city; and even after both were included in the Roman empire, Nice was still in a subordinate position, and does not seem to have attained to any importance under the Roman sway. The ancient town did not occupy precisely the same site as the modern; but stood further up the mountains, where there are some remains both of this town and of Cemenelum (the modern *Cimies*). In the middle ages Nice was

Nice.

Nice,
Council of.

the capital of a small independent county, and at that time it stood on the left bank of the river, close round the foot of the castle-hill. It afterwards came into the possession, first of the counts of Provence, and then of the kings of Naples; and was sold in the end of the fourteenth century by Ladislaus to Amadeus VII. of Savoy, in whose house it still remains. The town has been taken several times by the French, and was annexed by them to the republic, and made the capital of the department of the Maritime Alps in 1791; but it was restored to Sardinia in 1814.

The administrative division, of which Nice is the capital, is bounded on the N. by Piedmont, from which it is separated by the Alps; E. by the division of Genoa; S. by the Mediterranean; and W. by France. The higher parts of the mountains in the north are covered with forests of excellent timber trees, and the lower slopes and valleys, though unfit for cultivation, afford excellent pasturage. Towards the south the soil is fertile, and produces maize, barley, and wheat; besides olives, figs, grapes, oranges, and other fruits. Cattle are reared to a considerable extent; bees are also kept; and there are good fisheries along the coast. The climate is mild and dry, being sheltered from the north winds by the Alps. It is divided into three provinces, as follows:—

	Area in sq. miles.	Pop. in 1848.
Nice.....	1178	118,377
Oneille	173	60,072
St Rémo.....	263	64,541
Total	1614	242,990

The town of Nice is remarkable as the birth-place of Massena, one of the most famous of Napoleon's generals. Pop. 33,811.

NICE, or *Nicæa*, *The Council of*, was the earliest as well as the most important of the œcumenical councils held in the Christian church. It was convened at Nicæa, a town in Bithynia, A.D. 325, by command of the Emperor Constantine, to settle the controversy which had recently sprung up in the church respecting the doctrines of Arius, presbyter of the Church of Alexandria. In an assembly of the presbyters held some time previously, Alexander, Bishop of Alexandria, maintained that the Son was not only equal in dignity with the Father, but was also of the same essence. Arius charged the doctrine with Sabellianism, and boldly assumed the opposite extreme. "If," said he, "the Father begat the Son, the begotten had a beginning of existence; hence it is plain, that there was a time when he was not." (Socrates, *Hist. Eccles.*, lib. i., c. 5.) Not a few openly sided with Arius; and the upshot of it was that the heretic had his doctrines condemned, and

Nice,
Council of.

himself and nine of his adherents excommunicated. The quarrel raged fiercely on both sides, and the emperor mildly attempted a reconciliation between the orthodox bishop and the heretical presbyter. His efforts proved unavailing, and in order effectually to silence the disputants, he convened the council in question. Bishops flocked to it from all parts of Christendom, particularly from the East, until their number amounted to 318. The assembly was honoured by the imperial presence; and the venerable Fathers began by accusing each other. Constantine, who seems to have displayed much good sense on the occasion, magnanimously burnt these accusations without reading them; and exhorting the disputants to peace and harmony, bade them open deliberations. Debate waxed keen; words ran high; whole quivers of logic and treasures of learning were exhausted; but unanimity was as distant as ever. The orthodox party, after selecting those passages of Scripture which bear upon the divinity of the Son of God, extracted from them the conclusion that the Son was of *the same substance* (*ὁμοούσιος*) or consubstantial with the Father. Eusebius of Nicomedia proposed a creed in behalf of the Arians, but the council pronounced it heretical, and appointed Hosius of Corduba to draw up one in its stead. This document, agreeing substantially with the Nicene Creed of the present day, received the sanction of the council and the approbation of the emperor. Deposition, excommunication, and exile were the penalty of non-acquiescence. Arius stood firm, and suffered the consequences. Twenty of the twenty-two Arian bishops, whose ingenuity was nicer than their conscience, subscribed to the creed, by foisting an iota into the Platonic epithet of their opponents, and thus converting *ὁμοούσιος* (of the *same substance*) into *ὁμοιούσιος* (of *similar substance*). Secundus of Ptolemais and Theonas of Marmarica declined to stoop to such courtly duplicity, and boldly reprovved Eusebius for his dishonesty.¹ (See *ARIUS*.)

The *Nicene Creed*, as at present recited in the communion service of the Church of England, agrees precisely with the creed drawn up at this council, with the exception of the part which asserts the divinity of the Holy Ghost. This addition was made, A.D. 381, at the council of Constantinople; and the words "and the Son," coming after "who proceedeth from the Father," were inserted by the Spanish bishops in A.D. 447, and admitted after some hesitation by those of Rome in A.D. 883.

The *Second Council of Nice* was held by the Empress Irene and her son Constantine in A.D. 787, and declared the worship of images to be lawful.

(See *The Greek Ecclesiastical Historians of the first Six Centuries of the Christian Era*, 6 vols., London, 1853; *Some Account of the Council of Nicæa*, by John Kaye, D.D., London, 1853; Gieseler's *Ecclesiastical History*,

¹ New and interesting information respecting the Council of Nice has recently been fallen upon in a Syrian fragment in the British Museum (Add. MSS., No. 14,528), written in A.D. 501, and obtained from the Nitrian Desert in Egypt a few years since. The Syrian text of this fragment, with a translation and notes, and some account of the MS. volume from which it has been obtained, was published, under the title *Analecta Nicæna*, by B. Harris Cowper, London and Edinburgh, 1857; but the impression was limited to 250 copies. Among other curious pieces printed in this tract are,—(1.) The Epistle of Constantine the King summoning the Bishops to Nice, referred to by Eusebius in his Life of that monarch, but hitherto regarded as lost; (2.) The Decree of Constantine against the Arians, given by Socrates in his Church History, and found in other Syrian MSS.; (3.) The Nicene Creed; (4.) The Creed of Constantinople; (5.) The Subscribers to the Nicene Council, the most ancient, curious, and complete list yet brought to light; (6.) Titles of the Canons of Nice; (7.) The Colophon; (8 and 9.) Fragments from another MS. in the same collection, in which the presidency of the Nicene Council seems to be assigned to Alexander of Alexandria; (10 and 11.) Canons VI. and VII. of the Nicene Council, from which it will be seen, that no allusion whatever is made to any superiority of the Roman See different from that of the others mentioned; (12.) Colophon. The following is a copy of the long-lost letter of Constantine, as translated by Mr Cowper:—"An Epistle of Constantine the King, summoning the Bishops from Ancyra to Nice.—That there is nothing more honourable in my sight than religion, is, I believe, manifest to every man. Now, because the Synod of Bishops at Ancyra, of Galatia, consented formerly that it should be so, it hath seemed to us now on many accounts, that it would be well for it to be assembled at Nice, a city of Bithynia, because the Bishops of Italy, and of the rest of the countries of Europe, are coming, and because of the excellent temperature of the air, and because I shall be at hand as a spectator and participator of what is done. Wherefore I signify to you my beloved brethren, that ye, all of you, promptly assemble at the city I spoke of; that is, at Nice. Let every one of you, therefore, diligently inquire into that which is profitable, in order that, as I before said, without any delay we may speedily come to be a present spectator of those things which are done by the same. God keep you, my beloved brethren." (P. 21.)

Nicephorus. Edinburgh, 1846; Neander's *History of the Church*, 8 vols., London, 1850-52; and Landon's *Manual of Councils*.)

NICEPHORUS I., Emperor of Constantinople, was a native of Seleucia, and rose by the favour of the Empress Irene, and by his own hypocritical intrigues, to the high office of *logotheta*, or minister of finances. In 802 A.D., assisted by the ungrateful treachery of some eunuchs who were high in favour with the queen, he seized upon the purple. After Nicephorus had consolidated his power by the most cruel measures, he despatched a letter to the caliph Harun-al-Raschid, demanding back the tribute-money paid him by the Empress Irene. The caliph replied by devastating the plains of Phrygia; and, after various fortune, the death of Harun-al-Raschid in 809, left Nicephorus to direct a system of universal butchery against the Bulgarians. He was surprised and slain in 811. (See CONSTANTINOPOLITAN HISTORY.)

NICEPHORUS II., surnamed *Phocas*, Emperor of Constantinople, was the descendant of a warlike race, and was born about 912 A.D. He was brought up in the camp, and rose by his own merit through the different grades of promotion until he was appointed *magnus domesticus* in 954. His military genius was first displayed in several expeditions against the Saracens during 956 and 958; but not until 959 did it appear in its full splendour. He then proposed to the young emperor Romanus II. the bold design of taking Crete, which had been for more than a hundred years the impregnable stronghold of a desperate gang of Arabian pirates. The enterprise received the approval of the emperor; and in 960 Nicephorus was laying vigorous siege to the massive fortifications of Candia, the capital of the Cretans. Complete success was achieved in the following year. He captured the city, and along with it the whole island; the inhabitants yielded to his proselytizing zeal, and received baptism; and the long-extinct honours of a triumph were revived to reward him on his return to Constantinople. But in the full enjoyment of his renown, the conqueror did not forget to follow up his success. Setting out at the head of a mighty army in 962, he forced his way through the narrow passes of Mount Amanus, and entering Syria, compelled the principal cities to throw open their gates. He was advancing in his career of victory towards the River Euphrates, when intelligence reached him, in 963, of the death of the Emperor Romanus. The thought of aspiring to the vacant throne now seized him, and changed the generous and free-hearted warrior into the wily votary of ambition. His designs were executed with a soldier-like promptness and decision. He first procured for himself the appointment to the supreme command of the oriental armies during the minority of the infant princes; then he gained over to his interest the officers and soldiers; and at length he married the deceased emperor's wife—the infamous Theophano—and assumed the title of Augustus. But Nicephorus was not so popular on the throne as in the camp. Though he reappeared at the head of his armies, and yearly made a successful invasion against the Saracens, yet the heavy taxes which were levied to support these expeditions more than counterbalanced, in the public estimation, the glory gained by them. The emperor came to be generally accused of hypocrisy and avarice. His fickle wife in course of time joined the number of his enemies, and began to plot his death. One of her paramours, John Zimisces, a brave and able general of the imperial armies, was induced to undertake the office of assassin. On a December night in 969, he crossed in a small boat from the Asiatic side of the Bosphorus, and was admitted by a rope-ladder into the palace. There a band of cut-throats, putting themselves under his direction, burst into the royal apartment, and murdered Nicephorus as he started from sleep. The arch-assassin immediately afterwards married Theophano, and succeeded to the purple.

VOL. XVI.

NICEPHORUS III., surnamed *Batoniates*, Emperor of Constantinople, claimed to be a descendant of the Roman Fabii. He served in the imperial forces, and in 1078 had risen to be commander of the army in Asia. In that year, aided by the Sultan Soliman, he raised the standard of revolt against the Emperor Michael VII. The discontented populace of Constantinople received him with enthusiasm; the weak emperor resigned his crown to retire into a monastery; and Nicephorus ascended the throne on the 25th March 1078. The new reign was inaugurated with a cruel and narrow-minded policy which soon brought it to a close. The rebel generals Ursel, Bryennius, and Basilacius, who were soon afterwards defeated and captured, had their eyes put out, and were reserved for further cruelties. Even the brave Alexis Comnenus, the conqueror of these, became at length the object of the emperor's ever-wakeful suspicions, and was forced to flee from the ungrateful court. It was this injustice that caused the downfall of Nicephorus. Alexis was proclaimed emperor by the indignant soldiery, and Nicephorus, resigning the crown retired to end his days in a monastery.

NICEPHORUS *Callistus*, an ecclesiastical historian, was born towards the close of the thirteenth century, and died about 1350. In his thirty-sixth year he was engaged at Constantinople in the composition of an *Historia Ecclesiastica*, founded on the narratives of Eusebius, Socrates, Sozomen, Theodoret, Evagrius, and others. It is filled with absurd fables; and of the twenty-three books only eighteen are extant. They were published in Greek and Latin, in 3 vols. fol., Paris, 1630.

NICEPHORUS, Patriarch of Constantinople, was the son of Theodorus, one of the imperial secretaries of Constantius Copronymus, and was born in 758. From his father he inherited a zeal for image-worship, which gave a colour to all the principal events of his life. He was present as imperial commissary at the Nicene Council of 787, and raised his voice against the Iconoclasts. This spirit of partizanship only became more intense when, in 806, he was raised from the condition of a monk to the patriarchate of Constantinople. An edict against the worship of images was passed in 814 by Leo the Armenian; but neither entreaties nor menaces could prevail upon Nicephorus to assent to it. He rather preferred to be deposed in the following year, and to spend the rest of his days in a convent. His death took place in June 828. Of his works, which are written in Greek, the best is his *Breviarium Historicum*, a compendious history of the period extending between 602 A.D. and 770. It was published, with a Latin version and notes, in 8vo, Paris, 1616; and was reprinted in the *Corpus Historiæ Byzantine*. A Life of the Patriarch Nicephorus, by his contemporary Ignatius, has been translated into Latin, and inserted in the *Acta Sanctorum*.

NICHOLAS I., the earliest of the Roman pontiffs who bore that name, was elevated from the rank of a deacon to the papal chair in April 858. One of his first endeavours was to realize the alleged supremacy of the popedom. Assuming as his authority the new ecclesiastical code, now known by the name of the Pseudo-Isidorian Decretals, he asserted that the Pope, as the representative of St Peter, was the head of Christ's body the church; that the bishops, as members of that body, had no other law than his will; and that all offences throughout Christendom should be liable to be arraigned before his tribunal. These principles, so boldly asserted, were as boldly carried into practice. Taking part in the dispute concerning the patriarchate of Constantinople between Ignatius and Photius, he excommunicated the latter in 863, and maintained a fierce controversy with the Emperor Michael III. in support of this exercise of his ecclesiastical authority. He also interfered, during the same year, with the attempt of Lotharius, King

Nicephorus
Nicholas

Nicholas. of Lotharinga, to divorce his wife Thietberga, and to marry his concubine Waldrade. The Emperor Louis, the brother of Lotharius, bent upon forcing Nicholas to withdraw his interference, marched into Rome at the head of an army. But the fervent and long-continued devotions and the saint-like composure of the Pope soon awed the superstitious potentate into submission and reconciliation. Nicholas continued for the rest of his life to vindicate successfully the absolute ecclesiastical supremacy of the see of Rome. He died in 867. His letters, amounting to about a hundred, and treating of church doctrine and discipline, were published in folio, Rome, 1542. The rest of his works were inserted in Colet's *Collection of Councils*.

NICHOLAS II., whose original name was Gerhard, was promoted from the bishopric of Florence to the Papal chair in 1058. Under the guidance of the able and ambitious Hildebrand, who was afterwards supreme pontiff under the title of Gregory VII., he proceeded to establish his authority, and to provide for the increased stability and influence of the Papal see. John, bishop of Velletri, who had been set up as a rival Pope, under the name of Benedict X., was forced to submit. A law was passed in 1059 which took the power of choosing the supreme pontiff out of the hands of the Roman mob, placed it in the hands of the cardinal bishops and priests, and restricted the elective influence of the emperor and the citizens of Rome to a mere assent. The new Pope was even daring enough to claim the possession of Apulia, Calabria, and Sicily, to give them in fief to Robert Guiscard, a Norman, and thus to establish the civil supremacy of the Roman see over that territory which was afterwards known as the kingdom of Naples. Nicholas was further engaged in enforcing a stricter morality upon the priests, when he died in July 1061.

NICHOLAS III., whose original name was Giovanni Gæstani, succeeded John XXI. in 1277. His descent from the noble family of the Orsini, his tact, and his energy rendered him a powerful upholder of the despotism of the Roman see. He obtained from the Emperor Rudolph several grants of territory in Italy, and punished the haughty insubordination of Charles of Anjou, King of Naples, by depriving him of the dignity of senator of Rome. Other great projects were occupying his attention, when a stroke of apoplexy brought his career to a close in 1280.

NICHOLAS IV., originally known by the name of Jerome of Ascoli, was raised from the bishopric of Palæstrina to the pontifical chair in 1288. Though sometimes guilty of favouritism, he was characterized in general by an enlightened zeal for the welfare of the church. He was a liberal patron of theological as well as civil learning; he sent forth missionaries as far as China; and he used his utmost efforts to revive the spirit of the Crusades. It is said to have been the final expulsion of the Christians from the Holy Land that hastened his death in 1292.

NICHOLAS V., whose real name was Tommaso Da Sarzana, succeeded Eugenius IV. in 1447. The meek probity of his character did not suffer him to adopt the usual aggressive policy of the popedom; and his literary tastes induced him to seek for that general peace which is so favourable to the advancement of learning and civilization. The consequence was, that in 1449 the anti-Pope Felix V., who had for several years maintained a schism in the church, tendered his submission; and about the same time the Italian states, discontinuing their accustomed broils, relapsed into tranquillity. The learned pontiff was thus enabled to devote the rest of his life to the promotion of polite letters. Under his rule Rome became the favourite seat of learning. The most liberal patronage was extended to literary merit; wits and scholars from all parts of Europe thronged the pontifical court; a library, containing famous manuscripts of the Christian fathers and the great Greek authors, began to be formed in the Vatican; and messen-

gers were constantly arriving from all the countries of Christendom with new treasures for its shelves. This rapid advance towards general enlightenment was prematurely interrupted by the death of its wise and munificent promoter in 1455.

NICHOLAS, St., one of the Cape Verde Islands, is situated in N. Lat. 16. 42., W. Long. 24. 20. Its shape is irregular; and its area is 115 square miles. There are two remarkable mountains in the island, one of which, near the centre, has the form of a sugar-loaf, and is called the Peak of Trade. The soil is fertile, but there is not much wood or water. There are several not very good harbours on the south coast; but the principal trade is carried on at Grand or St George Bay, at the western extremity. Pop. 5418.

NICHOLS, JOHN, a writer of literary anecdotes, was born at Islington in 1745, and at the age of twelve became an apprentice to the famous printer William Bowyer. His taste for literature, his industry, and his business talents soon raised him high in the favour of his master. He was taken into partnership in 1766, and succeeded to the entire business in 1777. It was then that the aptitude for curious biographical and topographical research by which he was specially characterized began to appear to the world. In course of time it found full scope in the *Gentleman's Magazine*, of which he became editor and part proprietor in 1778; in his *History of Leicestershire*, which he began in 1795, and completed in 4 vols. fol. in 1815; and in a series of rare literary and antiquarian works which he continued to edit and print. But its chief result was the *Literary Anecdotes of the Eighteenth Century*, in 9 vols. 8vo, 1812-15. This work was a rich biographical treasury, containing numerous traits of eminent men of every stamp, and much correspondence, judiciously selected and accurately given. But Nichols had not yet exhausted his stock of this sort of historical materials. In 1817-22, he published *Literary Illustrations of the Eighteenth Century, intended as a Sequel to the Literary Anecdotes*, in 4 vols. A fifth volume was in the press, and a sixth in preparation, when the author died in 1826. The former was published in 1828, and the latter in 1831. A seventh volume appeared in 1848, and an eighth in 1858, both by his son, John Bowyer Nichols, who succeeded to his father's business. (See *Gentleman's Magazine* for 1826.)

NICHOLSON, WILLIAM, an eminent chemist and mechanic, was born in London in 1753. His early years were spent in commercial pursuits, but he soon abandoned that occupation for the more congenial walk of scientific research. He opened a school in the metropolis in 1775, which he continued to conduct with great success for a long series of years. Meanwhile he prosecuted mechanical invention and scientific inquiry with great zeal. Besides English translations of the chemical works of Fourcroy, Chaptal, &c., he wrote numerous treatises on natural philosophy and chemistry, and was unquestionably the most eminent philosophical journalist of his day. His most valued works are his *Dictionary of Chemistry*, 2 vols. 4to, 1795; and his *Journal of Natural Philosophy, Chemistry, and the Arts*, 5 vols. 4to, 1797-1802, of which a new series appeared in 36 vols. 8vo, 1802-14. He invented an aræometer and other instruments, but so impoverished himself by these pursuits that he was imprisoned for debt. He died in London in June 1815. (See *DISSERT. SIXTH*, chap. vii.)

NICIAS, an Athenian statesman, son of Niceratus, chosen by the aristocracy and the more moderate of the democratical party, as the fittest person to lead the councils of the commonwealth after the death of Pericles, in 428 B.C. He was also a favourite with the people, as he was liberal of his wealth for their gratification, and ever ready to assist the distressed. He resembled Pericles in the conservative nature of his foreign policy, and in the thorough incorruptibility of his character. The rigid decorum and strict devout-

Nicholas, St.
||
Nicias.

Nicias.

ness of his character have been severely ridiculed by Aristophanes, in the *Equites*, as nothing better than timidity and superstition. The first matter in which Nicias and Cleon took opposite views was the punishment that ought to be inflicted on the inhabitants of Mitylene for their rebellion. Cleon proposed and carried a decree for putting every man to death, and for reducing the women and children to slavery. This monstrous proposition was opposed by all the influence of Nicias, but passed in spite of its evident injustice. Nicias led several expeditions, and was always successful, because, as Plutarch says, he selected those commands where success was nearly certain, although the glory might indeed be small. He took the islet called Minoa, at the mouth of the harbour of Nisæa, the seaport of Megara; and he plundered the coast of Bœotia. He commanded the fleet, 425 B.C., at the time that the island Sphacteria was blockaded by the Athenians, and willingly gave up the command to Cleon, who exclaimed that if he were in that station he would engage to subdue the island within twenty days, and bring the garrison prisoners to Athens. To the great surprise of all parties, Cleon succeeded in the enterprise (Thucydides, iv. 28). The following year we find Nicias commanding an expedition, which was directed against the island of Cythera, an important appendage of the Lacædemonian territory, and which Nicias took without much difficulty. After the death of Cleon at Amphipolis, 422 B.C., there was a strong inclination on both sides to bring the war to a close; and as Nicias was the most active in promoting the measure, it was usually called the Niceian peace. The fundamental principle of the treaty was, that each party should restore what had been taken in war, except that Nisæa was reserved to Athens, in consideration of the refusal of the Thebans to surrender Plataea. It was concluded for fifty years, 421 B.C. (Thucydides, v. 18.) At this time Alcibiades began to occupy himself with public affairs; and wishing to ingratiate himself with the popular party, he took the opposite side to Nicias in almost every question. It was so in respect to the peace; and as there were some articles liable to be disputed, Alcibiades soon managed to embroil matters, and war again broke forth in all its original fury, 418 B.C. An expedition to Sicily was next proposed by Alcibiades; and although it was strongly opposed by Nicias, the decree was passed, and Nicias was appointed, along with Lamachus and Alcibiades, 415 B.C., to command the troops. Matters were conducted with various success; but the Athenians were at length completely defeated, and Nicias fell into the hands of the Syracusans. The mob demanded his life; and although Gylippus, the Syracusan general, exerted himself to save Nicias, it was without success. When Nicias and his colleague Demosthenes heard the sentence which had been passed against them, they anticipated their fate by putting themselves to death, in the year 413 B.C. (Thucydides, vii.; Plutarch; Diodorus Siculus; Thirlwall's *History of Greece*, vol. iii.; Grote's *History of Greece*, vols. vi., vii.)

NICIAS, a great Greek painter, was the son of Nicomedes, and flourished at Athens about the fourth century B.C. He studied his art under Antidotus, a pupil of the celebrated Euphranor. One of his earliest undertakings seems to have been the painting of the marble statues of Praxiteles, a process which the Romans called *circumlitio*. But, though eminently successful in this engagement, he soon turned his hand to the more legitimate branches of his art. All his energies became absorbed in the executing of pictures. He devoted great attention to colouring, and was the first painter who used burnt ochre; he studied the subjects of his pieces with the minute care which the dramatic poet bestows upon his plot; and he was often so engrossed with his work that he forgot to take his meals. The result of such painstaking industry was, that the artist soon grew famous for the graceful de-

sign, the beautiful colouring, the exquisite light and shade and the fine general effect of his pictures. His masterpiece was entitled *Nekula*, and was a representation of the infernal regions taken from the description in the *Odyssey*. Ptolemy, King of Egypt, offered sixty talents for it; but the painter chose rather to present it to his native Athens. Such a patriotic liberality seems to have combined with his genius in gaining for him the esteem of his fellow-citizens; for, at his decease, he was honoured with a public funeral, and was interred in the cemetery consecrated to the great Athenian dead, on the road between the city and the academy.

The other important works of Nicias, as enumerated by Pliny, were a Nemea, a Hyacinthus, a Bacchus, and an Alexander (Paris), all at Rome. (A minute account of Nicias is given in the *English Cyclopædia*.)

NICOBARS, a cluster of islands in the Indian Ocean, lying between N. Lat. 6. 40. and 9. 20., and E. Long. 93. 3. and 94. 13., and inhabited by Malays. A settlement was formed here by the Danes in 1756, but abandoned by them in 1768. In the year 1840 the whaler Pilot, of London, was seized by pirates infesting the Nicobars. At this period the sovereignty of these islands was claimed by the Danes. Evidence subsequently obtained, left little room for doubt, that, in several instances, the crews of British vessels had been murdered, and the vessels scuttled and sunk by the islanders. Measures were taken to give notoriety to these circumstances. In 1848 the Danish government came to the determination to abandon all claim to sovereignty over the Nicobars. Some years later, certain residents of Chittagong made a representation to the Indian government regarding two brigs which had sailed for the Nicobars in the year 1852. Neither of them had since been heard of, and a strong presumption existed that both had been cut off by savages. Captain Dicey, of the steamer *Tenasserim*, was therefore despatched to the Nicobars for the purpose of inquiring into the fate of the missing vessels; and the report of this officer, the official authorities observes, "leaves no doubt that two vessels, one of them English, have recently been destroyed, and their crews murdered by the inhabitants of the Nicobars; and there seems too much reason to fear that these atrocities have been preceded by many similar outrages." These and the adjacent islands, the Andamans, would, it has been suggested, answer admirably for a convict settlement.

NICOLAI, CHRISTOPH FRIEDRICH, a German author, was the son of a bookseller, and was born at Berlin in March 1733. The intense ardour for learning which characterized his life was early shown. Though engaged so soon as his sixteenth year in the bookselling trade, he made himself a proficient in general literature, and in the Greek, Latin, and English languages. His increasing devotion to letters led him in 1757 to resign his partnership in the family firm; and though he was recalled to business in the following year by the death of his brother, yet the projects that he had planned during his retirement were actively carried out. By this time he had formed, in conjunction with Lessing and Moses Mendelssohn, a literary triumvirate, for the purpose of founding a new school of German criticism. They had begun their scheme in 1757, by publishing the *Bibliothek der Schönen Wissenschaften*. They now continued it in 1759 by giving to the world the first of their famous *Letters on Criticism*. It was with a similar end in view that in 1765 Nicolai became the projector and editor of the influential periodical styled *Allgemeine Deutsche Bibliothek*. The severe and prosaic tone of criticism which characterized this work soon involved him in many disputes with some of the greatest writers in Germany. His facile and ever-active pen was especially employed in writing pamphlets and satirical romances against the philosophy of Kant. Fichte and A. W. Schlegel attacked him in turn. Yet the

Nicobars

Nicolai.

Nicolaitans irascible Nicolai continued to wrangle with his numerous enemies, and at the same time to dabble in all sorts of subjects, till his death in 1811. His *Life* was published by Göckingk in 8vo, Berlin, 1820.

NICOLAITANS, a Gnostic sect of the second century, mentioned by Irenæus, Tertullian, and Clement of Alexandria. They claimed to have been founded by Nicolas, one of the seven deacons enumerated in the sixth chapter of the Acts; and they were believed by the early fathers to be identical with the sect of the same name alluded to in the second chapter of the Apocalypse. But neither of these opinions rests on satisfactory grounds. The peculiar tenets of the Nicolaitans were founded on the principle that the passions ought to be allowed to exhaust and destroy themselves by indulgence. "Subdue the flesh by abusing it" was the favourite motto with which they justified their licentious conduct. (Neander's *Church History*.)

NICOLAS, SIR NICHOLAS HARRIS, a very eminent English antiquary, was the fourth son of John Harris Nicolas of East Looe in Cornwall, whose Breton ancestors had settled there on the revocation of the edict of Nantes. He was born on the 10th March 1799. He entered the navy on the 27th October 1808; and after some years of active service as midshipman under his brother, in which he took part in the capture of several armed vessels and convoys on the coast of Calabria, he was promoted to the rank of lieutenant on the 20th September 1815. Not succeeding at the close of the war in obtaining employment, he left the service, and took to the study of English law and antiquarian literature. His first work, *The Life of Secretary Davison*, appeared in 1823, the author having married a descendant of the family of that worthy privy counsellor during the previous year. He was called to the bar by the society of the Inner Temple in 1825, but his practice never extended beyond the occasional claims of peerage before the House of Lords. Nicolas was chosen shortly afterwards a Fellow of the Society of Antiquaries, became a member of their council in 1826, and was a frequent and valuable contributor to the *Archæologia*. His imprudent zeal and violent temper, however, did not permit him long to enjoy this dignity; for after his first appearance at its deliberations, the society struck him off their list. He thereupon commenced a series of attacks against the administration of the affairs of the society, which do not seem to have been in the most perfect state possible. These animadversions, besides appearing in pamphlets, found a frequent place in the pages of the *Retrospective Review*, of which Nicolas had become joint editor in 1826. He continued with incredible industry to elucidate and illustrate various departments of history, genealogy, and heraldry, in a series of works, displaying great research and sound critical acumen. As a whole, his works possess a substantial historical value; but those perhaps in which he has placed the majority of writers under the greatest obligations to his industry and acuteness, are the *Synopsis of the Peerage of England*, 2 vols., 1825; the *Testamenta Vetusta*, 2 vols., 1826; and his *Chronology of History*, a work of great value, written in 1835 for Lardner's *Cyclopædia*, and remodelled from his *Notitia Historica* of 1824. In his *Controversy between Sir Richard Scrope and Sir Robert Grosvenor*, 2 vols., 1832, a work which was never completed, and in his *Siege of Caerlaverock*, there occur a number of highly valuable biographical notices; and, among others, one of Geoffrey Chaucer, which the author afterwards enlarged for Pickering's Aldine edition of that poet. For the same series of British poetical authors, Nicolas wrote the memoirs of Surrey, Wyatt, Collins, Cowper, Thomson, Burns, and Kirke White. In connection with the same field, he made some curious and successful explorations in his *Lives of Isaak Walton and Charles Cotton*, prefixed to Pickering's beautiful edition of

The Complete Angler. His greatest works, however, and those by which his name will be longest remembered by the majority of readers, are the *History of the Orders of Knighthood of the British Empire*, four large 4to vols., 1841-42; and *The Dispatches and Letters of Admiral Lord Viscount Nelson*, 7 vols. 8vo, 1844-46. In acknowledgment of his merits in connection with the former work, he was made a knight of the Hanoverian Guelphic Order in 1831, was appointed chancellor of the Ionian Order of St Michael and St George in 1832, and was advanced to the grade of Grand Cross by Her Majesty in 1840. Sir Harris left an unfinished *History of the British Navy*, in 2 vols., which promised to be a work of very great merit. He was engaged in editing the papers of Sir Hudson Lowe, until within a few days of his death, which took place at Cape Curé, near Boulogne, August 3, 1848. (See *Gentleman's Magazine* for October 1848, which contains a complete list of his writings; and *Athenæum* for August 12, 1848.)

NICOLAS I., *Pavlovich*, Emperor of Russia, was the third son of the Emperor Paul, and was born at St Petersburg on the 7th of July 1796. He succeeded his eldest brother, Alexander I., on the 1st of December 1825, and was crowned at Moscow on the 3d September 1826. He declared war against the Shah of Persia in this latter year, incorporated the kingdom of Poland with his own empire in 1832, commenced a war with Turkey in 1853, which brought against him the allied armies of England and France in 1854, and died on the 2d March 1855, leaving his throne to his eldest son, the present Emperor Alexander II. (See RUSSIA.)

NICOLAS, or NICHOLAS, St, a town of Belgium, in the province of East Flanders, is the principal place in the populous and well-cultivated district called the Pays de Waës, 20 miles N.E. of Ghent. It is well built, with broad and regular streets, and a spacious market-place, surrounded with fine houses. There are several churches, one of which, that of St Nicholas, is a handsome structure; a town-hall, a college, several schools, an hospital, two orphan asylums, and a prison. Among the manufactories of the town, tanneries, breweries, distilleries, salt-refineries, dye-works, and potteries are the chief; and in addition to these, linen, cotton, woollen, and silken stuffs, carpets, lace, hats, tobacco, chocolate, earthenware, &c., are manufactured. In corn, flax, hemp, linen, &c., an active trade is carried on; and a market for flax is held here which is said to be the largest in the world. Pop. 20,500.

NICOLAUS, surnamed *Myrepsus*, or "the ointment-maker," the author of a Greek pharmaceutical work, flourished in the thirteenth century at the court of the Emperor John III. His treatise is known to the public only in the form of a Latin translation entitled *De Compositione Medicamentorum*. Its value is almost cancelled by the fact that it places the most absurd monkish charms and talismans in the category of remedies, and is little else than a compilation from Nicolaus Præpositus, and other medical writers. Yet it has found a place in the second volume of H. Stephens's *Medicæ Artis Principes*, fol., Paris, 1667, and has since been reprinted.

NICOLAUS, surnamed Præpositus to distinguish him from Nicolaus Myrepsus, was the author of a Latin pharmaceutical work entitled *Antidotarium*, and flourished in the former half of the twelfth century as the principal of the medical school at Salerno. His book was a standard authority during the dark ages, was first printed at Venice in 1471, and has frequently been republished.

NICOLAUS DAMASCENUS. See DAMASCENUS, *Nicolaus*.

NICOLE, PIERRE, one of the most illustrious of the Port-Royalists, was born at Chartres on the 19th October 1625. His father, Jean Nicole, who was a parliamentary advocate, succeeded early in imbuing the mind of his son with not a little of his own taste for classical literature. At

Nicolaitans
||
Nicolas.

Nicolas
||
Nicole.

Nicole. the age of fourteen this grave and studious boy had completed his preliminary studies; and his father removed him to Paris, where, in 1644, he finished a course of philosophy and theology, and took his master's degree. The university of Paris was at that time in a ferment touching the celebrated propositions of the Jansenists; and Nicole had his attention turned to the solitaries of Port-Royal. The profound piety of that venerable community, and the austere tranquillity of their life, had strong attractions for a spirit so calm and meditative as that of Nicole, whose only wish was for study and retirement. He accordingly betook himself to their quiet retreat, and divided his time during the three following years between studying the theology of the Sorbonne, and giving instructions in *belles lettres* in the educational institutions of Port-Royal. Having made application for licence, it was discovered that his opinions were not in accordance with those of any Roman Catholic university, much less with those of the theological faculty of Paris, and he resolved to content himself with his theological *baccalauréat*, which he had obtained in 1649. From this period he attached himself more closely to Port-Royal and the Jansenists, and soon after took up his pen, in conjunction with the celebrated Antoine Arnauld, in defence of Jansenius and his doctrines. Nicole never adopted Jansenism, however, in all its extreme rigour. In various treatises written at a comparatively early period of his career, he took exception to not a few of the doctrines of his brethren of Port-Royal, even while he put forth all his strength in behalf of what he regarded as their grand claims upon his fellow-men. This attitude is most noticeable perhaps in a theological dissertation, published by him in 1657, under the pseudonym of Paul Irenæus, designed to pacify the Church, and to prove that Jansenism was only an imaginary heresy. This interesting work bore the title of *Disquisitiones sex Pauli Irenæi ad præsentem Ecclesiæ tumultum sedandos opportune*. In 1658 Nicole made a journey into Germany in behalf of the cause; and during his residence there, translated into Latin the famous *Lettres Provinciales*, which had recently issued from the most gifted pen among the Port-Royalists. During the execution of this task, the translator read Terence incessantly, in order to catch the rare pungency and sprightliness of the dramatist, and transmute it, if possible, into his version of these immortal letters. He submitted his work to the Germans and Dutch as the performance of "William Wendrock, doctor of the University of Salzburg." On his return he retired with Arnauld to Châtillon, near Paris, to devote himself with renewed ardour to the prosecution of his cherished pursuits. One of the earliest products of his pen in this retreat was the part he took in the composition of the celebrated "Port-Royal Logic," published anonymously at Paris in 1662, under the title *La Logique, ou l'Art de Penser*; a work of pre-eminent merit, which stands unrivalled even to the present day as an introduction

to the study of the laws of thought.¹ In 1664 Nicole gave to the world his well-known *Perpétuité de la Foi*, better known as *La Petite Perpétuité*, which the attempted refutation of Claude induced the author to expand, five years afterwards, into *La Grande Perpétuité*, in 3 vols. 4to. The reputation gained for the humble Port-Royalist by this striking performance proved too much for his modesty, and he was fain to attribute the merit of it to his illustrious friend Arnauld. *Les Visionnaires* (1665-6), directed by Nicole against the absurd mysticism of the poet and romancist Desmarests, called forth a bitter attack from Racine upon his ancient master at Port-Royal. At the urgent request of his friends, Nicole in 1676 again solicited ordination, but found his Port-Royal sympathies too great a barrier for the liberality of the Bishop of Chartres. A *Lettre* which he wrote in 1677, for the bishops of Saint-Pons and Arras, to Pope Innocent XI., on the laxity of the casuists, raised such a storm against him that he was obliged to withdraw from the capital. On the death (in 1679) of the Duchesse de Longueville, the most ardent protectress of Jansenism, Nicole, considering himself as no longer safe in France, left the kingdom, and sought an asylum in the Low Countries. He returned to France in 1683, and after remaining in concealment for some time, ultimately took up his abode at Paris and resumed his literary occupations. It was during this period that he completed his *Essais de Morale*, of which the first four volumes had been given to the public between 1671 and 1678. The last two volumes were published after the author's death, the fifth in 1700, and the sixth in 1714. After *L'Art de Penser*, it is unquestionably on this work that Nicole's reputation as a philosophical writer mainly rests. We search in it in vain, however, for much decided speculative originality. His strength did not lie there. He is mainly occupied with delineations of a moral and religious nature, characterized by exquisite subtilty and discrimination; but he seldom or never permits his thoughts to traverse the decisive circle meted out by his faith. Yet one constantly admires the delicate observation, steady judgment, and calm spirit of the man. Among his moral treatises there is, perhaps, no one more characteristic of the author, and certainly no one superior to *Les Moyens de Conserver la Paix avec les Hommes*. It is only after reading this that one can adequately estimate how great must have been that loyalty to the cause of truth, and devotion to the honourable brotherhood with whom he laboured, which could have induced so gentle a nature to leave the quiet which he loved so well, to do earnest battle in the arena of religious controversy, or to share in the fierce strifes of political partizanship.² The repose which his nature longed after he was not destined to find here. "Rest! we shall rest through eternity," said the bright and brave Arnauld to him reproachfully. Nicole's closing years were occupied with two notable controversies,—the one on monastic studies, in which he defended the liberal

Nicole.

¹ The authorship of this famous work was for a long time problematical. It was sometimes ascribed to Nicole, sometimes to Arnauld, and sometimes to both. The latter is the correct opinion, however; for the younger Racine, who was a pupil at Port-Royal, informs us, that the dissertations and additions are by Nicole; the first, second, and third parts by Arnauld and Nicole together; and the fourth by Arnauld alone. (See Barbier's *Dictionnaire des Ouvrages Anonymes Pseudonymes*, Paris, 1806.) After the first draft of the book in 1662, numerous changes and additions were made to it in the editions which were issued during the lifetime of the authors. The fifth edition, from which the endless reprints which followed were taken, was published at Paris in 1683. It was translated into Latin soon after its first appearance; and of the various versions of it in that language there have been a great number of editions. A Spanish translation appeared in 1759, and an Italian one some years previously. There have been three English translations of the *Art of Thinking*; the first by "several hands," in 1685; the second by John Ozell, in 1716; and the third by Thomas Spencer Baynes, in 1851. The latter is an admirable performance, and contains an *Introduction*, in which the scientific position, character, and history of the work are carefully traced.

² The simple and ingenuous character of Nicole often manifested itself in extreme timidity and amusing eccentricity. If an objection was raised in a discussion which he had not foreseen, he was entirely disconcerted. "Tréville beats me," he said, "in the chamber; but before he reaches the foot of the stair I confute him." Having resided for a long time in the Faubourg Saint-Marcel, some one asked him why he preferred this locality. "It is," said he, "because the enemies who menace Paris will probably enter by the gate of Saint-Martin, and will accordingly be obliged to traverse the whole city before reaching my place of abode." "When walking in the streets," says the Comtesse de la Rivière, "he was always haunted by the fear that a tile would fall upon his head; and when he travelled by water, he was in perpetual terror lest he should be drowned." (*Lettres de M. L. C. de la Rivière*, Paris, 1776.)

||
Nicolson.

sentiments of Mabilion; the other on Quietism, in which he took part with Bossuet against Fénelon, but with infinitely more honest manliness and liberality than was displayed by the proud "Eagle of Meaux." The weighty labours of a long life and the repeated excitement of controversy, for which his temper was so little fitted, had in 1693 produced their natural effect upon his health. After a lingering illness of two years he was suddenly struck with apoplexy. Crowds of persons from all quarters of Paris hurried to visit the dying couch of the gentle-hearted pious old man. Young Racine, now at the summit of his great fame, forgot his former animosity to the author of *Les Visionnaires*, and, with a restorative medicine in his hand, hastened to where his old master lay. But it was all in vain; the good man's work was done. He died on the 16th November 1695, at the age of seventy. Contrary to his expressed desire to be interred without ceremony, his remains were accompanied to the grave by the most distinguished men of the time.

The works of Nicole, entitled *Essais de Morale et Instructions Théologiques*, form 25 vols. 12mo, and were published between 1671 and 1714. They were reprinted in 1741-44. Among a number of minor performances not already mentioned, there is a *Vie de Nicole* by the Abbé Goujet, forming the 14th vol. of the series. A Life of Nicole will also be found in Besoigne's *Histoire de Port-Royal*, vol. iv.; and another by Saverien, in his *Vies des Philosophes Modernes*, vol. i. The rôle of Nicole at Port-Royal, and his dissent from certain positions of Pascal charged with scepticism, have been placed in a clear light by Victor Cousin in the *Revue des Deux Mondes* for January 1845. On the opposite side, see Flottes' *Etudes sur Pascal*, 1846.

NICOLL, ROBERT, a Scottish poet, was born in the parish of Auchtergaven, in Perthshire, on the 7th of January 1814. His parents were too poor to give him a regular education; but his mother, who was a woman of singular energy and intelligence, snatched an occasional hour when her day of field-labour was done to teach her boy to read. His school education was of the most rudimentary character; but by industry and courage he strove to supply the deficiency. At the age of eight we find him tending cattle for a livelihood, and eagerly reading books. When he was thirteen, he could write an occasional paragraph for a local newspaper; and when bordering on twenty, he had completed his apprenticeship with a grocer and wine-merchant in Perth, and was known as a writer of tales, poems, and songs. In 1834 he opened a small circulating library in Dundee, and during the following year published a volume of *Poems and Lyrics*, which was very favourably received by the press, and soon passed through three editions. His verses, without being characterized by any of the highest qualities of poetry, display great sweetness, purity, and tenderness, and breathe much of the joyous hopeful valour of his life. In 1836 his strongly liberal sentiments got full vent in the pages of the *Leeds Times*, an ultra-radical journal, of which he had become editor. The spirit, energy, and devotion, with which he entered upon this new undertaking, soon tripled the circulation of the paper, but broke the health of the brave young poet. He had been little more than a year in this position when he was compelled to leave it. He died of consumption, at the house of a friend in the neighbourhood of Edinburgh, on the 9th December 1837, at the premature age of twenty-three. (See his Life by Mrs Johnstone, in the third edition of his poems.)

NICOLO, SAN, the chief town of the island of Tinos, in the Ægean Sea, and the see of a bishop, has a modern cathedral, and a population of 4000.

NICOLSON, WILLIAM, Archbishop of Cashell, a learned antiquarian, was the son of a clergyman, and was born at Orton, in Cumberland, in 1655. Having entered Oxford in 1670, he was chosen a fellow of Queen's Col-

lege in 1679, and was shortly afterwards presented to several livings. His favourite studies now began to be prosecuted with vigour. He produced *The English Historical Library* in 1696-99; and *The Scottish Historical Library* in 1702; a series of national antiquarian works, which he afterwards completed in 1724, by the publication of *The Irish Historical Library*. His increasing fame was attended by high ecclesiastical preferment. He was promoted to the bishopric of Carlisle in 1702; was translated to the see of Londonderry in 1718; and had the archbishopric of Cashell conferred upon him in 1726. His death took place a few days after his elevation to this last dignity.

NICOMACHUS, a distinguished Greek artist, the son of the painter Aristodemus, was a native of Thebes, and flourished in the latter half of the fourth century B.C. He rose to be unrivalled both for the celerity and completeness of his execution. If we may believe Plutarch, he closely resembled Homer in the spontaneous, and, at the same time, graceful and vigorous play of his genius; and, according to Cicero, his pictures attained the very pitch of perfection. His success as a teacher was also great. Among his pupils he numbered several who were afterwards famous painters, such as his brother Aristides, his son Aristocles, Philoxenes of Eretria, and Corybas. Yet Vitruvius enumerates him among those artists who were prevented by fortune from rising to their proper place in the public estimation. The following pictures of Nicomachus are mentioned by Pliny:—"The Rape of Proserpine," "Victory riding in a four-horsed Chariot," "Apollo and Diana," "Cybele," "Female Bacchanals," and "Scylla." He was engaged in a magnificent picture of the "Tyndaridæ," when he died.

NICOMEDES I., the earliest of the Bithynian kings who bore that name, succeeded his father Zipoetes in 278 B.C. He inaugurated his reign by the assassination of two of his brothers. This act of jealous cruelty rendered him unpopular. An insurrection, headed by his remaining brother Zipoetes, broke out and established itself in the maritime provinces. Before tranquillity could be restored, he was forced in 277 B.C. to employ the assistance of a horde of Gauls who were then besieging Byzantium, and thus to give that race for the first time a footing in Asia Minor. The rest of the reign of Nicomedes seems to have been spent in peaceful enterprises. In 264 B.C. he founded the great city of Nicomedia to be the capital of his kingdom, and to perpetuate his name. Other beneficial undertakings were progressing under his superintendence, when he died about 250 B.C.

NICOMEDES II., surnamed Epiphanes, assassinated his father Prusias II., and seized upon the throne of Bithynia in 149 B.C. He had spent his youth at Rome as a hostage, had secured the favour of the senate, and was therefore inclined at first to trust for the prosperity of his kingdom to an alliance with the great republic. Not until about 102 B.C., did he attempt to act independently of his powerful allies. Joining himself to Mithridates, the great king of Pontus, he laid hold upon Paphlagonia; and though he pretended to relinquish his conquest at the command of Rome, he set one of his own sons upon the vacant Paphlagonian throne. The next encroachment of the crafty king was not so successful. By marrying Laodice, the widow of Ariarathes VI. of Cappadocia, and by taking her orphan sons under his protection, he thought to gain possession of that kingdom. But the strong hand of Mithridates was by that time upon the coveted crown; the Romans then interfered; and Nicomedes, besides being foiled in his project, was deprived of his former acquisition, the kingdom of Paphlagonia. He died shortly after this of disappointment, about 91 B.C.

NICOMEDES III. was the son of the preceding, and succeeded his father about 91 B.C. His territories lay too

||
Nicomedes.

Nicomedia near the seat of the grasping Mithridates to remain long in tranquillity. In a short time his brother Socrates, instigated by that intriguing foe, rose in rebellion and drove him from his kingdom. No sooner had the unfortunate king, by the intervention of the Roman senate, been re-seated upon his throne in 90 B.C., than he was induced by the crafty counsels of Rome to embroil himself once more with Mithridates. The result was, that in the course of two years his forces were cut to pieces by the troops of Pontus on the banks of the Amnion; his kingdom was invaded; and he did not consider himself safe from his formidable enemy until he had fled as far as Italy. There he waited till the treaty concluded between Sylla and Mithridates in 84 B.C. restored him to his sceptre. The rest of his reign seems to have passed in comparative tranquillity. He died in 74 B.C., leaving no issue, and bequeathing his kingdom to the Romans.

NICOMEDIA. See **ISMIR.**

NICOPOLIS (Turk. *Nikopol*, anc. *Nicopolis ad Istrum*), a town of European Turkey, capital of a pashalic in Bulgaria, stands on the right bank of the Danube, just below its confluence with the Aluta from the N., and the Osma from the S., 80 miles S.W. of Bukharest, and 280 N.W. of Constantinople. It consists of two parts; one of which, inhabited by Mohammedans, and protected by a fortress, stands on a cliff of limestone, several hundred feet high, rising from the river, and surrounded on the other three sides by a ravine. Though provided with heavy pieces of artillery, this castle, being commanded by the surrounding heights, is of very little importance as a defence. The Mussulman town is further defended by ramparts and batteries; and though generally ill built, it presents a fine appearance, with the many glittering minarets of its handsome mosques. On the slopes which rise beyond the ravine, stand groups of white houses, forming the other part of the town, and occupied by Bulgarians, Wallachians, and Jews. The surrounding country is very beautiful, and much of it is laid out in gardens. Owing to its convenient situation on the Danube, Nicopolis is a place of some commercial activity. It was originally founded by Trajan, of whose fortifications some remains still exist; and it is remarkable as the place where the Sultan Bayezid I. defeated Sigismund, King of Hungary, in 1396. It has since that time been repeatedly injured by the Russians. Pop. about 10,000.

NICOPOLIS, "The City of Victory," a town of ancient Greece, stood on the promontory of Epirus, on the low isthmus which separates the Ionian Sea from the Ambracius Sinus (*Gulf of Arta*). It was erected by Augustus in 31 B.C. to perpetuate the fame of the victory which he had gained at the neighbouring headland of Actium. Special care was taken to render it worthy of its imperial founder. A large population was drawn within its walls from the adjacent cities; it was admitted into the Amphictyonic Council; the privileges of a Roman colony were conferred upon it; and it became the scene of a quinquennial festival, called *Actia*, in honour of the above-mentioned battle. Under the successors of Augustus, Nicopolis continued to be the capital of Epirus. It was, however, gradually sinking into decay; and during the dark ages its dilapidated buildings were finally abandoned. About three miles north of the modern town of Prevesa, a line of ruins, stretching across the isthmus, and containing the remains of a larger and a smaller theatre, a palace, a stadium, and an aqueduct, still indicates the site of the ancient city of Nicopolis.

NICOSIA, a town of Sicily, in the province of Catania, occupies two hills near the rivers Salato and Capizzi, 35 miles W.N.W. of Catania. It has several churches and convents. Few or no manufactures are carried on here; but the inhabitants gain their livelihood by agriculture,

and by trading in its produce and in cattle. In the vicinity alum, iron-pyrites, and rock-salt are found; and there are some bituminous and sulphureous springs. Pop. about 13,000.

NICOSIA, or *Lefkosia*, the capital of Cyprus, stands near the centre of the island, on the right bank of the Pedia, in a plain inclosed by mountains. Though somewhat decayed from its former splendour, it still has a fine appearance when viewed from a distance; but the streets are narrow and dirty, lined by houses of which many are in a ruinous condition. It is surrounded by walls and bastions, which have a circuit of about 3 miles; but before these were erected by the Venetians, the town was of much greater extent. A handsome Gothic edifice, formerly the church of St Sophia, is now converted into a mosque, and many of its monuments have been injured by the hands of the Turks. Besides the churches, convents, and mosques, Nicosia has an ancient palace over the entrance of which the lion of Venice still stands; a handsome bazaar; and a khan or inn for the accommodation of travellers. Carpets, cotton stuffs, and leather, are manufactured here; and the principal articles of commerce consist of wine and raw cotton. Nicosia is the seat of a Greek archbishop, and of the Turkish governor of Cyprus. It was formerly the residence of the Cyprian kings of the Lusignan dynasty; and in 1570 was stormed by the Turks, who on that occasion put to the sword about 20,000 of the inhabitants. Pop. about 16,000.

NIEBUHR, **BARTHOLD GEORGE**, the illustrious historian of ancient Rome, was born at Copenhagen the 27th August 1776. He was son of the oriental traveller, Carsten Niebuhr. His family for many generations had been settled in Hadel, the north-western province of Hanover, where they occupied a small patrimonial estate. The elder Niebuhr had been employed by the Danish government on an exploring expedition in Arabia, in the year 1760, in which he exhibited remarkable abilities and energy. On his return, after suffering great hardships, he received an appointment in Copenhagen, married, and had two children,—a daughter named Christiana, and a son, Barthold George, a few years her junior. The mother was also a German by birth; so that Barthold, though born in Denmark, was himself German on both sides, and learnt the German as well as the Danish language in his nursery. When he was two years old his father removed to Meldorf, the capital of South Denmark, a district of Holstein, lying on the shore of the German Ocean, between the mouths of the Elbe and Eyder, which, though subject to Denmark, was occupied by a population claiming closer connection by origin and language with its German than its Danish neighbours. The inhabitants of this border-land had secured in the middle ages a certain political independence, of which they still retained the traces in their habits, their feelings, and their municipal institutions. From these institutions, in which the distinction of classes was strongly marked, Niebuhr drew many illustrations of his theory regarding the relations between the patricians and plebeians of ancient Rome.

The bent of Niebuhr's genius, and his habits of mind, may be traced more clearly than in most cases to the circumstances of his early years. From his father he derived his interest in languages, in geography, and in the manners and institutions of different nations, together with unwearied diligence and great earnestness of character. To his mother he owed apparently his moral and physical susceptibility; he was easily affected by change of climate and temperature, and liable to fits of peevishness and irritability; while at the same time he was endowed with great warmth of heart, and gained the devoted affection of his friends and family. From his father's employment as a fiscal agent in Denmark he acquired his turn for the subject of finance. Accustomed from his infancy to the marshes and moors of his

Nicosia
||
Niebuhr.

Niebuhr. province, it was not till late in life that he acquired a taste for picturesque scenery; to the last the fens of Holland and the plains of the Campagna had more interest for him than the romantic glories of the Alps and Apennines. Meldorf seems to have afforded him no companion of his own age, and but little society among his elders, which could assist in expanding his intellect; but Boje, the prefect of the district, an intimate friend of his father's, was a man of cultivated mind and literary taste; and young Niebuhr delighted in listening to their conversation, and, as he grew up, in devouring the contents of their libraries. Marvellous stories are told of the quickness of his observation, and his powers of memory. His first political interest was excited by the war between Russia and Turkey in 1787, the course of which he followed, or, if his father may be believed, anticipated, with the map before him; and the information he displayed in matters of history, geography, and statistics, was from the first extraordinary. In 1790, his thirteenth year, he was placed at the gymnasium of Meldorf; in 1792 he was removed to a commercial school at Hamburg, and in 1794 was admitted into the university of Kiel. The system of education at a small German university such as Kiel, was very similar to that, little noticed and soon to be forgotten, pursued in our East India College at Haileybury. The students, about 100 in number, lived in habits of easy intercourse, and often of affectionate friendship, with the professors and authorities, frequenting their little parties, and associating with their wives and daughters. The course of study, ranging over two years, was wide, but necessarily superficial, exercising the memory more than the understanding; the students attending, with considerable latitude of choice, the lectures of teachers in the learned languages, in German and Danish history, in jurisprudence, logic, metaphysics, natural philosophy, chemistry, "æsthetics," and philology, and probably others, delivered orally and taken down in writing; great stores of which manuscripts, more or less methodically arranged, they carried away with them to form the basis of future works or lectures of their own. On all these subjects Niebuhr gained crude masses of information which none but a mind of extraordinary activity, such as his own, could have digested. But a more important acquisition than all this learning, for the future development of his character, was the friendship of Madame Hensler, the widowed daughter of one of the professors, a woman of remarkable sense and intelligence, towards whom, being six years her junior, he continued through life to entertain the most respectful regard, with whom he corresponded, without reserve, on all his thoughts and feelings, and whose younger sister he afterwards married. Here he also formed many valuable intimacies; *e.g.*, with the two Counts Stolberg, with Count Adam Moltke, with Voss, Jacobi, Reventlow, and Schlosser.

At Easter 1796 Niebuhr left Kiel. The reputation of his abilities had become known to Count Schimmelmann, the Danish minister of finance, who offered him the place of private secretary. The elder Niebuhr, it seems, had looked forward to his son following his own steps as a geographer and explorer; but he felt that the delicacy of his health was an obstacle to the realization of this plan, and he now advised him to accept this opening to official life at home. Niebuhr accordingly went to Copenhagen, and entered his new patron's service; but in August the same year he was appointed secretary to the royal library by the prime minister Bernstorff, the duties of which post he combined, at least for a time, with those of the other. Almost at the same time he received the offer of some literary post in France; and again Schimmelmann proposed to him the situation of consul-general at Paris. Both these offers he declined. "How could I bear," he said, "to live so far from all who are dear to me, among a na-

tion to whom in general I have an aversion?" Such was the variety of openings, not lucrative perhaps, but involving some responsibility, which presented themselves to a young German of twenty years of age, known for his abilities only in the small circle of one of the least conspicuous of German universities.

In August 1797 Niebuhr went to see his friends in Holstein. On this occasion the regard he had long entertained for Amelia Behrens, the younger sister of Madame Hensler, determined him to make her the offer of his hand; and the young couple, Niebuhr being at this time twenty-one, and the lady three years older, became solemnly betrothed. He returned to his duties at Copenhagen; but his views now pointed to a professorship at Kiel, which might enable him to marry, and devote his life to literary labours. Before, however, entering deliberately on the career to which he had destined himself, Niebuhr was anxious for the improvement to be derived from foreign travel, and particularly for an opportunity of making himself acquainted with England, a country to which his father was much attached, and in which he had himself felt especial interest from a child. In June 1798 he sailed from Cuxhaven, landed at Yarmouth, and went direct to London, where he resided till October, and then fixed himself for six months at Edinburgh. Here he attended the university for one session, and after travelling through parts of Scotland and England, returned home in November 1799. His letters from this country show with what active interest he studied the character and customs of the English; but it is to be regretted that the acquaintance he formed here was confined to a few families and individuals within a narrow circle; and the habit of hasty generalization, to which he was through life addicted, was never more conspicuous than in the conclusions he drew from his limited experience regarding the whole subject of English life and manners.

In the spring of 1800, Niebuhr having obtained two small appointments from the government at Copenhagen, took up his residence there, and married his betrothed. It is from this time that his thoughts and reading began to be directed particularly towards classical antiquity, gradually centring in the history of ancient Rome. Six years passed in intense study and moderate employment, until, in 1806, his name, not only as a scholar, but as a man of business and knowledge of commerce and finance, rising higher and higher, he received an invitation to transfer himself to the service of the Prussian government. In accepting this offer, after mature deliberation, he acknowledges himself to have been influenced in some degree by pique at an anticipated slight in his official career in Denmark. His temper was undoubtedly irritable, and his extraordinary quickness of apprehension was combined apparently with some restlessness; but the charges sometimes made against him, of ingratitude to his first patrons, and insensibility to the claims of his country, are wholly unreasonable. Schimmelmann and Bernstorff seem to have given their full consent and approval to his proposed migration; and Niebuhr, as we have seen, was himself a German, not a Dane, by origin. At that moment, in the attitude of resistance to France assumed generally by the nations of Eastern Europe, a feeling of common nationality pervaded all the people, at least of Teutonic birth and language. At a later period, indeed, when the independence of the whole of Germany seemed hopelessly lost, Niebuhr could contemplate without hesitation the prospect of seeking a retreat for his literary labours in Russia.

The change of life, however, which he now made was, at its commencement, far from auspicious. He had enrolled himself a citizen of Prussia at a moment when the very existence of the Prussian state was trembling in the balance. He arrived at Berlin, October 5, 1806, only nine days before the fatal battle of Jena, which, with the disas-

Niebuhr. ters which rapidly followed, obliged him quickly to quit the capital, and seek more and more distant retreats in the train of the flying government. He thus passed through Dantzic and Königsberg; and at last, about the beginning of 1807, found himself at Memel, the northern extremity of the kingdom. He had been placed in the department of finance, for which he was qualified by previous connection with the bank at Copenhagen. The minister who had discovered his merit, and secured his services for Prussia, was Von Stein, who seems to have had the highest confidence in his abilities as a financier. But the overthrow of Prussia in the war with France brought about a complete change of administration. Stein was replaced by Hardenberg; yet, though he lost a personal friend at the head of affairs, Niebuhr's talents seem to have been not less appreciated by the new minister. The financial department of the commissariat was intrusted to him, and he removed to the head-quarters of the government at Tilsit; till, on the utter overthrow of Prussian independence, he desired leave to retire to Copenhagen, and there await the result. He was prevailed upon to remain; and when Napoleon demanded the dismissal of Hardenberg, Niebuhr, in the wreck of the government, was appointed with four others as a provisional commission to carry on affairs till a new administration could be formed. The finances of the country were, of course, in utter confusion; immediate measures were required to provide for paying the interest of the public debt; and some fiscal reforms and arrangements, now set on foot by Niebuhr, were accepted afterwards by Stein, when he succeeded to the head of the government. Niebuhr was now appointed to negotiate a loan at Amsterdam, and thither he repaired with his wife in March 1808. There he remained for a year; but his negotiation was unsuccessful: he paid a visit to Ditmarsh in 1809, and returned to Berlin at the end of the year, where he was once more placed at the head of the department charged with the management of the national debt and the supervision of the banks.

In 1810 Niebuhr found his administrative views so much at variance with those of Hardenberg, who had once more replaced Stein, that he demanded his dismissal, and requested at the same time an appointment as professor at the new university then about to be opened at Berlin. In his conduct in this matter it seems impossible to acquit him of waywardness, and of weakly giving way to his habitual restlessness of disposition. Hardenberg was sincerely anxious to retain his services, willing to discuss and consider his views, and to come to an understanding with him; and Stein himself, the rival of Hardenberg, and Niebuhr's patron and personal friend, judged his conduct indefensible. In a private letter to Humboldt, Stein thus expresses himself,—“Niebuhr declares his dissentient opinion. M. von Hardenberg invites him to discuss the matter with him, and to send another plan: to this he vouchsafes no reply; but instead hands in a lengthy chain of arguments against Hardenberg's plan to the king, without bringing forward any other project; and now he wants to appear as a martyr to the truth. All this is nothing but a refined egotism,” &c.¹ Niebuhr, it would seem, was beginning to pine again for the literary occupation to which he was always recurring in the midst of his official duties. After stating to Madame Hensler, in very general and vague terms, his grounds of dissatisfaction with the government measures, he adds,—“Besides this, I must confess, that my sorrow for the sacrifice of *my inward life* to this *miserable finance* often wakes up with renewed force.” He allows himself to ramble on in a very unworthy strain of reflection. “A consciousness how dearly any perfection in this art must

be purchased by a man who is fit for something better, is probably the true reason why *so few honest men have ever made themselves masters of it*. For a long time past I have been almost unable to refresh myself by study. . . . This *estrangement from my true life* has now lasted nearly three years and a half.” It was evidently high time, to speak in the mildest language, that the man of letters should return to the occupations from which he had been so long dissevered; and we may rejoice, as he did himself, when the king acceded to Hardenberg's recommendation, and gave him the post of historiographer. The minister, however, continued to consult him occasionally on financial matters; and Niebuhr, released from the responsibilities of office, was not unwilling to tender his counsel.

We may ascribe to the natural vanity of a young man, raised to important public offices by the disastrous circumstances of his country,—for the flower of the youth of Prussia was drained off into the army,—the overweening opinion Niebuhr seems to have entertained of his administrative abilities. But none of his admirers—and no man has received more indiscriminate admiration—have ever pointed to any special service he rendered to Prussia in the various situations he filled in the government; and there seems much reason to apprehend that, in relieving himself from his official duties, he yielded to an impracticable temper, ill suited to the conduct of public affairs. However this may be,—and his friends, it should be mentioned, averred that eventually even Stein acknowledged the correctness of his views on the question between him and his superior,—there can be no doubt that the change now made in his career was fortunate for his fame, for his comfort, and for the interests of literature. From this time Niebuhr experienced but little interruption in his devotion to letters, to classical antiquity, and specially to the history of Rome. When the Prussian government was in want of able civil administrators to direct or recruit the finances, it was obliged to seek out a clever youth from a neighbouring country, almost fresh from academic distinctions; but when it had to create a new university in its capital city, and furnish it with a body of professors fitted by their reputation and abilities to place it at once on a level with the oldest and most renowned seats of learning in Germany, it could command the services of a whole corps of men, each of them among the most illustrious in his own department of knowledge. Niebuhr, whose reputation was destined to eclipse them all, was less famous in 1811 in the republic of letters than Schleiermacher, Savigny, Heindorf, Buttmann, and others perhaps of the Berlin professors, among whom he was now to be admitted. In the prostration of Prussia at this period, while Stein at least, and a few others perhaps, were secretly preparing the country to re-assert her independence at the favourable moment, the men of letters seem to have made up their minds to forget their political degradation in their earnest devotion to intellectual speculation. The university of Berlin gave great impulse to thought among the educated men of the country; the professors above enumerated exercised, with many others, great influence on the intellect of the age, and impressed a character for boldness, freedom, and originality upon the literature of Northern Germany. In his capacity of historiographer, Niebuhr devoted himself specially from the first to the history of ancient Rome. In 1811–12 he delivered courses of lectures upon this favourite subject; and these, with the promptness and ardour of his impatient temperament, he worked up without delay into two volumes of a history, which he published before the close of the second of these years. The appearance of the original edition was unfortunately timed. The stirring political events

¹ Steins' *Leben*, ii. 507, quoted in *Niebuhr's Life and Letters*, i. 234.

Niebuhr. of 1813 cast it wholly into the shade. Even the author, in the ardour of his patriotism, was contented to forget it while he himself carried a musket on the exercising ground, and undertook at the same time the conduct of a political journal. With the return of peace and leisure for literature, the history was not found to command all the approbation or attention its author might have expected. Though at a later period, as has been already intimated, he changed his views on many essential points, he was far from acquiescing at the time in the objections urged against them, and continued loudly to proclaim the blindness and stupidity of all who refused to accede to them. It was fortunate, perhaps, that a long interval was now given him for reflection. He had scarcely resumed the quiet tenor of his lectures and studies, after the return of peace, when it was painfully interrupted by the increasing weakness, and finally by the death, of his amiable wife, whose health, always precarious, seems to have suffered much from the hardships of the migratory winter of 1806. Her parting injunctions to him were to continue his history "for her sake;" she had perceived, perhaps, that his task had become already irksome to him, and he wanted encouragement to pursue it. But her loss for the time completely broke his spirits, and he accepted, as a relief, the timely and considerate offer of the Prussian embassy at Rome,—a post which ordinarily was little more than honorary, but which, in the contemplated event of a concordat being arranged with the Pope, would require both tact and ability. Before setting out on this long and distant banishment, at which his sensitive nature was considerably dismayed, Niebuhr was fortunate in securing himself a second wife in the person of Margaret Hebrem, the niece of Amelia, a woman of excellent sense, though probably with less appreciation of his intellectual character than the first, and who, confident of the influence she should gradually win over his affections, was content to stand avowedly second for a time in his imagination.

In July 1816 the newly-married couple quitted Germany. They were accompanied by Brandis, who has since attained a distinguished name in literature, as secretary to the legation. They passed through Wurzburg and Munich, where Niebuhr did not omit to examine the MSS. in the libraries; Innsbruck, where he inquired with intense interest into the circumstances of the recent patriotic struggle of the Tyrolese; and Verona, where he made his discovery of the Institutes of Gaius. This discovery was notified by Niebuhr in a letter to Savigny from Venice, but he at first supposed the fragment to be a portion of Ulpian. He copied on the spot a single leaf, and sent it by way of specimen to his friend at Berlin, where measures were promptly taken for the recovery and publication of the lost treasure. After visiting Venice, Bologna, and Florence, he reached Rome on the 7th October 1816. At the period of his arrival there he seems to have been depressed in spirits and suffering in health; he saw Italy also for the first time under the pressure of famine; and, among other personal inconveniences, the vessel in which his books were sent to Lueghorn was wrecked at Calais, and he remained for several months uncertain of their fate. He complained of the character of the people; he was dissatisfied with, perhaps disappointed at, the meagre remains of antiquity which were alone apparent—at least on a first view—upon the site of the greatest of ancient cities, as well as in the country around; and he was harassed by the difficulty of studying at a place where he could only read in the public libraries on certain days, and for some limited hours. Under these circumstances, peculiarly untoward to a man of his temperament, he seems to have been long unable to work upon the History to which he had hoped to devote himself with more zeal than ever; and though he was never idle, and constantly making some discoveries among the MSS. of the

Vatican, he did not for some time recover the even tenor of his literary habits. Gradually, however, the vexations of his position wore off; he was able to look with more indulgence on the character of the people; he found more to admire and attract him in the scenes around him; the respect in which he was personally held enabled him to relieve himself from the frivolities of the society among which his position might have thrown him; he regarded with genial sympathy the enthusiasm of a clique of young German artists, especially the painter Cornelius, who, in their turn, revered him as a patron and director; and, finally, the birth of a son, in April 1817, came opportunely to brace all his energies, and fill him with pleasant and hopeful views of life. To the child he gave the Roman name of Marcus; and began from the first month of its existence to lay out his plans for its future education and career. He continued all this time in constant correspondence with his literary friends at Berlin, especially with Savigny and Nicolovius; but his letters to Madame Hensler still present, as before, the fullest picture of his life, his thoughts, and his interests. He occupied himself with his usual assiduity, but in desultory studies, tending, however, for the most part, in the direction of Roman history, the reading of the Latin scholiasts, the publication of various fragments he discovered of Livy and Cicero, and the investigation of the history of the successors of Alexander, as a preparation for the period when the Romans first came in contact with the Greeks and Orientals. During the greater part of his residence in Rome he occupied lodgings in an old palace built on a lofty story of the ancient theatre of Marcellus, which lies between the Capitoline and the Tiber.

The negotiations with the papal government, to carry on which Niebuhr was ostensibly sent to Rome, were not brought to an issue till 1821, when he had been at his post more than four years. The favourable termination of the affair followed quickly upon a visit paid to Rome by Hardenberg in person, and the minister's friends claimed for him the merit of settling it. The friends of Niebuhr, on the other hand, maintained that all the preliminaries had been arranged by him, and that the successful issue itself, though Niebuhr himself allowed all the credit of it to fall to his superior, was owing to his zeal and tact. There can be no doubt that Niebuhr had made himself personally respected both by Pius VII. and his minister Cardinal Consalvi; but it appears that he had to wait nearly four years for his instructions from the court of Berlin, and in the negotiations themselves he could have borne little part. At all events it would seem, from the serious quarrels which ensued fifteen years later between the popish Archbishop of Cologne and the Prussian government, that the concordat, whether it were the work of Hardenberg or of Niebuhr, failed to make a practical settlement of the questions it dealt with.

Brandis, the secretary of legation, had removed from Rome before this time. He was succeeded by Bunsen, who became one of the most devoted of Niebuhr's friends and admirers. In 1821 Niebuhr was engaged in sketching the plan of the great work on Roman topography which Bunsen, Platner, and other coadjutors, have since given to the world,—a work ill arranged and unequal in the execution of its parts, but deserving, on the whole, to be considered one of the most important and valuable of modern additions to our knowledge of Roman antiquity. Some of the chapters, particularly that which gives a general history of the site of the city,—the most vivid and interesting of the whole,—were contributed to the work by Niebuhr.

In 1822 Niebuhr had been six years absent from home. The chief object of his mission had been effected, and notwithstanding the increasing estimation in which he was held, and his consequently increased means of usefulness, evinced on some public occasions, he became anxious to

Niebuhr. return to Germany. His family now consisted of one son and three daughters, and he was dismayed at the idea of bringing up children amidst a society for which generally he had so little respect. Having obtained, in the first instance, temporary leave of absence, he allowed himself, apparently for the first time,—such was the insecurity of the country even round Frascati and Tivoli,—to leave the immediate neighbourhood of Rome, and paid a visit to Naples in the spring of 1823. Returning from thence at the end of five weeks, he took his farewell of Rome, and commenced his journey northward in May. At St Gall he passed some weeks, to recruit his health and to examine the MSS. in the library there,—a labour which was repaid by the discovery of the poem of Merobandes, which he prepared for publication during his stay. From St Gall he went to Heidelberg, and then on a visit to Brandis at Bonn, where he proposed to take up his residence until it should be finally decided whether or not he should return to his post at Rome.

At Rome, Niebuhr resumed his history in earnest. Some new light had dawned upon him, and cleared up difficulties that had long, perhaps unacknowledged to himself, thwarted his efforts to make any substantial advance. But while still engaged on his third volume he recurred to the correction, and eventually to the re-casting of the two former, and these occupations were again interrupted by a visit to Berlin. Here he obtained a final release from his duties as ambassador, and was gratified with a pension. He was expected, however, to remain for a time in the capital, and give his aid to a financial commission. In the course of 1824, however, he was allowed to return to Bonn, and to devote himself to studies, directed henceforth, rather than interrupted, by the congenial duty of delivering lectures in the university on ancient history. His first course (1824) was on the history of Greece after the battle of Charonea: this was followed by others on Roman antiquities, in the winter of 1825, repeated in 1827; on ancient history generally, 1826; ancient ethnography and geography in the winter of 1827; the history of Rome under the empire, in 1828 and 1829; and a second course on earlier Roman history, in the summer of 1830.

The appreciation of Niebuhr's services to literature seems to have grown rapidly at this period, and this evidently inspired him with more genuine confidence in himself than, notwithstanding a sanguine, indeed we must say a boastful, habit of talking, he had hitherto really felt. In October 1825 he began to work again regularly on his History, and he commenced a thorough revision of the first volumes, without a pang of regret for the past or misgiving for the future, with the full assurance that the book was about "to gain immensely in value," and "its principles to be fixed immoveably for all ages." "I do not hesitate to say," he writes in April 1827, "that the discovery of no ancient historian could have taught the world so much as my work; and that all that may hereafter come to light from ancient and uncorrupted sources will only tend to confirm or develop the principles I have advanced." When the two volumes appeared in their new form, they were at once received with acclamations by the learned, and Niebuhr undoubtedly had the happiness of feeling that he had given a new impulse to historical study, and created, in fact, an era in literature. Among the compliments he received, none seems to have been more gratifying to him than the zeal and ability with which his work was translated by Messrs Hare and Thirlwall, and the favour with which, under their auspices, it was regarded at the university of Cambridge.

Besides working at his History (which he carried on through a third volume), and the daily occupation of the lecture-room, Niebuhr found time to undertake the superintendence of a great work, no less than the publication of the *Corpus Scriptorum Byzantinorum*, to which he himself contributed an edition of Agathias. His name attracted a

number of able assistants, and he received abundance of important subsidies from foreign countries, as well as from Germany, in the shape of collections, emendations, &c. Of this work he speaks with his usual ardour: "Is it not a great thing that a publisher and a philologist should be able to accomplish in six years from hence at the furthest, a work that was but partially carried out in sixty years, under the auspices and with the munificent aid of Louis XIV.?" But his labours now were as regular and methodical as they were incessant. His residence at Bonn continued with hardly a day's interruption, excepting one journey to Holstein; his mode of life was simple, his hours of study and relaxation systematically allotted, and though always actively alive to the politics of the day, and a regular frequenter of the public news-room, he did not suffer his attention to be diverted to other literary occupations than those above mentioned. He no longer indulged in visions of great works to be carried on simultaneously with his History, nor even to succeed it. He began even to limit his views with regard to the great work of his life, and prescribed the triumph of Octavius as the termination of its career. Yet he was more cheerful at this than at any other period of his life, and seems to have hoped to attain his seventy years, like the generality of people, as he says, about him. He had visions also of a future visit to Rome, "twelve years hence." But all these visions or anticipations were suddenly cut off. In the winter of 1830 he had the misfortune to suffer the loss of his house and some of his books and MSS. by fire. He returned to his work with more elasticity of spirit than might have been expected at his age; nevertheless he was considerably shaken by the anxiety and mortification it occasioned him. The French revolution of July 1830 was a still severer blow. He had long regarded the progress of republican principles with a morbid horror, and his mind was now filled with the worst forebodings. He became more assiduous than ever in his study of public events, and in his visits to the news-room. At last, on the evening of Christmas-day 1830, he caught a chill in walking home from the casino, where he had been more than usually excited and heated in perusing the account of the trial of Charles X.'s ministers. He took to his bed, but inflammation of the lungs set in, and in the course of a week his illness reached a fatal termination. He died on the 2d January 1831; and his wife, who had sickened at his bedside, died also on the 11th. They were buried in the same grave, over which the present King of Prussia, formerly his pupil at Berlin, erected a neat and appropriate monument. Upon it a Roman Caius is represented as taking his Caia by the hand, and the lineaments of the two figures portray, with a certain air of Roman formality and sternness, the features of Barthold George Niebuhr and Margaret Hensler. In the summer of 1831 this monument was not yet in existence; but the eyes of the writer of this notice were attracted to a simpler memorial of the great historian at Bonn, in the brass plate on which his name was inscribed still affixed to the door of the house which was his no longer.

The reputation of Niebuhr as a philologist and historian had reached, as we have seen, a distinguished eminence at the time of his decease, and it still continued to rise. He was admitted, both in Germany and in this country, as a standard authority on the points of classical antiquity to which he had devoted himself, and the revolution he had aimed at effecting in the principles of Roman history were accepted, almost without dispute, as accomplished and ratified. According to the testimony of his admirer the Chevalier Bunsen, he was even more fully appreciated in England than in his own country; and the fact of 7000 copies of the English translation of his History (vols. i. and ii.) having been purchased within eight or ten years from the publication, is adduced in proof of our superior discernment. But

Niebuhr. even in Germany, as Niebuhr himself remarked, with reference to the sale of his *Byzantine Corpus*, a class of wealthy collectors had arisen, the number of which furnished no measure of the number of readers; and any man acquainted with English scholarship knows well that, notwithstanding a certain amount of superficial reading or handling of Niebuhr's volumes, there were but few among us who really made a study of them, or rendered themselves competent to express a reasonable judgment upon them. Still, the great principles of his work, his reputed discoveries, and more particularly the spirit in which they were conducted, sank deeply into the academic mind of England; and his genius, especially after it received the enthusiastic adoration of Arnold, was admitted as almost beyond cavil, or even qualification. In Germany the results of his investigations were more strictly questioned from an early period, and more severely criticised. The time was coming when a great re-action was to set in with regard to Niebuhr's estimation in this country also. There can be little doubt that the publication of his Lectures, and still more of his correspondence (*Lebensnachrichten*, &c., abridged and translated into English, 1852) has tended very sensibly to diminish it. The Lectures, it must be allowed, have been published at a great disadvantage, having been only taken down from his oral delivery in the lecture-room, and bearing evident marks, not only of the occasional haste and incorrectness of all lectures delivered *vive voce*, as these were, without even the assistance of notes, but of inexperienced and unskilful abridgments, and often of actual misconception. Of these Lectures three series have been given to the world by Dr Leonhard Schmitz, himself a hearer of them: they embrace a course on Ancient History generally, which must be pronounced extremely meagre and colourless; and another on Ancient Ethnology and Geography, about one-half of which is devoted specially to Italy and Rome, undoubtedly far more interesting, though abounding, to what must be called a morbid extent, in crude theories and groundless assertions. A third course, that on Roman History, extending as far as the reign of Constantine, gives a connected view of the spirit in which Niebuhr would have treated the later portions of the work before him; it cannot be said, however, that it evinces any of the novelty or originality which so strongly characterize his discussions on the earlier period, nor is it drawn out sufficiently in detail to enable us to judge of his powers of narration and description. On the whole, it must be said that these Lectures have been received with great disappointment by the English reader, and have given a shock to the feeling of unbounded devotion with which the author was previously regarded.

The publication of the *Lebensnachrichten* is perhaps still more to be regretted than that of the lectures. The correspondence of Niebuhr exhibits, no doubt, in glowing colours, his earnestness of character, his strict integrity, his generous sympathy with everything noble, and detestation of all meanness and injustice. Yet all this was patent to a reader of ordinary insight on the face of his published History, and required no further illustration from his life and letters; while the evidence we receive from it of his amiableness as a son, a husband, a parent, and a friend, is in some measure balanced by certain indications of peevishness, changeableness, and other infirmities of temper, which are calculated to provoke and mortify those who were most disposed to admire him. But it is with Niebuhr's literary character that we are most concerned. The correspondence, and various essays and fragments of essays on literary and political subjects, contained in the

Kleine Schriften betray infirmities of judgment which are quite surprising.¹ His views, for instance, on the dates of Petronius and Quintus Curtius, are now generally regarded as founded on very inadequate bases. His theory that the municipal institutions of Italian towns in the middle ages were derived, not from the northern conquerors, but from the Romans, has been rejected by modern inquirers. He was especially proud of his acquaintance with the institutions and politics of England; yet he was wont to illustrate the claims of the Italian allies on the Roman republic by comparing them with the demand of the Irish Catholics for the so-called emancipation, forgetting that from 1793 the Catholics had acquired the franchise, the point for which the Italians contended, and that their later cry was for admission to Parliament, to which the claims of the Italians presented no analogy whatever. His want of practical good sense is shown characteristically in the notion he elsewhere promulgates, that it would have been best for the world that Spain should have retained her American colonies, opening the trade with them to foreign nations through Cadiz as an emporium, evidently with a retrospect to the days of ancient or mediæval commerce. All these views, and many others equally frivolous, are advanced with a dogmatism which is painful in a man of real genius, as in any other it would be ridiculous. Further, we have clearly seen how much he prided himself on his insight into the principles of finance: yet we have observed how, on the first occasion when an opportunity really offered for bringing this insight to a practical test, he broke down completely, and, in fact, fled from his post. Gibbon gives three reasons for the decline of the Roman empire: a distinguished English writer of the present day has rejected them all, and laid it wholly on the restriction of the currency and the want of bank-notes. This is a question which it requires not book-learning but actual knowledge of affairs to solve; and of all others it is the question which we had a right to look to Niebuhr, with his official training, to elucidate. Yet, strange to say, there is not a single passage in his History, his Lectures, his Essays, or his Correspondence, which shows that he had ever considered the financial and monetary system of the Romans at all.

Grave complaints have been made against Niebuhr by the Liberals of modern days, for his alleged desertion of the cause of freedom. A fair consideration of his various writings fully rebuts this ill-natured accusation. That there are indications in the course of his life of some vacillation and indistinctness in his views, is no more than may be said with equal truth of almost all thoughtful men,—men of speculation rather than of action,—whose lot has been cast in periods of change and amidst the trial of political principles. Niebuhr's political creed is ably and satisfactorily drawn up in a communication from the Chevalier Bunsen to the translator of his Correspondence; though we must here again remark the unpractical character which appears on the face of his scheme for developing the parliamentary system of Prussia. Deeply impressed as he was with the hollowness of the election system in modern European constitutions, on a mixed but uniform basis of property and numbers, he would have filled his deliberative assemblies by appointment from town-councils and corporations,—a notion which he probably derived from the conventions of the Roman provinces under the empire.

There is yet another subject on which it is still more painful to speak. The character of Niebuhr's mind is remarkably exemplified by his manner of dealing with religious subjects. His feelings on this point were from the first deep and strong. They survived the rejection which, after the many in-

¹ The third volume of the English "Life and Correspondence" contains a selection from the *Kleine Schriften* or "Lesser Writings," as well as from the *Nach-gelassene* or "Posthumous."

Niebuhr. stances of precipitate judgment on his part already alleged, we may call hasty as well as ill-considered, of the greater part of the positive belief of the Christian world. It was on the birth of his son that the sense of the indeterminateness of his own creed,—of the chasm between his feelings and his opinions,—became suddenly intolerable to him; and he determined, and with his curious simplicity of character bluntly declared his determination, that the child “should believe in the letter of the Old and New Testaments.” . . . “I shall nurture in him,” he adds, “from his infancy a firm faith in all *I have lost or feel uncertain about.*” After such an avowal, it is impossible not to feel great distrust in Niebuhr’s speculations on other subjects, and apprehension lest, in perfect good faith and sincerity, he should fatally mislead us for the satisfaction of a theory or a sentiment.

Let us now turn, in conclusion, to the History, the great work by which our author will continue hereafter to be known, and by which it were much to be wished that he could be known only. Niebuhr, it must be clearly understood, comes before us much less as a destroyer of the early Roman history than as a restorer. Among enlightened students of antiquity the incredibility of the narratives of Livy and Dionysius was already admitted, though the main features of these accounts still retain their hold upon them, from the apparent impossibility of constructing a substantial edifice from the fragments of truth, and a natural reluctance to let the ground lie unoccupied. It was not then the destructive, but the reconstructive part of Niebuhr’s History which gave it its peculiar character, and kindled so warmly the imagination of his most intelligent readers. Arnold, above all men, was grateful to his master for restoring to him the possibility of a belief in the Origenes of Roman history. But a sterner, perhaps a colder criticism, has dispelled these last shadowy visions. Among other writers,—for Niebuhr’s theories have been a fruitful field of controversy, particularly in his own country, ever since their publication,—Schwegler in Germany, and Sir G. Cornewall Lewis among ourselves, have shown, it should seem, the actual baselessness of some of the chief of his reputed discoveries.

The most important of these discoveries, or theories, as we must be content to call them, is undoubtedly that which was received with unhesitating conviction, and rendered so popular, in this country at least, by Mr (now Lord) Macaulay and Dr Arnold, as to have been for many years accepted by all our scholars and students as an ascertained fact; namely, the presumed derivation of the early history of Rome from ancient national ballads. Schwegler, a very competent and trustworthy authority on the present state of the controversy, declares that in Germany this theory has been now generally abandoned. Sir G. Cornewall Lewis has recently analysed and discussed it in a masterly manner; and it may be presumed that it will henceforth retain little favour with those among us who have read the *Essay on the Credibility of the Early Roman History*. The positive evidence on which it pretends to rest is shown to be utterly inconclusive. The passages cited from Cato, Varro, Ennius, Cicero, Horace, and Valerius Maximus, are all absolutely irrelevant. The assumption, that fragments of these supposed ballads may be traced in the narrative of Livy, is wholly gratuitous; the assertion that some of his prose is actually verse, and may be read into Saturnian metre is only an amusing fancy; the attempt to produce any analogous instance of history preserved in national poetry is entirely futile. Such is the conclusion to which, whatever his own early prepossessions may have been, a candid inquirer must be brought by a fair examination of the subject, as it is now presented to him.

But interesting and seductive as this theory proved to the first students of Niebuhr’s History, it was still less

attractive perhaps than his interpretation of the relations of the patricians and plebeians, as representing respectively a dominant and a subject race, coalescing gradually into a single political body. This idea, which Niebuhr has developed with peculiar force, and illustrated by minute and multifarious learning, was not wholly new; nor did he stand alone in his own generation in marking the importance of regarding such national relations. The theory that most historic polities have sprung from the subjection of race to race, and that their career is generally to be explained only by constant reference to this circumstance, has been prolific of very serious consequences in modern times. It is not too much to say, that the revolutionary movements which pervaded so large a portion of western Europe in 1848 were directed in no slight degree by pedantic notions of the influence of race and nationality. Niebuhr in Germany, and Thierry in France, gave birth simultaneously to a school of history in which this theory played a conspicuous part. The French writer acknowledged that he derived the first germ of the idea which he developed in his brilliant romance of the *Conquest of England*, from a few pages in an early chapter of Scott’s novel of *Ivanhoe*. There can be little doubt that Niebuhr was right at bottom in conceiving that the institutions of ancient Rome were really moulded, in a great measure, by the mutual relations of different races, with different habits, feelings, and languages, and also with a different political status, yet combining in one polity; but it cannot be allowed that he was always successful in tracing these differences, nor, indeed, that it is now possible to disentangle the hopeless intricacies of the Roman constitution. Thus, for instance, the distinction he alleged, that *populus* properly means the patricians, as opposed to *plebs*, the plebeians; and his bold assertion that Livy was incorrect in using *populus* for the nation in general,—a theory which was once eagerly embraced as the key to much of the early history,—must now be regarded with distrust. His explanation of the real object of the Agrarian laws, which is founded also on his fundamental distinction between the patricians and plebeians,—the burghers, as he delights to call them with reference to certain mediæval analogies, and the commons,—has been also severely contested; but this view, so clear, so interesting, and so apparently satisfactory, may be considered as tolerably well established at the present day.

It will appear, from these remarks, that even in his History, on which the fame of our author pre-eminently rests, he is convicted by modern inquirers of error in some of his fundamental positions. His work can never again be accepted, with the faith and admiration of Arnold, as the basis of a history of Rome. The notion of reconstructing Roman history, of shelling off the husk of the ancient narrative, and bringing to light a new body of facts, of which Livy and Dionysius were wholly ignorant, will probably be discarded from henceforth; while some writers will always be found to cling pertinaciously to the legends of antiquity, others will plunge more and more deeply into scepticism; and we may expect perhaps rather to see the accounts of the later republic and the empire pulled to pieces, than those of the kings and the decemvirate restored.

It is not without pain that the students of Niebuhr—those who have been mainly led by him to look beneath the surface of history, and examine the principles of human affairs—can consent to abandon so large a part of his conclusions, and modify so far their veneration for their master. But Niebuhr must follow the fate of the great inventors before him. Bossuet was the first to snatch at the clue of a Divine Providence through the history of man; and he created a school of historians which will continue always to have its disciples, however much the specific views and conclusions of their founder may be modified or rejected.

Niebuhr. Voltaire and Montesquieu sought the springs of history in the manners and institutions of society; and they, too, have generated a school of philosophic inquiry which has long survived the reputed discoveries of its originators. Niebuhr himself indeed may be regarded as a pupil of this school, though in the depth of his investigations, the sagacity of his combinations, and the boldness of his inferences, he stands far before it, and deserves himself the reputation of an originator and a founder. It is due to him to lay before the reader, in a few words taken from the introduction to his *Lectures on Ancient Ethnography, &c.*, the view he deliberately took of the province of the historian:—

“All history resolves itself into a knowledge of the circumstances in the midst of which events occur, and of the events themselves. In an abstract point of view, the two are conveniently kept apart, although, concretely, they can never appear separated. A history which does not enter into the development of circumstances at all, and altogether presupposes them to be barren, is scarcely conceivable, unless indeed it were written for contemporaries alone. Nevertheless, the one side or the other predominates according to the predilection of the individual historian. Livy gives scarcely anything but the narration of events; earlier historians are fond of occupying themselves with the description of circumstances; and the more ancient the historian the more striking is the peculiarity. Thucydides, the greatest of all historians, whenever he has an opportunity, as in his description of nations, dwells upon the representation of circumstances. In the earliest times, therefore, ethnography and chorography were always the principal objects of attention; while, subsequently, this tendency decreased more and more, and the narration of events alone was attended to. The two, however, ought not to be separated; for, without a knowledge of the circumstances in the midst of which events take place, the study of history is altogether useless. The mere knowledge of a country, however, is not sufficient. The peculiarities of its inhabitants, products, and the like, must be well known to the student; and without this, history has no life,” &c. Animated with this view of what was required in a true expounder of the events and facts of past times, Niebuhr tried to surround himself, as it were, with glowing pictures of the whole life of the people of whom he wrote. His immense erudition, his extraordinary memory, and his vivid imagination, all played into one another; and he believed himself, as he has somewhere said, capable of reproducing before his mind's eye the minutest details of Roman manners and usages. If he dignified with the name of “divination” the habit in which he freely indulged of guessing where it was impossible to ascertain, great allowance must undoubtedly be made for one whose mind had fed from his youth upwards upon the remains of Roman antiquity, and whose fancy had never ceased for a moment to remark, arrange, and combine their scattered fragments, till they assumed at will every shape it suggested. It is his power of imagination which stamps Niebuhr as a man of the highest genius, and will secure immortality to his name and works. Even the errors of such a man will retain a halo of glory in the eyes of posterity; his methods and principles will continue to command respect and imitation; he will be ranked in a triumvirate of philology with Scaliger and Bentley, to whom he bears no common resemblance in his rapid intuitions and bold combinations—in his sanguine temper and unabashed self-confidence—in his aims, his achievements, and his failures.

The following is a list of Niebuhr's works:—1. Published or prepared for publication by himself:—*History of Rome*, 1st edition, 2 vols., 1812; 2d edition of vol. i., 1827; 3d edition of vol. i., 1828; 2d edition of vol. ii., 1830; 1st edition of vol. iii., 1832; edition of Agathias, 1828, and Merobaudes, 2d edition, 1836, for the *Corpus Hist. Byzant.*; *Kleine Schriften*, 1828. 2. Published since his death, in English and German:—*Lectures in Roman History*, by Dr Schmitz, 2 vols.; second edition of the same, with additions, in 3

vols.; *Lectures on Ancient Ethnography and Geography*, 2 vols.; *Lectures in Ancient History*, 3 vols. 3. To these may be added the *Lebensnachrichten*, a biography of Niebuhr connecting the remains of his correspondence, 3 vols., 1838, with a supplemental volume, containing the *Circular-Briefe*,—a series of letters intended for circulation among his family, written during his residence in Holland in 1808–1809; together with a collection of literary and political tracts from his contributions to periodicals. The first edition of the *History*, 2 vols., was translated into English by Mr Walter; the revised *History*, vols. i. and ii., by Messrs Hare and Thirlwall; the 3d vol. by Drs Smith and Schmitz. An abridged translation of the *Lebensnachrichten* has been given by Miss Winkworth, in 3 vols. (C. M.—E.)

Niebuhr
||
Niemcewicz.

NIEBUHR, *Carsten*, a celebrated traveller, and the father of the great Niebuhr, was the son of a farmer, and was born in the duchy of Lauenburg in 1733. His parents died when he was very young, and left him in the condition of a poor peasant boy. Yet at the age of twenty-one he had raised himself to the position of land-surveyor of his native district, and was busily engaged in studying geometry. The vigorous start which he had thus made in life soon carried him on to higher preferments. While he was deeply immersed in 1758 in the study of mathematics at the university of Göttingen, the Count Bernstorff, the minister of Frederick V. of Denmark, began to carry out a project which had been suggested by Michaelis of sending a staff of scientific men to explore the countries of the East. The place of mathematician was offered to Niebuhr. He accepted the office, but his modesty would not permit him to accept the title of professor, which was intended to add dignity to the office. It was in January 1761 that Niebuhr, in company with Von Haven the orientalist, Cramer the physician, Forskäl the naturalist, and Baurenfeind the painter, set sail from Copenhagen. After exploring the gigantic architectural remains of Lower Egypt, the expedition sailed down the Red Sea, touching at various places on the coast of Arabia, and finally landed and established their head-quarters at Mocha. The rest of the journey was saddened by a series of fatal disasters. All the explorers, with the exception of the judicious Niebuhr, had been persisting in living on European diet, and were now sick unto death. Accordingly, when the expedition set sail for Bombay in 1763, Von Haven and Forskäl were left behind in foreign graves; Baurenfeind was buried at sea; and Cramer died at the end of the voyage, leaving Niebuhr to betake himself homeward alone. He lost no time in re-embarking; and after passing through Persia, Syria, and Asia Minor, and marking these countries with an attentive eye, he arrived at Copenhagen in November 1767. It now became his chief business to lay the results of his travels before the world. He therefore published a *Description of Arabia*, in 4to, Copenhagen, 1772; and *Travels in Arabia and the Circumjacent Countries*, in 2 vols., 4to, Copenhagen, 1774–78. These works were remarkable for their new and correct information, expressed in a plain unaffected style; and they soon brought the author into general recognition. The government at Meldorf in Holstein, made him their land-surveyor in 1778; many learned men throughout Europe began to seek his acquaintance; and the Danish government conferred upon him the cross of Danebrog, and the title of councillor of state, and continued to cherish him till the close of his life. He died in April 1815.

Carsten Niebuhr wrote for a German periodical accounts of *The Interior of Africa*, and *The Political and Military State of the Turkish Empire*, and several other papers. His principal works have been translated from the German into French and Dutch. A Life of him by his eminent son was published at Kiel in 8vo, 1817.

NIEMCEWICZ, JULIAN URSIN, a famous Polish poet and patriot, was born in 1757 at Skoki in Lithuania. His youth was spent in learning the profession of a soldier; and at the age of twenty he entered the Lithuanian army. In

Niemen. his own corps he found Kosciuszko, and imbibed from that noble spirit those patriotic sentiments which gave a direction to the whole of his subsequent career. As early as 1788 his energies and talents had begun to be consecrated to the cause of national freedom. In that same year, as one of the deputies for Livonia, he became one of the great patriotic orators of the Polish diet; in 1791, in conjunction with Weyssenhoff, he started the *National and Foreign Gazette*, to be a vehicle for spreading his opinions; and all the while he was fostering the spirit of nationality among the populace by the poems he published and the dramas he produced on the stage. Nor did his activity slacken at the approach of commotion and peril. In the insurrection that followed the second partition of Poland, he was a most efficient confederate of Kosciuszko, both in the council and in the field. But in October 1794 the disastrous battle of Maciejowice was fought; the cause of the patriots received its death-blow; and among the captives who were carried away and immured in the fortress of St Petersburg, was the zealous Niemcewicz. A check was now put for a time upon his national ardour. For two years he lay in his damp cell, relieving the tedium of his confinement by reading the English poets of the eighteenth century, and by translating Pope's *Rape of the Lock*. On his liberation, there was no resource for him but to repair, with his compatriot Kosciuszko, to the United States of America. There he formed new acquaintances, married a lady of New York, and became domesticated. Yet the welfare of his fatherland still lay next his heart; and the intelligence, in 1806, that Napoleon had espoused the cause of Polish liberty, hurried him back to Europe. He was soon appointed, under the newly-instituted grand-duchy of Warsaw, secretary of the senate, member of the supreme council of public education, and inspector of schools; and in these capacities he began a new career of patriotism. His activity did not flag when the Russians had regained their supremacy over Poland. Though reinstalled by the Emperor Alexander in the high office of perpetual secretary of the senate, he did not hesitate to keep alive, both with tongue and pen, the nationality of the people. In 1816 he revived the memory of the ancient glory of his country by the publication of his *Historical Ballads*; in 1817 he pronounced a funeral oration over Kosciuszko; and in 1822 he began to celebrate the great national heroes in his *Collection of Memoirs on Ancient Poland*. All his efforts were evidently aiming at another revolution. Accordingly, the insurrection that broke out in November 1830 numbered the veteran Niemcewicz among its promoters. He was destined, however, to see the favourite project of his life thwarted once more. The remaining strength of his old age was spent in advancing the cause of his beloved Poland in foreign lands. He died at Montmorency, near Paris, in May 1841.

Besides the works already mentioned, Niemcewicz wrote several tragedies and comedies, novels, historical sketches, and translations from the English poets of the eighteenth century. A complete collection of his poetical works appeared in 12 vols., Leipsic, 1838-40. An autobiographical fragment, written in French, and entitled, *Captivity in St Petersburg in 1794-96*, was published in 1843 by the Polish Historical Committee at Paris, and was shortly afterwards translated into English by Laski. (*English Cyclopædia of Biography*.)

NIEMEN, or **MEMEL**, a river of Europe, rises in the swampy regions of the Russian government of Minsk, where it is formed by several small streams between N. Lat. 53. and 54., E. Long. 27. It flows first N., and then W., separating the governments of Vilna and Grodno; then, after making a detour through the latter, it divides them both from Poland, and finally flows through Prussia to the Curische Haff, into which it falls by two mouths. It re-

ceives from the right the Beresina, the Vilia, the Joura, and other affluents; from the left, the Zelva, Szeschuppe, &c. Its whole length is 450 miles; and, though in some places impeded by shoals, a great part of it is navigable. It is of considerable commercial importance; for most of the produce of Lithuania is conveyed by barges down this river; and all the timber exported from Memel is floated down the same channel.

NIEMES, a town of Bohemia, in the circle of Bunzlau, 18 miles N.N.W. of Jung Bunzlau, and 42 N.N.E. of Prague. It contains a fine castle with extensive gardens, a church, town-hall, and school. Linen and woollen stuffs are manufactured here. Pop. (1846) 4181.

NIENBURG, a town of Hanover, capital of the county of Hoya, stands on the right bank of the Weser, which is here crossed by a stone bridge, 29 miles N.W. of Hanover, and about as far S.E. of Bremen. It was formerly fortified, but the defences were destroyed by the French in 1807. There are two churches, a high school, an hospital, several courts of law; linen, cloth, and vinegar manufactures, and some trade in corn and timber. The town has also some river shipping. Pop. (1852) 5052.

NIEUWENTYT, **BERNARD**, an erudite Dutch philosopher, was born at Wastgraafdyk, in North Holland, on the 10th of August 1654. His father, who was a Protestant clergyman, originally designed him for his own profession; but as Bernard displayed a stronger predilection for science than for the church, he was allowed to follow his own inclinations. He studied mathematics, medicine, law, and philosophy with zeal and success. His confidence in mathematical science, however, seems to have been greater than his skill; for in 1694 he commenced a series of attacks upon the calculus, which increased his notoriety, but did not add to his fame. His first brochure was entitled, *Considerationes circa Analyseos ad Quantitates Infinitè Parvas Applicatæ*, &c., Amst. 1694; a work which he followed up next year by *Analysis Infinitorum seu Curvilinearum Proprietates ex Polygonorum Naturâ Deductæ*. Leibnitz replied to his objections in the *Leipzig Transactions*, to which Nieuwentyt produced a rejoinder in 1696. John Bernoulli defended Leibnitz; and Jacob Herman, in a work published at Bâle in 1700, ultimately silenced the Dutchman, to the satisfaction of all intelligent mathematicians. With the exception of *A Treatise upon a New Use of the Tables of Sines and Tangents*, contributed to the *Literary Journal* of the Hague in 1714, we hear no more of Nieuwentyt and mathematics. In philosophy he was a follower of Descartes, and produced some fresh speculations on the subject of natural theology. He attempted to establish the existence of Deity by proofs drawn from the order of nature and from the marks of design exhibited in the universe. His great work on this subject, and the one which forms the mainstay of his reputation, appeared originally in the *Leipzig Transactions*, and was afterwards published in Dutch, under the title of *Regt gebruik der weereld. beschovinge*, 4to, Amsterdam, 1716. In the author's own country it went through four editions in as many years. It was translated into English in 1718; into French in 1725; and subsequently into German by two different hands. The English version was executed by John Chamberlayne, under the title of *The Religious Philosopher*, 3 vols. 8vo, London, 1718-19, and 1730. A new interest attaches to this popular work of the solid Dutchman, from the fact only recently made public (see *Athenæum* for 1848, pp. 803, 907, 930), that Paley's well-known *Natural Theology* seems to have been all but copied from it. Not only has the English archdeacon, it is alleged, borrowed the general argument of the Dutch thinker, he has likewise followed his arrangement, appropriated his thoughts, made use of his form, and copied his details, and that without anything like honourable acknowledgment.

Niemes
||
Nieuwentyt.

Nieuwland
||
Nièvre.

Paley refers twice in his work to the name of Dr Nieuwentyt, but in such a manner as obviously to decline the general admission of the sources of his information. Paley's celebrated *watch* which he found "in crossing a heath" in 1802, had been picked up "in the middle of a sandy down" in Holland, just eighty-six years before. An attempt to extenuate the guilt of the reverend culprit may be seen in the *Athenæum* already referred to. In addition to his other works, Nieuwentyt left a refutation of Spinoza in Dutch, which was published at Amsterdam in 1720. He had considerable fame in his day as a physician; and his good sense, ready eloquence, and amiable character, won him esteem as burgo-master of the town of Purmerend, and gave him great influence in the provincial states. He died on the 30th of May 1718.

NIUWLAND, PETER, a Dutch writer, remarkable for the precocity and versatility of his talents, was the son of a village carpenter, and was born at Diemermeer, near Amsterdam, in 1764. Under the humble tuition of his parents, his infant mind took to learning with an instinctive ardour, and he could compose verses and solve geometrical problems before the age of eight. This ardent predilection for two branches of study so dissimilar, continued to be the prominent feature in his opening intellectual character. At the university of Leyden, to which he had been sent through the liberal patronage of Bernard Bosch, he was equally noted for the easy rapidity with which he solved the most intricate problems of the calculus, and the spirited elegance with which he translated the poetry of the classics. When his academical education had been finished, he appeared before the public in 1787 as the author of a treatise on the means of ascertaining the latitude at sea, and in 1788 as the author of a volume of occasional poems. It was not until he had been appointed professor of navigation and natural philosophy at Amsterdam in 1789 that his attention was exclusively devoted to mathematical studies. He published, in 1793, a treatise on the art of navigation, and two papers in Bode's *Astronomical Almanac*. Other subjects of a kindred nature were engaging his mind; and he was acquiring great academical fame at Leyden in the chair of physics, mathematics, and astronomy, to which he had been promoted in 1793, when he was cut off at the age of thirty. Among Nieuwland's poems is an elegy, entitled *Orion*, which became very popular in Holland.

NIÈVRE, a department of France, lying between N. Lat. 46. 40. and 47. 35., E. Long. 2. 50. and 4. 10; and bounded on the N. by the departments Loiret and Yonne, E. by those of Côte-d'Or and Saône-et-Loire, S. by Saône-et-Loire and Allier, and W. by Cher. Its form is that of an irregular quadrangle; its greatest length is 79 miles, its greatest breadth 65 miles; area 2642 square miles. A range of mountains, forming an offset of those of Côte-d'Or, traverses the department from S.E. to N.W., and separates the tributaries of the Seine from those of the Loire. These hills gradually diminish in height towards the N.W. from 2640 feet to 400 or 600 feet high, and are connected with the Côte-d'Or Mountains by the Mountains of Morvan, which extend westwards in the department of Côte-d'Or, and then southwards between Nièvre and Saône-et-Loire. The general height of this chain is 1600 feet; but one of the peaks, called Mount Prenelay, rises to the height of 2904 feet. The main ridge of the mountains of Nièvre sends off numerous smaller branches, which give the country a rugged and uneven aspect. They are all thickly covered with wood, and present a very wild appearance. The geological structure of the south-eastern part of the department is chiefly granitic and schistose, while in the N. the secondary strata are predominant. There are few extensive plains, except at the north-western extremity of the mountains, and on the borders of the Loire and Allier, where there are some tracts of sandy but fertile soil. The Loire enters the

Nigdeh.

department from the S., crosses it towards the N.W., and then flows northward between Nièvre and Cher. Its principal affluents in this department are—the Aron, the Nièvre, and the Nohain, from the right, and the Allier from the left, which merely skirts the department, separating it from those of Allier and Cher. The Yonne rises in the Morvan Mountains, and flows northwards to the Seine, receiving several small affluents. The streams in the basin of the Loire form numerous ponds, most of which are dried up in the summer; and many canals have been constructed by the inhabitants, which are useful for the irrigation of the soil, and for supplying water-power to various manufactures. The soil is in general poor, but it produces enough of grain for the wants of the people. The climate is temperate but moist; and in some parts fevers are common; from which the valleys of the Loire and Allier are protected by the warm and dry winds which blow from the S. and E. Agriculture has in recent years made great progress in the department; rye and flax are the most important of the crops; and vines are grown with success on the banks of the Loire and Yonne. Of the whole extent of the country, about 303,000 acres consist of arable land, 79,000 of pasture land, 15,000 of vineyards, 368,000 of wood, 27,000 of waste land, &c. The timber of the forests contributes in no small degree to the wealth of the department; it consists principally of oak, beech, and maple. The mineral resources of Nièvre are great, and are worked to a considerable extent: iron, copper, and argentiferous lead are the principal metals; and coal, marble, granite, sandstone, flint, &c., are found in great abundance. One of the principal branches of industry in the department consists in the working of the mines and in the smelting of iron; the annual value of the mineral productions is estimated at L.400,000. It has also been calculated that Nièvre contains 126,000 head of large cattle, 285,000 sheep, 48,000 pigs, 4000 goats, 16,000 horses, 1400 mules, and 2500 asses. There is abundance of game in the department. Besides the smelting of iron, for which there are 30 large furnaces, the manufactures of Nièvre consist of linen and woollen stuffs, pottery, porcelain, hardware, and cutlery of an inferior kind. Some trade is carried on in agricultural produce and in articles of manufacture, especially timber, charcoal, mill-stones, iron, steel, copper, tin, cattle, hides, &c. The internal communication in the country is facilitated by two canals, one of which connects the Loire and the Yonne, and has a length of 86 miles in this department; and the other extends alongside of the Loire for 30 miles in Nièvre. The department forms the bishopric of Nevers; it contains 4 courts of the first instance, and 2 courts of commerce; 4 academies, 2 higher communal schools, and 330 elementary schools. The capital is Nevers; and it is divided into 4 arrondissements, as follows:—

	Cantons.	Communes.	Pop. (1856.)
Nevers	8	99	111,612
Château-Chinon	5	59	67,225
Clamecy	6	93	72,977
Cosne	6	65	74,272
Total	25	316	326,086

Nièvre nearly corresponds with the ancient province of Nivernais, which was in early times a county subject to the dukes of Burgundy. Although it never had any historical importance, this country has given birth to several celebrated men. The people are in general lively, industrious, and hospitable; but ignorant, passionate, and much given to pleasure.

NIGDEH, or NIDECH, a town of Asia Minor, in the pashalic of Karamania, on a hill 47 miles N.E. of Eregli. It is defended by ancient walls, and by 3 castles; contains several mosques, a Mohammedan college, and some remains of antiquity. Pop. about 5000.

Niger.

NIGER, QUORRA, KWORA, or KAWARA, a large river of Central Africa, which has long excited the interest of geographers, and the attempts to explore which have unfortunately, in too many cases, been attended with a melancholy loss of life. The points long undecided regarding this river were—whether the large river in the interior of Africa, first mentioned by Herodotus, and afterwards by Strabo, Pliny, Ptolemy, and others, could be identified with what is now called the Quorra or Joliba, the latter being the name given to it in the earlier part of its course?—whether it lost itself in the great Lake Tschad, or terminated in the Atlantic Ocean?—whether it carried its waters underground through the Great Desert into the Gulf of Syrtis?—or whether it flowed in an easterly direction, and formed a branch of the Nile?

It is now very generally agreed that the modern Niger or Quorra is identical with the Nigeir of Ptolemy and others. Herodotus gives an interesting account of an expedition undertaken by five young men of the tribe of the Nasamones, a Libyan people who occupied the country lying between that of the Garamantes, or the modern Fezzan, and the great Bay of Syrtis. They set out for the interior, and after passing through the inhabited region and the country of the wild beasts, they traversed for many days, in a western direction, the great sandy desert, until they arrived at a country inhabited by men of low stature, who conducted them through extensive marshes to a city built on a great river, which contained crocodiles, and which flowed towards the east. This river was then supposed to be a branch of the Nile; but without going into the arguments for and against, we may give it as the now generally received opinion that they had reached the Quorra at a place where its course is eastward; and some hold that the city to which they were conducted was none other than Timbuctoo itself. Notice is taken of the Niger by Strabo; and Pliny treats of it at considerable length, as the Nigris of Ethiopia, but in a very confused manner, and as an affluent of the Nile. Mela, however, confessed that when the Niger reached the middle of the continent, it was not known what became of it. Ptolemy, who wrote later than the preceding geographers, and was better informed regarding the interior of Africa, lays down as the course of the Niger what corresponds tolerably well with what we know to be the course of the Joliba or upper part of the Quorra. He seems to have considered it as an interior river, having no communication with the sea. The celebrated Arabian geographers Abulfeda and Edrisi, and Leo Africanus, a native of Spain, all assigned to the Niger a westerly course; and the two former represented it as rising from the same source as the Nile; but Leo supposed it to take its rise in a lake situated to the south of Bornou, whence it was believed to flow westward to the Atlantic Ocean.

The early European navigators, in their discoveries on the western coast of Africa, found successively the estuaries of the Senegal, Gambia, and Rio Grande, and believed them to be the mouths of the Niger. In course of time they were tempted to explore these rivers for the purpose of reaching the far-famed city of Timbuctoo, the reputed wealth of which had excited their cupidity. These they traced till they became mere rivulets, and yet found themselves no nearer to the object of their desires. In the meantime the French geographers De Lisle and D'Anville devoted their attention to Africa. De Lisle, in a map published in 1714, gave the sources both of the Niger and Senegal—the former being made to flow eastward and the latter westward, which was an approximation to the truth. D'Anville followed up this view in his map of Africa published in 1749; and thus far a correct knowledge of the source and direction of the Niger was obtained, by its being separated on the east from the Nile, and on the west from the Senegal.

VOL. XVI.

Niger.

The formation of the African Association in England in 1788 marks the commencement of a new era in the history of African geography. The first and principal object which occupied the attention of this body was the course and termination of the Niger; and a reward was held out to the person who should succeed in determining them. We pass over the names of Ledyard and Lucas, the former having died at Cairo before accomplishing anything; and the latter having only gathered some information from the Arabs, which tended rather to perplex than to elucidate the subject. The third adventurer employed by the association was Major Houghton, who had acted as British consul at Morocco, and had thus become familiar with Moorish manners. He sailed up the Gambia to Pisania, and thence proceeded into the interior, but he there met his death without accomplishing anything of importance. The honour of determining the course of the Niger was reserved for the celebrated traveller Mungo Park. Having offered his services to the association, and been accepted, he, on the 22d May 1795, left England, and on the 5th of July reached Pisania, where he remained for some time to acquire the Mandingo language. On 2d December he began his journey, and after crossing the country E.N.E. to Yarra, and then turning S.E. through the kingdoms of Ludamar and Bambarra, he came in sight of the Niger near Sego. "I saw," says he, "with infinite pleasure, the great object of my mission, the long sought-for majestic Niger glittering to the morning sun as broad as the Thames at Westminster, and flowing slowly to the eastward." He traced its course downwards to Silla, and upwards as far as Bammakoo, an extent of about 300 miles. From the latter place he crossed the country by a more southern route than his former track, and at length reached Pisania on the 10th June 1797. At the request of the British government he undertook another expedition, and set sail from Portsmouth, fully equipped, on 30th January 1805. Pisania was again his point of departure, which he left on the 4th of May 1805, accompanied by his brother-in-law Mr Anderson, surgeon; Mr George Scott, draughtsman; five artificers from the royal dockyards; Lieutenant Martyn, and thirty-five privates of the Royal African Corps stationed at Goree; and a Mandingo, Isaaco, a priest and trader, who acted as guide. He chose the route by which he had returned on his first journey, but he had not proceeded far when the rainy season set in, and by the time that he reached Bammakoo only eleven men remained with him, the rest having either died by the way, or been left sick in charge of friendly natives, but never afterwards heard of. The expedition descended the river in two canoes to Sansanding, where Mr Anderson and some others fell victims to the climate. His last despatches are from this place. Writing to Lord Camden he said:—"I am sorry to say that of forty-four Europeans who left the Gambia in perfect health, five only are at present alive; viz., three soldiers (one deranged in his mind), Lieutenant Martyn, and myself." He added—"We had no contest whatever with the natives, nor was any one of us killed by wild animals or any other accident." He set sail from Sansanding on the 19th November, and from information since obtained, he seems to have proceeded down as far as Boussa, 650 miles below Timbuctoo, where, having been attacked by the natives, he and his companions attempted to save themselves by swimming, but were drowned.

Park had been led to adopt the opinion of Captain Maxwell, a slave trader, who had been accustomed to frequent the Congo, that that river formed the lower part of the Niger. After the time of Park this opinion continued to gain ground, and the government was at length induced, in 1816, to despatch an expedition to attempt the solution of this question. It was divided into two parts: the one, under the command of Major Peddie, was to pene-

Niger. trate across West Africa to the Niger; the other, under Captain Tuckey, to ascend the Congo. These threw no new light on our subject, and were attended with very disastrous results; the commanders and most of the men having fallen victims to the climate. More recently the travellers Laing, Caillie, Clapperton, and Richard Lander ascertained important facts regarding the Niger; but it is to the last of these that we are indebted for having pointed out the true mouth of the Niger. His first journey was undertaken as confidential servant to Captain Clapperton, and on the death of that enterprising traveller at Saccatoo on the 13th of April 1827, he brought home his journal and papers. On his return to England he volunteered to navigate the river from Boussa, the point where Park perished, to its mouth. His offer having been accepted by the government, he set out on his mission, accompanied by his brother John, and reached Boussa on the 17th of June 1830. From Boussa the Landers proceeded up the river about 100 miles to Yaori, where they arrived on the 27th of June. They commenced the descent of the river on the 2d of August; and on the 18th of November following they entered the Atlantic by the River Nun, and thus set at rest the long disputed question of the mouth of the Niger.

The return of the brothers Lander awakened anew the spirit of enterprise, and an expedition was fitted out by some merchants of Liverpool for commercial as well as geographical purposes. It consisted of two steam vessels, and the general direction of it was intrusted to R. Lander. It proceeded up the Niger as far as Rabba, and likewise for nearly 100 miles up a hitherto unexplored affluent, the Shary or Tschadda. The results of the expedition, however, were unsatisfactory to the projectors, and most fatal to those who had undertaken it, very few of the Europeans having survived. Among those who perished were the two Landers—John from the effects of the climate, and Richard from a wound received in an encounter with the natives. No further attempt of any magnitude was made until 1841, when the government fitted out three steamers built specially for the purpose. This expedition was intended to carry out, besides extended researches, various philanthropic but ill-matured schemes. It shared no better fate than its predecessors, having only reached Egga, about 50 miles above the confluence of the Tschadda, when it was obliged to return in consequence of the sickness and death on board.

In 1852 intelligence was received from Dr Barth, that on the 18th of June 1851 he had crossed a large stream named the *Benué*, or "Mother of Waters," which, from the information received from the natives, he conjectured to be the upper part of the Tschadda affluent of the Niger. He reached it at a point called Taëpe, where it is joined by the Faro, in Lat. 9. 2. N., Long. 14. E., 235 geographical miles S. of Kuka, and 415 in a direct line E. by N. from the confluence of the Tschadda with the Quorra. It was here half a mile broad, and, when crossed, was 9½ feet deep in the channel, but on their return, eleven days later, it had risen 1½ feet. The Faro was five-twelfths of a mile broad, and 3 feet deep, and by their return had increased to 7½ feet in depth. Both rivers had a very strong current, and flowed westward.

Another expedition was now resolved on to explore the Tschadda branch of the Niger, and the Admiralty entered into a contract with Mr Macgregor Laird, one of the survivors of the Liverpool expedition, to build and equip a suitable vessel for that purpose. Accordingly, an iron screw schooner, named the *Pleiad*, was built at Birkenhead. "She was of 260 tons measurement, 100 feet in length, with 24 feet beam, and her engine was of 60 horse-power. Her draught of water, when laden, was 7 feet, or 6 feet when in ordinary trim. A sailing-master, surgeon, officers,

and crew, were provided for her by Mr Laird, and it was arranged that she should be sent to Fernando Po, where the officers appointed by government should join. The peculiar features of this expedition were, first, the employment of as few white men as possible; secondly, entering and ascending the river with the rising waters, or during the rainy season; and lastly, it was anticipated that the use of quinine, as a prophylactic or preventive, would enable the Europeans to withstand the influence of the climate. Mr Laird being permitted, by his agreement with the Admiralty, to trade with the natives whenever it was practicable, provided a well-sorted cargo, and sent out persons specially to attend to this branch. The *Pleiad* having made a very satisfactory trial trip across the Irish Channel, finally took her departure from Dublin on the 20th of May 1854." The expedition set out from Fernando Po on the 8th of July, and four days later entered the Nun branch of the Niger. In the beginning of August they reached the confluence of the two great rivers, speaking of which, Dr Baikie says,—“From our anchorage at the confluence, near the Sacrifice Rock, as well as from the heights of Mount Pâtte, the Châdda appeared a much nobler and finer stream than the Kwôra. The latter seemed small and narrow, and could be seen pursuing in the distance its meandering route from the northward, while full in front comes pouring from the E. the broad, the straight-coursed Châdda. The natives allege that there is a difference in the colour of the two streams, and hence the Kwôra is named in Hanasa *Fari 'n rua*, or the 'White Water,' while the other is known as *Baki 'n rua*, or the 'Black Water.' I found the temperature of the former to exceed that of the latter by from half a degree to a degree of Fahrenheit." The *Pleiad* ascended the Tschadda 250 miles above the point reached by the Liverpool expedition, and within about 50 miles of the confluence of the Benué and Faro where crossed by Dr Barth; and returned to Fernando Po on the 7th of November. The party numbered 66 persons (12 Europeans, and 54 persons of colour), and though they had been 118 days on the river, very little sickness had been experienced, and no life lost.

Niger. The Quorra, or rather the Joliba, though its source has not been actually explored, is said to rise in Mount Loma, one of the Kong Mountains, in Lat. 9. 15. N., Long. 9. 36. W. Its course is at first N., then N.E. to Curuassa, about 100 miles from its source, where it was crossed by Caillie, and found to be, before the inundation commenced, 900 feet in width and 9 in depth, with a current of 2½ miles an hour. Before reaching Bammakoo, it receives the Tan-kisso and Sarano, both large streams; and at Bammakoo it commences its course over the plain of Bambarra, flowing still in a N.E. direction. It pursues the same course till it reaches Jenne, when it takes a bend nearly due N., flowing in that direction till it arrives at Lake Dibbie, where it reverts to the N.E., and continues in that direction till it reaches Timbuctoo, where the Quorra proper commences. Caillie navigated the river from Jenne to Timbuctoo, and represents the banks between these places as low and marshy. Below Lake Dibbie, which is of considerable size, the river is very deep, and from half a mile to a mile in breadth, with a considerable current. Near Kabra, the port of Timbuctoo, it divides into two branches; the larger of which is about three-fourths of a mile broad, and the smaller about 100 feet broad, but very deep. They appear to unite at no great distance farther down; but from Timbuctoo to Yaori very little is known of this great river, except that its general direction seems to be S.E. From Yaori to the sea it was navigated by the Landers, and was found to flow at first nearly due S., then to take a rapid bend to the E., and afterwards gradually to return and take a S.S.W. direction to the Atlantic, which it enters by 22 mouths, the principal of which is the Nun.

Niger
||
Nijne-Novgorod.

NIGER, C. PESCENNIUS, a Roman general, was born at Aquinum in Italy in the former half of the second century, and rose from a low rank in the army to be governor of Syria. In this office his graceful and athletic frame, his soldier-like accomplishments, and his rigid enforcement of discipline, secured the esteem of the soldiers; while his mild but impartial rule rendered him a favourite among the provincials. Accordingly, on the assassination of Pertinax in 193, he was proclaimed emperor by the united voices of the people of Asia and his own army. The intelligence that Septimius Severus was also up in arms for the crown soon hurried him into action. He marched westward from Antioch, securing the most important Asiatic cities, and despatching troops to occupy Thrace and Northern Greece. But the chivalrous unsophisticated soldier of Syria was no match for the wily and rapid Severus. His troops were finally routed at the Gulf of Issus, near the Cilician gates, and he himself was sacrificed to the revenge of his victorious rival A.D. 194. (See ROMAN HISTORY.)

NIGRITIA, or **SOUDAN** "The Land of the Blacks"), are names applied to the central regions of Africa; and, as used by Europeans, include the country lying south of the Sahara, and north of 6. N. Lat., bounded by Egypt and Abyssinia on the E., and by the nations on the western coast on the W. Until near the close of last century little was known of this extensive country; but in 1790 Houghton, who was the first European traveller in Central Africa, entered Nigritia from the west; and since that time several other discoverers have explored the western and central parts of this region, though the eastern part has not yet been visited by travellers. The principal mountains in Western Nigritia are the Kong chain, which stretches from W. to E. along the south of the country; and the principal river is the Niger, Quorra, or Joliba. The land is generally flat; and being watered by the annual overflowing of the rivers, as well as by the rains, there are some tracts of considerable fertility, on which maize, millet, rice, tobacco, cotton, &c., are raised. The climate is very hot and sultry, except during the rainy season, which extends from August to October. Central Nigritia consists of a mountainous and a flat region, the former lying to the W., and the latter to the E., of the 11th degree of E. Long. The mountains do not probably rise above 1000 or 1200 feet above the sea, and the country between them is occupied with forests and marshes. The level part of this district extends round Lake Tschad, and is watered by its tributaries. It is one of the largest tracts of inland alluvial ground in the world. The soil is very fertile, but the rank vegetation renders cultivation difficult; and the climate, though hot, is not unhealthy. Nigritia is divided into several smaller states, of which the principal are Bambarra, Timbuktu, Houssa, Bornu, Baghermi, Waday, Darfur, and Adamanua. (For an account of these, see AFRICA.)

NIJAR-Y-HUEBRO, a town of Spain, in the province of Almeria, and 14 miles E.N.E. of that town. It is ill built, and has a church and two schools. There are dye-works, and manufactures of woollen stuffs and pottery. Some trade is carried on in corn, cattle, barilla, and cloth. Pop. 5820.

NIJNI-NOVGOROD, or **NISHNI-NOVGOROD**, commonly contracted to *Nijegorod*, a government of Russia, between N. Lat. 54. 30. and 57. 5., E. Long. 41. 45. and 46. 15. It is bounded on the N. by Kostroma and Viatka, E. by Kazan and Simbirsk, S. by Penza and Tambov, and W. by Vladimir. Its length is 185 miles; greatest breadth, 136; area, 18,680 square miles. The surface is generally flat, but diversified in some places by undulating heights, which nowhere rise above 500 feet from the sea. The prevailing geological formation is limestone, and iron is the only metal found here. A sandy soil, much mixed with vegetable mould, forms the greater part of the surface,

which is very fertile, and produces plentiful crops of corn, so as to serve as the granary of Russia. The principal river is the Volga, which traverses the government from W. to E., making a bend towards the S. It receives in the government the Oka, Kulma, Kirsenez, Sara, Verluga, and Alatyr. In 1849 there were 4,689,798 acres of arable land, 729,384 of meadow land, 5,105,469 of wood, and 1,243,109 of waste land. Farming is carried on here in a much superior style to what prevails in most parts of Russia, and the farmers are distinguished alike by their skill and industry. Besides corn, the principal crops raised are hemp, flax, hops, peas, and beans; and considerable care is bestowed on the cultivation of fruit,—apples and cherries especially being remarkable alike in quantity and quality. The forests of this country are a great source of wealth, on account of the abundance of excellent timber which they contain, of which oak, lime, pine, beech, and alder are the principal kinds. The breeding of cattle is also carried on, though not to such an extent as agriculture; and there were in 1849 in Nijni-Novgorod 326,425 horses, 273,863 horned cattle, 475,801 sheep, 121,803 swine, and 1128 goats. The horses are the best that are bred in Russia; and the horned cattle are also of good breed. Although there are but few large manufactories in the government, it is inferior to none in the extent to which the people are engaged in the pursuits of manufacture; for most of the villages are filled with artizans, who produce on a small scale a great variety of articles. Spinning, weaving, and pottery, are chiefly carried on in these small establishments; and among the more extensive productions leather, cloth, cordage, soap, candles, iron, steel, &c., are the principal. There is an active trade in the exportation of corn, flour, hemp, flax, horses, and manufactured articles; and the importation of iron, salt, brandy, wine, &c. The commerce of the country is greatly facilitated by the large navigable rivers by which it is traversed. Pop. (1849) 1,124,251.

NIJMI-NOVGOROD, the capital of the above government, stands at the confluence of the Oka with the Volga, on the right bank of the latter river, 259 miles W. by N. of Moscow. It consists of three parts: the upper city, which stands on a hill between the two rivers; the lower city, which extends along the bank of the Volga; and a suburb, stretching along that of the Oka. The highest part of the upper city, which immediately overhangs the river, is occupied by the kremlin or citadel, which is surrounded by a lofty wall flanked with towers, and contains the principal buildings of the town. These consist of two cathedrals; the governor's palace, a modern building, commanding an extensive view; a Protestant church; and other public edifices. The town itself is pretty well built, though for the most part only of wood. There is an irregular public Place in the upper town. Nijni-Novgorod has 42 churches, 8 convents, a seminary for schoolmasters, and several schools. Manufactures of malt, beer, leather, cloth, soap, candles, copper and iron ware, &c., are carried on; but the chief importance of the place is derived from the great fair which is held here annually, and lasts from the latter half of July to the end of August. The place of these fairs is a low tract of ground, of a triangular shape, lying between the Volga and the Oka, and separated from the town by the latter river. At all other times of the year this place is quite deserted, and sometimes overflowed by the rivers; but as the fair is held at the dry season, it is then in no danger of this, and always presents a very busy and animated scene. It is laid out in broad and regular streets, crossing each other at right angles, and having in general covered arcades of iron along the sides in front of the shops. It is drained by a system of underground sewers, made of hewn stone, at a great cost. Access is gained to them at several points by means of staircases; and water is con-

Nijni-Novgorod.

Nikolaiev
Nile.

veyed through them from the rivers several times a-day. The only communication with the town is by means of a bridge of boats across the Oka. The governor of the province resides during the continuance of the fair in a handsome building in the centre; and there is a Russian church and a Mohammedan mosque within the precincts of the fair. This part of the market is entirely built of stone, and contains 2521 shops, forming 60 blocks of buildings. This forms the inner market, and it is separated from the outer by a canal, which is crossed by four bridges. The outer market is built of wood, and contains upwards of 2000 booths, built in a very substantial manner. In the inner market are to be found chiefly the more valuable articles of manufacture; such as cloth from Moscow, silk from Persia, furs from Siberia, Astrachan, Buchara, and other places; tea from China; and other goods. Here also there are not such great crowds collected as in the outer market, but the most extensive business transactions are carried on. The outer market, which has more the character of a fair, is generally much crowded with people from all parts of the world, and contains most of the raw material and articles of small value. The rivers during the continuance of the market are crowded with vessels of all sorts and sizes, busily engaged in loading and unloading their cargoes; and a great number of people live entirely on the water. The whole number who attend the market, from first to last, is estimated at 200,000; those collected together at any one time being not more than 20,000. The amount of articles bought and sold is immense. The quantity of iron collected here in 1843 was about 60,000 tons; of copper, 800 tons, valued at more than L.200,000; besides which there were 39,000 chests of tea, and many other articles. Pop. of the town (1849) 30,710.

NIKOLAIEV, a town of Russia, in the government of Kherson, occupies a large extent of ground at the confluence of the Ingul and the Bug, 36 miles N.W. of Kherson. It has wide and regular streets, lined with very well built houses, one storey high, which have in general large gardens attached to them. It is surrounded by fortifications; and has a fine boulevard, planted with trees, along the edge of the river. The public buildings are numerous; and among them the most important are,—the cathedral, a modern edifice with a richly-decorated interior; the town-hall; the observatory; the admiralty; the naval barracks; and naval hospital. The dockyards are very extensive, and provided with machinery principally of British construction. The town has also numerous schools for naval cadets, pilots, ship-builders, &c. Nikolaiev is the principal station of the Black Sea fleet, and the residence of the admiral of it. It was founded in 1791, and at first made rapid progress; but it is now in a declining state, owing to the want of good water and timber, the competition of Odessa, and other causes. It is now kept up principally by the support of the government. Pop. (1850) 39,338.

NIKOLSBURG, a town of Moravia, in the circle of Brünn, and 27 miles south of that town, is built round the foot of a rock, on which stands a castle flanked with high towers. It has ill-paved and dirty streets; and the principal buildings are, a handsome church, two synagogues, and a Piarist college. Manufactures of woollen and linen cloth are carried on here. Pop. 8000.

NILE. The whole subject of the geology, inundation, levels, volume of water, deposits, and agricultural action of the Nile in the northern portions of its course, has been so very fully treated of in the article EGYPT (see vol. viii., pp. 424-6), that we shall confine ourselves in the present article to the southern and less known portions of this great river, and endeavour to throw some further light upon its probable sources and course—that great problem which has puzzled the geographers and men of science in all ages, and baffled the attempts of the ancient priests of the Nile,

of the Pharaohs, of the Phœnicians, the Greeks under the Ptolemies, the Romans under the Cæsars, and, in much later times, of Bruce, and the numerous expeditions under Mohammed Ali and Ibrahim Pasha.

Nile.

The general features of the Nile, as you ascend it from the second cataract at Wady Halfa to the junction at Khartoum, undergo no material change. From time to time the river flows through high rocks of dark syenite, and four cataracts (more properly called rapids) impede its smooth course for a few miles; but a detailed description of its banks would be uninteresting: desert wastes and fertile islands—sandy hills surmounted by doum palms (here taking the place of date trees), and narrow strips of luxuriant vegetation—villages deserted by a too-heavily taxed population, and large towns, the capitals of their provinces,—characterize the scenery. The crocodile increases in number, as in size, and the ibis begins to appear. Near Berber, about 100 miles north of Khartoum, the hippopotamus ceases to be a rarity, and the white crocodile is occasionally to be seen.

In Lat. 21. N. the river makes a great bend to the eastward, and the traveller southwards crosses the desert of Bayiouda, which skirts the western banks of the Nile, a most beautiful ride of 250 miles through a garden rather than a desert. The path lies through woods of good-sized trees—mimosas, myrtles, acacias, hung with tropical parasites; while the ground is covered with the senna, colocynth, ice-plant, and many strongly-scented shrubs. From the dead roots of fallen trees rich orchids spring, and an infinite variety of gay-coloured birds are flitting about overhead. Partridges and gazelles of several descriptions abound, and the whole country is thickly peopled with many tribes, who are in the habit of travelling from well to well, accompanied by large herds of sheep, goats, and camels, in search of pasture.

The great desert of Nubia borders the eastern bank of the Nile, and is of a very different description. With the exception of some high rocks of quartz and granite, near the well of El-Morah, the route from Aboohamed to Korusko, a distance of 350 miles, lies through a perfectly level, hard, gravelly plain; no vegetation of any sort exists, save on the immediate banks of the river, and the only well is that of El-Morah, above mentioned.
